The same is true of a multicrystalline block of ice in which the crystals are closely interlocked and oriented at random. If a small load is applied to a block of such ice, compression is found to go on rapidly at first and then more slowly until it settles down to a constant rate, known as the rate of quasi-viscous creep. Behaviour of this type is commonly observed in metals, and ice near its melting point merely differs from them by requiring very much smaller loads to produce the same rate of compression.

The important feature from the glaciological point of view is the dependence of the creep-rate on the load and on the temperature. These relationships have recently been discovered by Glen, whose elegant and painstaking experiments provide the key to our understanding of glacier flow[2]. At constant temperature and with loads of between 1 and 10 kgm./cm.^{2} the creep-rate varies as the 3½rd power of the load. If the load is kept constant at 6 kgm./cm.^{2} and the temperature varied, the creep-rate drops by a factor of five between 0° and −1° C. and by a factor of 10 between −1° and −10° C. (Fig. 2). From the temperature-dependence of the creep-rate, Glen was able to show that creep is essentially due to the thermal motion of the water molecules in the crystal which constantly try to change their places; an external load merely provides the extra push needed to give direction to this general movement.

These results have been obtained with small specimens of ice made in the laboratory. Would they necessarily hold if the scale were enlarged several thousand times and the block of ice assumed the dimensions of a glacier? This point has been tested in the following way. Any cavity hollowed out of a glacier contracts under the weight of the overlying ice layers. If a tunnel is dug into a glacier and its rate of contraction measured at different points along its length, the relation between creep-rate and load can be calculated.

Suitable tunnels have been dug in Norway by a Cambridge expedition under the leadership of McCall and Lewis, and in Switzerland by engineers of the West Swiss Electricity Company under the guidance of Haefeli[3,4]. The results of their measurements have been used by Nye to derive a relation between creep-rate and shear stress which is in reasonable agreement with Glen's laboratory tests[1,3].

$\dot{\gamma} = k\tau^n$. Laboratory $k = 0{\cdot}4$ Tunnels $k = 0{\cdot}33$
At 0° C. $n = 4$ $n = 3$
$\dot{\gamma}$ = shear strain per year; τ = shear stress in bars
k and n = empirical constants.

Application to Glaciers

In applying this law to glaciers, it must be realized that it can be used only to derive the amount of flow *within* the ice; it provides no information about the speed of sliding on the glacier bed. What can be calculated is the difference between the velocity at the surface u_s and the velocity at any depth u_d[5]:

$$u_s - u_d = \frac{k}{n+1}\, d\tau^n. \qquad (1)$$

If this relation is plotted for a glacier four times as wide as it is thick with a slope of 1 : 10 (Fig. 3), it is seen that no perceptible flow within the ice would occur at a depth of less than 100 m.; on the other hand, at a depth of 1,000 m. the annual velocity would exceed 30 km., which is more than anything known to-day.

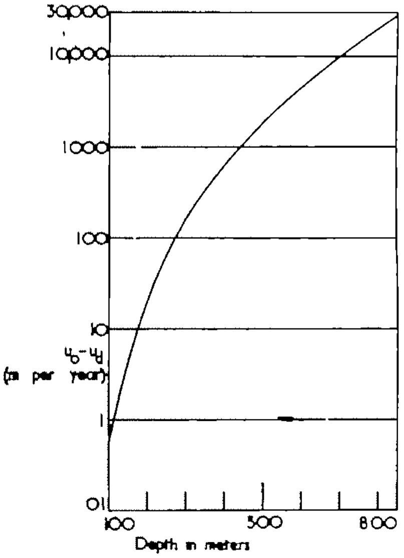

Fig. 3. Difference between the surface velocity u_s and the velocity u_d at a depth d calculated from Glen's flow law. The glacier is assumed to have a slope of 1 : 10 and to be four times as wide as it is deep

A glacier tongue has to remove an amount of ice equivalent to the annual net accumulation of snow which the entire glacier receives. If we take the accumulation area of a typical Alpine glacier as 10 km.², and the net accumulation as 50 cm. of ice per year, then the volume of ice to be removed by the glacier tongue in one year is 5 × 10⁶ m.³. On the basis of the graph the volumes removed by glacier tongues of different depth are:

d	V
100 m.	10,000 m.³
250	6 × 10⁶ m.³
1,000	10¹¹ m.³

Thus to remove the right volume of ice, glacier tongues of slope 1 : 10 would have to be between 200 and 300 m. thick. Of known glaciers of this slope, the Grenz Gletscher is 290 m. and the Rhone Glacier 200 m. thick, which shows that the values predicted by the flow law are about right.

Another way of testing the equations of flow is to see if they predict reasonable surface velocities for glaciers of known depth. For this purpose u_s/d has been plotted against the shear stress for various glaciers (Fig. 4). The observed velocities are on the average about twice those predicted by Glen, the difference being presumably accounted for by sliding of the glaciers over their beds; but clearly the agreement is as good as can be expected. A further interesting feature of this graph is the small variation in the shear stresses at the bed of different glaciers, which all lie between about 0·5 and 1·5 kgm./cm.². This shows that the shear stress at the bed needed to produce a velocity of flow sufficient to balance the precipitation at the head of a glacier is generally of the order of 1 kgm./cm.², at least in Alpine glaciers which are at the melting point throughout most of their mass.

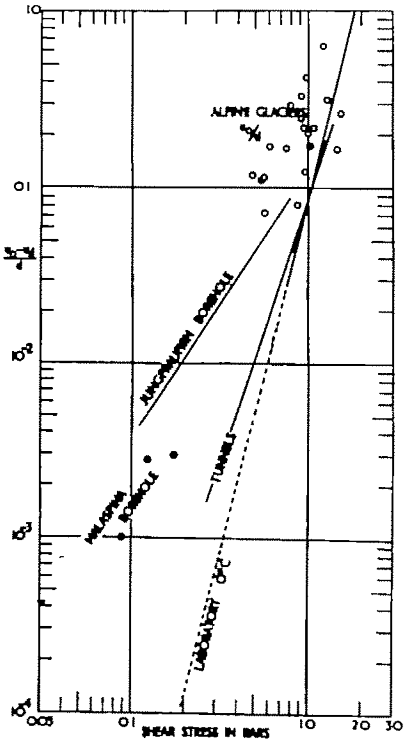

Fig. 4. Comparison of the observed surface velocity of Alpine glaciers, and the velocity distribution measured inside glaciers, with the corresponding quantities predicted from Glen's flow law, using equation (1). The broken part of the 'Laboratory' line is extrapolated

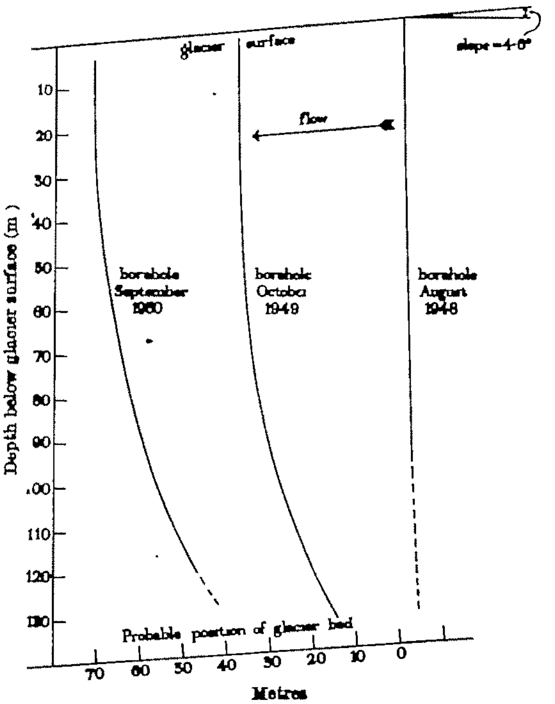

Fig 5. Velocity distributions along a vertical line through the Jungfraufirn. The lines show the position of the borehole in three successive years (Gerrard, Perutz and Roch, *Proc. Roy. Soc.*, A, 213, 553 (1952))

Direct Measurement of Vertical Velocity Distribution

The most certain method of testing the equations of flow, together with the many theories of flow previously proposed, is the direct measurement of the velocity distribution along a vertical line through a glacier. The first experiment of this kind was done by Gerrard, Roch and myself⁹, using a method which had been suggested to us by Sir Edward Bullard. A vertical hole is drilled into a glacier and lined with a flexible steel tube. This tube is left in the glacier, to be tilted and bent by the flowing glacier according to the different velocities prevailing at different depths. If the angle of tilt of the tube is measured all along its length at the start of the experiment and again after suitable intervals of time, the difference between the surface velocity and the velocity at any depth can be calculated.

This experiment was done on the Jungfraufirn, a few hundred yards below the Jungfraujoch Research Station. A hole 400 ft. deep reaching from the surface to the bed was made with an electric heating element and lined with a 3-in. steel tube. The inclination of the tube was measured with an electrically recording pendulum instrument designed by Jason and Broad.

The results of the pipe experiment can be summarized in one illustration which shows the position of the tube in three successive years (Fig. 5).

Of the surface velocity of 35 m. per year, roughly one-half is accounted for by sliding over the bed and the other by flow within the ice. The rate of flow decreases regularly from the surface downwards, and there is no sign of a fast-flowing layer in the interior of the glacier. The rate of shear within the ice increases too fast with depth for ice to be a liquid of constant viscosity and approximates to a relation where the rate of strain is proportional to the 3/2 power of the shear stress.

Our method of measuring the velocity distribution in glaciers has been taken up by two groups in the United States: one under Mr. M. M. Miller, working in the Juneau Ice Field, and the other under Prof. Robert Sharp[7], working on the Malaspina Glacier, both in Alaska. Sharp's first results with a thousand-foot borehole have recently been published. The inclination of the glacier at the site of the borehole is only 22′, so that the deformation of the borehole is slow. It will take several years to get definite results; but in the meantime the preliminary measurements can be compared with those obtained on the Jungfraufirn and with the velocity distribution predicted from Glen's flow law.

The quantity which is most conveniently compared is the flow within the ice, $u_0 - u_d$, divided by the depth d (Fig. 4). At shear stresses of the order of 1 bar, the agreement between theory and experiment is good, but at lower stresses the glacier ice is deformed much faster than Glen's flow law would lead us to expect. This may be due to some extent to the high air-content of the ice on the Jungfraujoch and the high water-content of the ice in the Malaspina glacier; but the most important part of the discrepancy is probably due to a phenomenon which is of the utmost importance in glacier flow and which had never been clearly understood until it was pointed out in a brilliant theoretical paper by Nye[8].

Longitudinal Compression and Extension

The shear stresses shown in Fig. 4 have been calculated on the assumption that the glaciers descend by simple shear on an evenly inclined plane. In reality, glacier beds consist of a succession of hollow basins alternating with steep steps. When a glacier descends over a step, its speed rises and its depth is reduced, and when the bed flattens the converse process occurs, just as a stream tends to be shallow when it descends over rapids and deep as it flows through a plain. Nye[8] showed that the thinning and thickening of the glacier introduces additional strains which cause the velocity distribution to be distorted from a straight line—the solution for an ideally plastic glacier descending on an evenly inclined bed—to an ellipse. This process would produce just the kind of departure from Glen's flow law which is actually observed.

The importance of Nye's theory lies in the fact that it suggests an explanation for the peculiar erosive power of glaciers, namely, the hollowing-out of corries and basins which are so characteristic a feature of the once glaciated landscape. Nye suggests that the banking-up which occurs when a glacier is compressed might actually lead to failure along a series of planes where the stress is greatest. These planes intersect the surface at 45° and approach the bed asymptotically. Nye suggests that these thrust planes might pick up debris from the glacier bed and carry them up towards the surface, rather like gravel being picked up from the ground when snow is pushed from the doorstep. When the glacier is stretched by descending over a convex slope, the converse set of thrust planes would be formed. I should like to emphasize that although thickening and thinning, that is, the banking up and stretching of glaciers, are essential features of their flow, these might equally well take place by uniform compression and extension of the ice.

The thrust planes are an attractive feature because they explain erosion; but they are not an essential feature with a flow law of the type proposed by Glen. Flow along a thrust plane inclined at 45° to the glacier surface was found by Seligman and myself[9] in a grotto in the Eigergletscher, where it went hand in hand with uniform deformation of the ice underneath; but this thrust plane contained no rock debris. It will be interesting to see whether a thrust plane containing such debris can be discovered, and confirmed by direct measurement of the rate of overthrusting.

Rotational Slip

There is one particularly simple way in which a hollow basin might be ground out by a glacier. If Nye's two types of thrust planes come sufficiently close together, the entire glacier could rotate about a horizontal axis, a type of motion first envisaged by Ward and Lewis.

It was in an attempt to test this idea that McCall assembled a large party of Cambridge undergraduates and inveigled them into digging two tunnels from the surface to the bed of the small Skauthoe Glacier in Norway. By surveying the movement of different points along the glacier surface and along the length of the tunnels, McCall[3] showed that the entire glacier flows by rotation around a horizontal axis. The thickness of this glacier nowhere exceeds 60 m., which is too little for appreciable flow within the ice to occur. Most of the flow, in fact, seems to be concentrated in a thin layer of sandy ice near the bed, which appears to be hollowed out largely by friction, and thrust planes within the ice are absent.

McCall's strenuous experiment has broken new ground by giving us a glimpse of glacial erosion in action, together with a quantitative picture of every detail of a glacier's movement.

Summing up, we may say that the flow law of ice found in the laboratory provides a new basis for research on the flow of glaciers. Its general validity in glaciers has been verified by measurement of the rate of contraction of tunnels and by comparison of the surface velocities and depths of Alpine glaciers with the values predicted from the flow law. The vertical velocity distributions in glaciers agree with the flow law at shear stresses of the order of 1 bar, but depart from it at smaller stresses. The departure may be explained by the longitudinal compression and extension which glaciers undergo in response to changes in the shape of their bed. Longitudinal compression may also give rise to slip along thrust planes in the course of which debris might be picked up from the bed and shifted towards the surface. This is suggested by Nye as a possible mechanism of glacial erosion[10]. Erosion of a corrie by rotational slip of an entire glacier has been demonstrated in Norway.

NORTH ATLANTIC WEATHER SHIPS

PRESS reports show that the United States Government has notified the International Civil Aviation Organization of its intention to withdraw the weather ships which it maintains in the North Atlantic when the present international ocean weather ship agreement expires on June 30, 1954.

Ocean weather ships occupy 'fixed' ocean stations and perform several duties. These duties include the making of surface and upper-air meteorological observations at frequent definite intervals and transmitting the data by radio for use in weather forecasting; navigational aid to aircraft in flight by giving radio bearings and radar fixes, transmitting the latest surface and upper-air observations to aircraft on request and acting generally as relay stations between aircraft and air-traffic control centres; air-sea rescue duties; and making oceanographic and other scientific observations as opportunity permits. The ships are located at positions carefully selected for best fulfilment of their meteorological and navigational aid duties from the Norwegian Sea to between the Azores and the United States.

The North Atlantic weather station scheme was arranged at a conference of the International Civil Aviation Organization in 1946 and modified in 1949 by reducing the number of stations from thirteen to ten. The total cost is shared among the participating nations in proportion to the number of flights made across the Atlantic by their civil aircraft.

At present, the United States wholly maintains four stations, the United Kingdom one and Norway with Sweden one. The Netherlands assist in the operation of one station with the United States, one with Great Britain, and one with France; Canada assists the United States in operating one; and certain other nations contribute financially to the scheme. The number of ships needed to man the stations is at least two per station and may be three according to distance from base. The United States employ coastguard cutters, Great Britain and Norway "Flower" class corvettes, and the other participating countries use frigates in the weather ship service.

Besides those in the North Atlantic, the United States, Canada, and Japan maintain weather ships in the North Pacific under an entirely separate arrangement.

The cessation of reports from the American weather ships would handicap weather forecasters working for the North Atlantic air routes mainly by the loss of upper-air information. Location of the often rather narrow belts of high wind, the so-called jet-streams, which may seriously increase the flight-times of aircraft flying against them, is a matter of much concern to the North Atlantic forecaster. Pre-flight planning of the fuel to be carried by trans-Atlantic aircraft is based on the forecast upper winds. To obtain the same degree of safety with less certain knowledge of the winds to be expected would necessarily mean on many occasions that airlines would have to sacrifice paying load to carry more fuel as an insurance against the increased risk of encountering headwinds stronger than forecast. This would be a direct financial loss to the airlines of all countries concerned in North Atlantic flying.

Valuable observations are regularly made and transmitted by voluntary observers on merchant ships, but not so frequently as by the meteorologists on weather ships, and, in particular, they include no upper-air observations. Merchant ships are, of course, almost always moving, and even with the good organization in force for collecting their reports, large areas without observations on the weather maps are inevitable.

Apart from the immediate use of weather ship observations in forecasting, the detailed logs are interchanged among the nations for the building up of a comprehensive climatology of the North Atlantic from the surface to heights of more than 50,000 ft. Never before have continuous weather records from fixed ships in mid-ocean been obtained. Further, the ships provide admirable laboratories for special investigations in oceanography and other geophysical subjects, and small expeditions from university research institutes have worked in them.

It is to be hoped that a new agreement providing for the maintenance of some, at least, of the American stations will be reached before the present one expires.

A WHALE-MARKING EXPEDITION

By Dr N. A. MACKINTOSH, C.B.E.

National Institute of Oceanography, Wormley, Surrey

THE marking of whales can assist nearly all investigations on the populations and life-cycle of whales, it seems the only satisfactory method of gaining information on many aspects of their distribution and movements, and it was carried out on a considerable scale by the Discovery Committee before the Second World War. A previous article in *Nature*[1] gave a summary of the information already obtained from recovered marks, and directed attention to the need for more marking, both in the Antarctic and in other regions. It was noted that the National Institute of Oceanography (which now includes the Discovery Investigations) could not now meet the cost of special marking expeditions; but the hope was expressed that some means of continuing the work would be found.

The generosity of a number of whaling companies has now led to such an expedition, and a ship is on the way to the Antarctic to mark whales during some weeks immediately before the opening date (January 2) of the whaling season of 1954. The marking has been organized jointly by the National Institute of Oceanography and the Norwegian State Institute for Whale Research.

The importance of whale marking had been endorsed at recent meetings of the International Whaling Commission, and after correspondence with the National Institute the former chairman of the Commission (Ambassador B. Bergersen) and the secretary of the Association of Whaling Companies (Mr. E. Vangstein) took the initiative in approaching the whaling companies. In the summer of 1953 a number of these companies (British, Norwegian, Dutch and South African) agreed to share the cost of about a month's marking by the modern whale catcher *Enern*, owned by the Norwegian company, A/S Thor Dahl. Whale catchers hitherto had not been the ideal ships for whale marking on account of their relatively short cruising range, which tended to restrict marking to the immediate field of hunting. But the *Enern* is a powerful new diesel-driven vessel with a cruising-range which enables her to sail more than a month in advance of the parent factory ship, from which catchers are normally refuelled.

The *Enern* is expected to reach the edge of the pack-ice in the later part of November, and to mark whales between the Greenwich meridian and South Georgia in the Dependencies of the Falkland Islands. Prof. J. T. Ruud, director of the State Institute for Whale Research, is in charge of the work, and sailing with him are Mr. R. H. Clarke, of the National Institute of Oceanography, Mr. Per Øynes, also of the State Institute, and Mr. van Utrecht, of the Netherlands Whales Research Group. December is a little early for finding the maximum number of whales, but on the other hand the work will be done by a much more powerful vessel than has yet been used for whale marking, and she is commanded by an experienced whaler, Captain M. Marthinsen. Much depends, however, on the weather.

Very little marking has been done in the Antarctic since the War, and of the pre-war marks only small numbers are now being recovered each year. The main object of the present cruise is simply to increase the number of marked whales at large, and hence the number of marks recovered; but it is also intended to test the value of certain modifications to the standard 'Discovery' mark, which have been devised by Prof. Ruud and his colleagues to improve their effectiveness, and to estimate the chances of marks being overlooked when the carcasses are treated at the factories. In July this year some experiments were made by Prof. Ruud, Mr. Clarke, and Mr. A. Jonsgård at a whaling station at Steinshamn in Norway. Preliminary tests with the modified marks showed that they were worth extensive trials on a whale-marking voyage, and examination of the carcasses of marked whales and the position in which a mark is lodged after penetrating the blubber gave further evidence that there is little risk of injury to the whale. An account of these experiments has already been published[2]. It is hoped that with improved efficiency in the recovery of marks, the ratio of marks recovered to marks fired will come nearer to the ratio of total whales killed to total whales in the population. The latter ratio is at present unknown, and it is naturally of great importance. Large numbers of recovered marks are needed, not only to make the ratio of recovered marks more significant but also for studies of migration, of the rate of dispersal or interchange between the populations of different regions, and of the age and rate of growth of whales. Of course, a single new marking voyage will not dispose of all these problems, but it is hoped that it will lead at least to some progress in the investigation of this interesting mammalian population and assist the work of the International Whaling Commission.

For subsidiary work during the voyage, especially for observations on sea temperatures and the shoals of krill (*Euphausia superba*) on which whales and other animals feed, the *Enern* is equipped with a sea-thermograph, a 'fish-finder' echo sounder, a bathythermograph, and a 1-metre townet.

It has been arranged that the National Institute of Oceanography will act as co-ordinating body, and will receive all recovered marks. The Norwegian Institute will receive duplicates of all such data, and the two organizations will co-operate in examining the material. A report on the voyage will be sent to the International Whaling Commission and to the whaling companies participating in the scheme.

PHYSIOLOGY OF ATHLETIC TRAINING

ALTHOUGH a large amount of time, effort and money is expended on the training of human and animal athletes whose subsequent performances are witnessed in the aggregate by thousands of spectators, it was probably the inherent interest in the subject which led the Physiology Section (I) of the British Association to devote a whole day at the Liverpool meeting to a symposium on the "Physiology of Athletic Training". The methods of training both men and animals are mainly empirical; but by having a panel of speakers made up of physiologists, active athletes, trainers and coaches of both animals and men, it was hoped that the papers and subsequent discussion would show what assessment, on a physiological basis, could be made of training methods.

Middle- and long-distance running was taken by Prof. A. Hemingway (University of Leeds) as a fairly straightforward example of athletic performance. It requires skill, but not in the sense of using specialized techniques of handling implements or of employing strategy and tactics as in complex games. The limitations to performance in running are ultimately dependent on chemical reactions in muscle. Some of the reactions are anaerobic; but they can only be used to a limited extent. If oxygen is available the overall reactions can be aerobic, and the extent to which they are used is dependent upon the oxygen supplies to the muscles. If the rate of energy liberation outstrips the available oxygen supplies, then part of the energy must be supplied by the anaerobic mechanisms. But as these are limited, fatigue must ultimately ensue, the period elapsing before its onset depending on the rate of energy liberation. The fundamental problems of the athlete are to convert his energy into locomotion with maximum efficiency and to provide as large a proportion of the energy as possible by aerobic mechanisms. To what extent does training help in solving these problems?

Comparisons between trained and untrained men show great differences in their ability to take up oxygen. The highest rate of oxygen uptake measured on a trained athlete is 5·3 l./min. when breathing atmospheric air at normal pressure. The ability to transport oxygen at this rate from the lungs to the working muscles seems to depend upon a large output of blood from the heart. Such differences as there are between the capacity of the lungs, the rate at which they can be ventilated, or the composition of the blood, in trained and untrained men are insufficient to explain the discrepancy between their ability to take up oxygen. The main difference seems to be in the output of the heart. Recent advances in the technique of measuring the output of the heart make it possible to estimate that the maximum output may rise to about 40–50 l./min. in a first-class middle-distance runner. The severe training methods used by some long-distance runners increases the strength of both the skeletal muscles and the heart. The athlete makes optimum use of the oxygen which is available through this large blood output by running usually at a constant pace and by employing an economical style. Recent Scandinavian work illustrating the relationship between stride-length and efficiency of running was quoted by Prof. Hemingway. For a given pace there is an optimum length of stride. Preliminary exercise —'limbering-up'—improves subsequent performance and seems to produce its effects through a local increase in temperature of the working muscles. Whether the change in temperature directly affects the properties of the muscle or operates by producing an increase in blood flow is still undecided.

That lack of oxygen is the main factor limiting the distance runner was stressed by Mr. Roger Bannister (St. Mary's Hospital Medical School, London), who described experiments which he had performed in Oxford upon himself and athletic colleagues. The subjects undertook severe standardized exercise on a treadmill, while breathing mixtures of oxygen and air. They were exhausted after running for about eight minutes with atmospheric air; if oxygen was added to give 33 per cent concentration, the performance was improved, while with 66 per cent oxygen the runners appeared to be able to continue indefinitely. It was suggested that because of vascular shunts in the lungs, there might be an actual reduction of the oxygen saturation of the arterial blood during severe exercise which was mitigated by enriching the air with oxygen. If so, training might be regarded as an alternative to the use of an oxygen mask!

Training methods in current use were described by Mr. G. H. G. Dyson (chief coach, Amateur Athletic Association). With the aid of 'loop films', which enabled the audience to have a particular phase of movement projected repetitively, he showed the characteristic styles of champion long-distance runners, emphasizing how the stride is developed from a vigorous thrust, or drive, of the back leg. The back leg, often flexed at the knee with the foot above the level of the knee joint, is then swung forward in pendular fashion, and the runner lands almost flat-footed with the foot very little in front of the body. The length of stride is rather shorter than might be expected from body height. Training aims at developing strength, endurance, efficiency of movement and judgment of pace. Although the methods of various successful athletes may appear to differ, they are very similar in their essentials. Early training for the development of muscular strength might consist, as with the Scandinavians, in running in snow, or cross-country running, or even running in heavy boots. This would be followed by later training in which the athlete would obtain practice in running at a speed appropriate to his race, interspersing his faster running between longer periods of slower running. Thus, in training on a track, an athlete aiming at a record performance at three or six miles (5,000 or 10,000 metres) might run one lap (¼ mile) at racing speed and follow it by three or four laps at a slower speed. This training might be continued for two or three hours, while the athlete runs about twenty miles.

To some extent the athlete, already possessing ability, improves in strength, endurance and skill by repetition in training of a standard performance at intervals long enough to avoid fatigue. But attempts have been made to strengthen specific muscle groups by special training, and Mr. G. T. Adamson (University of Leeds) touched on this subject when he described experiments on undergraduates in which the limit of each individual's capacity to perform certain movements—for example, the number of times a beam could be 'chinned'—has been determined. The subject then makes a circuit, which contains a number of these tests, in a given time and performs each one a certain proportion—say a half or a third—of his maximum. Periodic testing showed significant improvement in performance, both for strength and endurance, and the training rate was altered accordingly. This method of training differs from that usually followed by an athlete because the amount of work prescribed for training is quantitatively adjusted to the previously assessed capacity of the subject.

Two papers on animal training emphasized a theme already raised by Mr. Bannister in discussing the physical build of athletes: runners are bred rather than made. The training of the track-racing greyhound was described by Mr. J. K. Bateman (Greyhound Racing Association) in a paper read by Prof. E. C. Amoroso. Great attention is paid to the diet of the puppy to ensure proper skeletal and muscular growth, and from about three months old he is given plenty of opportunity for free exercise. Even a short period off his legs during the phase of rapid growth is likely to prevent a puppy from becoming a satisfactory racing dog. When about a year old, running training begins, and the galloping distance is gradually increased until the puppy can run at full speed for about 250 yards. Regular work and good feeding are continued on a progressive scale, but the distance over which the dog runs at full speed is only gradually increased, and he will only do this occasionally. Even when the dog is fully trained and in racing trim for races of 500–700 yards, a full-speed run over a distance is only done two or three times a week.

Each day when in racing trim the dog, apart from a period of about fifteen minutes self-exercise, has a walk of about two miles at a slow trotting pace. It was interesting to hear how much less training work is undertaken by canine sprinters as compared with the corresponding human athlete. When endurance is required, as in the coursing greyhound, a great deal more road walking is undertaken. The dog does not control his speed. He will always go all out at the beginning of a race, and his speed diminishes as he tires, unless some slight break, as in coursing or hunting, gives opportunity for recovery. A horse can undertake long-distance races because he is controlled by the jockey, and his energy output can be spread over a period.

The importance of breeding in the production of the successful racehorse was stressed in a paper by Mr. J. L. Jarvis, the Newmarket trainer, read by Mr. W. C. Miller (Equine Research Station, Newmarket). Almost all the winners of classic races can be traced back in their pedigree to some great race mare. Mr. Jarvis outlined the sequence of training a horse for the Derby, where a combination of speed and endurance is required. Training begins with the breaking in of the horse as a yearling, and he is regularly exercised for about an hour and a half each day during his first season. The next year, in the spring, he will first be given some trotting exercise on the roads, and then steady cantering exercise which is gradually increased in pace and distance. The prime aim of this training is said to be the building up of the muscles; but at the same time the resources of the circulation are increased so that the animal is able to meet the increased capabilities of the muscle with better supplies of oxygen. Training occupies about an hour and a half each day, unless the horse is being trained for distance races, when it will be longer. Unlike the human athlete, running over even shortish distances at a likely racing pace does not seem to be part of the technique of horse-training. The way in which a race is actually run—the initial pace, the running for position—depends upon the jockey and not upon the horse's judgment of pace. Training is an art, declared Mr. Jarvis, and a training routine must be suited to the mental and physical constitution of each particular animal.

Finally, Mr. J. Lynas (Blackpool Football Club) and Mr. J. Egan (Leigh Football Club), two well-known trainers and coaches of professional footballers, Association and Rugby League respectively, gave accounts of their methods of training. They made it clear that a general fitness for endurance and ability to run quickly on occasion makes only a foundation on which the particular skills of the game can be imposed. Mr. Egan analysed the duties of the different players in a team, showing, for example, how the physical and physiological requirements of a wing three-quarter in Rugby football differ from those of a forward and pointing out that, although an all-out run of fifty yards is usually a maximum, very few players are likely to undertake it; frequently, very rapid acceleration over a few yards is more important than first-class sprinting ability. Initial training at the beginning of the season concentrates on distance running to promote endurance, and more specific practice in sprinting, kicking and ball-handling is taken according to individual requirements. While Mr. Lynas seemed less inclined to regard an Association football team as a collection of specialists, his training requirements seemed to be on similar lines, with emphasis on the practice of the skills required for the game. Both trainers regarded speed in running as unimportant in itself. Many great players have been relatively slow runners, but their knowledge of the game and anticipation has often given them actually several yards start of their opponents.

One point which emerged clearly from the papers and from the discussion was that the term 'fitness' should be applied only towards a specific end. A certain degree of muscular development and ability, through the circulation, to transport oxygen is necessary for any sustained muscular activity—this might be termed a 'general fitness'. But beyond this there must be a 'specific fitness' involving the development of particular muscles and the acquirement and use of particular skills, such as pace judgment and economy of effort for the athlete, game technique for the football player and control of the horse by the jockey.

OBITUARIES

Dr. Winifred Brenchley, O.B.E.

DR. WINIFRED BRENCHLEY, the well-known agricultural botanist of the Rothamsted Experimental Station, died at her home at Harpenden, on October 27, after a long and crippling illness which, however, was mercifully without great pain for her. She was born on August 10, 1883; her father was a popular and successful schoolmaster at Camberwell, serving at one time as mayor of the Borough. In early childhood, while recovering from measles, a well-intentioned friend took her out for a drive: she caught a chill which so gravely injured her ears that she suffered all her life from deafness. But she never allowed this to interfere with her work or her social activities or with her never-failing helpfulness to her younger colleagues.

From James Allen's School, Dulwich, she went first to the Swanley Horticultural College, and then to University College, London, to study under F. W. Oliver, with whom there grew up a life-long friendship. In 1906 she went to Rothamsted, the first of the staff that A. D. Hall was then assembling, and the first woman scientist to be appointed, either there or at any other agricultural institution in the country.

She soon started investigations on plants by the water culture method which she, and afterwards her colleague Katherine Warington, developed into an instrument of remarkable effectiveness. From the outset she included metallic salts known to be toxic at high concentrations, and watched for the stimulus they were supposed to exert at low concentrations: spectrographic methods had not yet arrived, and she narrowly missed discovering the essential role of the trace elements. The earlier results are summarized in "Inorganic Plant Poisons and Stimulants", published in 1914 by the Cambridge University Press; a later revised and enlarged edition came out in 1927. The work continued, however, during all her time at Rothamsted: the last element dealt with was molybdenum.

Through Oliver's influence, Dr. Brenchley began a second group of investigations: ecological studies of the complex floras of farmed land. The effects of fertilizers in altering the competition-equilibrium between the various species in a meadow were described first in "The Manuring of Grassland for Hay" (Longmans) in 1924: but she was still continuing the work when she retired. Her studies of weeds in arable crops and grassland were brought together in "The Weeds of Farmland" (Longmans, 1920), extended later to include studies of the viability of weed seeds in the soil: she was able to show that some had remarkable powers of survival for many years. She also studied the effects on the growing plant of individual factors that make up the natural environment, especially temperature, light and nutrients. These botanical studies did not exhaust her scientific interests; she and Dr. A. D. Imms, then the Rothamsted entomologist, became great friends, and with his help she acquired considerable knowledge of insects.

Dr. Brenchley summarized the first thirty years of her work in the Rothamsted Annual Report for 1935, and the next ten years in the issue for 1939–45. She retired in September 1948, intending to write up her accumulated observations. These had been made with great care and deserved closer study than her busy working life had allowed; but her illness intervened, and it steadily grew worse to the deep regret of a wide circle of friends at Rothamsted and far beyond. E. JOHN RUSSELL

Dr. Wendell C. Bennett

WENDELL C. BENNETT, a distinguished student of Peruvian archæology, died on September 6 in his forty-eighth year. His end, while swimming off the shore of Martha's Vineyard in Massachusetts, was a tragic one.

At the time of his death, Bennett occupied a number of important posts at Yale University, where he was a professor of anthropology, a fellow of Pierson College, a research associate of the Peabody Museum and chairman of the Department of Anthropology. These were a few of the academic evidences of a highly successful career, which had been remarkably steady in its progress and exceptionally fruitful both in scholarship and in personal influence.

Almost from the first, Bennett had devoted himself to the pre-history of South America. With the exception of two early apprentice essays, one on the culture of the Tarahumara of northern Mexico and the other on the archæology of the Hawaiian Islands, his research was directed almost exclusively to South American archæology. His first undertakings in this area were begun while on the staff of the American Museum of Natural History, where he remained for seven years. These were rewarding years, during which he laid the groundwork of his own subsequent researches which very largely were responsible in establishing Peruvian archæology on the sound footing it now occupies.

It was during this period that he made the first stratigraphic excavations in Bolivia, working at the famous site of Tiahuanaco. For this fundamental work he was decorated afterwards by the Bolivian Government. While still at the American Museum of Natural History he carried out significant excavations in the north coastal area of Peru and in Venezuela. The former led to a re-definition of the chronological sequences of Peruvian archæology and the latter provided the first systematic archæological data for Venezuela.

On leaving the American Museum of Natural History in 1938, he moved to the University of Wisconsin, attracted there by the opportunity to teach. In 1940 he was invited to Yale, where he remained until his death. During his association with Yale, Bennett was able, despite his teaching and administrative duties, to continue his archæological research. One of his outstanding achievements in this period of his career was the part he played in organizing the Virú Valley project. Out of this large co-operative venture came his fine study of the Gallinazo culture. The last archæological enterprise on which Bennett was engaged is not yet published, but it is in the press and is concerned with the problem of the development of coastal Tiahuanaco culture.

The confidence of his fellow anthropologists that Bennett enjoyed and his reputation for sound counsel were reflected in the numerous posts to which he was elected and appointed in professional societies and organizations. He was president of the American Anthropological Association in 1952, and executive secretary of the Joint Committee on Latin American Studies from 1942 to 1944. He was chairman of Yale's Area Studies Executive Committee, and he was active in the Social Science Research Council.

Wendell Bennett was born in the Middle West—in Marion, Indiana—on August 17, 1905, the son of William Rainey Bennett, a minister and lecturer. His schooling was in Chicago and his university career at the University of Chicago, where he was an excellent scholar as well as an exceptional athlete. In 1925 he married Hope Ranslow and from this marriage two daughters, Lucy and Martha, were born. As a person Bennett possessed great charm and warmth. He had a fine gift for friendship to which all varieties of people responded. It was, in fact, this lovable quality which contributed so greatly to his success in organizing. As an archæologist he was rigorous and critical, demanding the highest standards of professional competence from himself and from his colleagues. His contributions have been fundamental in advancing our knowledge of South American prehistory.

He will be mourned by a wide circle of friends and colleagues for the feeling of personal loss that the departure of a generous spirit always leaves, and for the sense of loss that the interruption of a full career always implies. HARRY L. SHAPIRO

Prof. N. D. Zelinskii

NICHOLAS DIMITRIVICH ZELINSKII was born on February 6, 1861, in Tiraspol in the Province of Kherson. He received his school training locally and in Odessa, and afterwards went to the University of Novorossisk. Later he studied in Leipzig and in Göttingen, working there in the laboratory of Victor Meyer. In 1888 he obtained his master's degree and was appointed lecturer at his old University of Novorossisk. There he presented first his master's thesis dealing with thiophene chemistry in 1889, and two years later a thesis for his doctorate on the stereoisomers of saturated carbon compounds.

Zelinskii was appointed adjunct professor in Moscow in 1893 and, except for six years spent at St. Petersburg, remained there until his death on July 31 of this year. The six years interruption occurred during 1911–17, when in company with a hundred other professors and teachers he resigned as a protest against the dismissal of the entire administration staff of the University of Moscow by the Ministry of Education.

Although Zelinskii's contributions to chemical knowledge ranged over a vast field, including heterocyclic derivatives, protein hydrolysis and the synthesis of α-amino-acids, his chief contributions were to hydrocarbon chemistry. In 1891 he prepared the first synthetic naphthene, 1.3-dimethyl*cyclo*hexane, and showed its close relationship with the octanaphthene of Caucasian petroleum. This, and later work on the synthesis of saturated cyclic hydrocarbons, ranging from simple to complex polycyclic systems, brought with it an interest in petroleum and the terpenes. As early as the 'nineties he took an active part in the operation of a plant to prepare aromatic hydrocarbons by pyrolysis of petroleum, and thus was among the earliest pioneers of petrochemicals. Later, he showed that aromatics could be more conveniently produced from petroleum by catalytic dehydrogenation of naphthenes than by pyrolysis. This resulted from his discovery in 1911 that *cyclo*hexane derivatives can be converted to aromatic hydrocarbons by passage over a suitable catalyst, an observation which led to the establishment of a school of contact catalysis under his leadership. His contributions in this field were immense; he was the first to use platinum metals as hydrogenation/dehydrogenation catalysts and to differentiate between C_5- and C_6-naphthenes by their behaviour on dehydrogenation—a valuable tool in his investigation of the composition of petroleum. Isomerization, desulphurization, cyclization and many other processes of technical interest owe much to his pioneer efforts. His interests included also the origin of petroleum, where no doubt his early association, in 1889, with an expedition to the Black Sea, which proved the bacterial origin of the hydrogen sulphides present in its depths, encouraged his views as to the organic origin of petroleum, views which he supported with experimental work on the thermal decomposition of sapropelite, a substance of algal origin deposited in vast quantities on the shores of Lake Balkhash.

Zelinskii's first paper appeared in the *Journal of the Russian Chemical Society* when he was a student in 1884, and in the sixty-seven years that followed he published more than five hundred others, including many with some hundred and forty of his students. On three occasions he was awarded the highest honour of the U.S.S.R.—the Order of Lenin. He also received numerous other honours from the government of the U.S.S.R., including the title of Hero of Socialist Labour.

S. F. BIRCH

WE regret to announce the following deaths:

Dr. W. R. Cunningham, librarian of the University of Glasgow and keeper of the Hunterian books and manuscripts, on October 25, aged sixty-three.

Prof. Colin G. Fink, recently head of the Division of Electrochemistry, Columbia University, and president in 1917 of the Electrochemical Society in the United States, aged seventy-two.

Mr. H. J. Hornby, chairman of A. Gallenkamp and Co., Ltd., and chairman during 1941–43 of the British Laboratory Ware Association, Ltd., on November 2, aged sixty-eight.

Prof. E. Piwowarsky, professor of general metallurgy and director of the Institute for General Metallurgy and Foundry-work in the Technical High School, Aachen, aged sixty-one.

NEWS and VIEWS

Nobel Prize for Physics for 1953: Prof. F. Zernike

THE work of Prof. F. Zernike, who has been awarded the Nobel Prize for Physics for 1953, includes many distinguished contributions in fields other than optics, but his successes in this branch of physics alone have been sufficient to earn him an international reputation. His serious interest in optics seems to have started some twenty years ago. In 1934 he published a diffraction theory of the Foucault knife-edge test for the figure of astronomical telescope mirrors. This work was notable on two counts: for the discovery of the so-called circle polynomials (now widely, and rightly, known as Zernike polynomials), and for the introduction of the method of phase contrast. Almost immediately Zernike realized that the same method could be used in the other extreme of optical instruments, namely, the microscope. The fruitful results of this invention, especially in biological work, are both sufficiently widely known and appreciated to require no comment. This being so, it is easy to forget Prof. Zernike's other contributions to optics. His work, and that of his pupils, on the diffraction theory of aberrations, the experimental study of these effects, the use of the method of the 'coherent background' in diffraction, and the theory of partial coherence, equally constitute an outstanding contribution to our present knowledge of optics. Prof. Zernike is well known in Britain. He has delivered the Thomas Young Oration of the Physical Society, and in 1952 he was awarded the Rumford Medal of the Royal Society.

Royal Society: Award of Royal Medals

H.M. THE QUEEN has been graciously pleased to approve recommendations made by the Council of the Royal Society for the award of the two Royal Medals for 1953 as follows: to Sir Paul Fildes, O.B.E., F.R.S., for his classical researches on growth factors for bacteria and for laying the foundation of work leading to a rational approach to chemotherapy; to Prof. N. F. Mott, F.R.S., for his eminent work in the field of quantum theory and particularly in the theory of metals.

Metrology at the National Physical Laboratory, Teddington: Mr. F. H. Rolt, O.B.E.

MR. F. H. ROLT, who has retired from his post as the superintendent of the Metrology Division of the National Physical Laboratory, Teddington, has been associated since 1912 with the laboratory's work in the field of engineering metrology and standardization. During the First World War the widespread application by the Ministry of Munitions of the principles of interchangeable manufacture placed enormous demands upon the Laboratory for verifications of reference standards and gauges, and for the development of methods and apparatus for the precise measurement of dimension and shape. Appreciation of the economic advantages of quantity production gave rise later on to studies in the Metrology Division of the basic principles underlying suitable design of interchangeable components and the efficient control of such products by accurate gauging or measurement during manufacture. Mr. Rolt was responsible for the prosecution of many of these studies, and for several developments of methods and apparatus now widely adopted in the practice of engineering inspection. His "Gauges and Fine Measurements", published in two volumes in 1929, achieved world-wide renown and appreciation. In 1941 he was seconded to the Ministry of Supply (Machine Tool Control), in which he served until the end of the Second World War, first as director of gauges and measuring instruments and later as director of jigs, tools and gauges. For these services he was made O.B.E. He succeeded Mr. J. E. Sears as superintendent of the Metrology Division in 1946. Mr. Rolt has contributed much to the work of numerous committees of the British Standards Institution and of other organizations, both national and international, concerned with the establishment of engineering standards. He took a leading part in the post-war American–British–Canadian conferences, one of which led to the adoption of the unified screw thread. He is also keenly interested in the education of engineering students and apprentices, and was instrumental in introducing engineering metrology as a subject for the Higher National Certificates in mechanical and production engineering.

Dr. H. Barrell

MR. ROLT is being succeeded by Dr. H. Barrell. Dr. Barrell was educated at the Royal Grammar School, High Wycombe, and the Royal College of Science, London, where he studied physics and later specialized in spectroscopy. He joined the staff of the National Physical Laboratory in 1923, and was associated with Mr. Sears, of the Metrology Division, in determinations of the metre and the yard in wave-lengths of light, and of the refractive index and dispersion of air. In recent years he has had charge of research work in the Division into optical and microwave interferometry, directed towards improving the precision of length measurements, and he has published many papers on this subject, particularly since the War. Though his work has been chiefly on the physical side of the Metrology Division, Dr. Barrell has had considerable experience of engineering metrology, especially since 1939. During the War he successfully adapted the pneumatic gauging principle in machines for simultaneous multiple inspection of several dimensions on certain types of ammunition, and this principle was later applied by him to the measurement of variations from uniformity of wool and cotton between the carding and spinning operations.

Department of Ethnography, British Museum:
Mr. H. J. Braunholtz, C.B.E.

Mr. H. J. Braunholtz retired from the keepership of the Department of Ethnography in the British Museum, London, on October 12. A member of St. John's College, Cambridge, Mr. Braunholtz studied classics and modern languages, graduating in 1911, and became an assistant keeper in the British Museum in 1913 under the late Captain T. A. Joyce, who was head of the Ethnographical Section of the Department of Oriental Antiquities and Ethnography. In 1938 Mr. Braunholtz was appointed keeper of the Department, and, when ethnography was made a separate department in 1945, he became its first keeper, so that, apart from the period of the First World War when he served in the R.A.M.C., practically the whole of his working life has so far been devoted to the Museum. When he entered the Museum, the staff was very small, and he was responsible for the registration of material from the whole field covered by his Department. A conscientious and exact scholar, he made the most of his opportunities and developed an extremely wide and detailed knowledge of the vast ethnographical collections of the Museum, and through them of the customs and habits of their makers. The collections include particularly fine series of objects from the ancient civilizations of Central and South America, a subject particularly dear to the heart of his old chief, Joyce, and Mr. Braunholtz followed him in making this a special interest. Apart from ancient America, he gave particular attention to the Pacific and Africa south of the Sahara, and his knowledge was deepened by field trips to East and South Africa, where he did not confine himself to the work of modern peoples but also made on his own account a large and well-documented collection of stone implements, which he afterwards gave to the Museum. A later visit to West Africa on behalf of the Colonial Office resulted in recommendations which led to action to preserve examples of the art and material culture of the peoples of the West African Colonies, including the establishment of museums. Another result of his trip was that the 'Oni of Ife kindly allowed his famous series of bronze heads to be taken to England for treatment and temporary exhibition in the Museum. Outside the Museum, Mr. Braunholtz has rendered conspicuous service to the Royal Anthropological Institute as a member of the council, honorary editor and president for two terms. He was made C.B.E. in 1951.

Mr. A. Digby

Mr. Braunholtz is succeeded as keeper by Mr. Adrian Digby, who graduated from Brazenose College, Oxford, where he also obtained the diploma in anthropology. Mr. Digby entered the Museum as an assistant keeper in 1932 and was appointed deputy keeper of the Department of Ethnography shortly after the end of the Second World War. During the War he worked for Naval Intelligence and was for a time attached to the Hydrographic Department of the Admiralty. The areas which have claimed most of his attention are Oceania and America, and he specializes in the archæology of Central America. He is also particularly interested in various aspects of technology, including sailing and navigation, of which he has practical experience. After representing the Museum at the Twenty-ninth International Congress of Americanists, held in New York in 1949, Mr. Digby made a tour of museums in the United States in order to study methods of display and other museum techniques. When the Ethnographical Gallery of the British Museum was reorganized after the War, his exhibits of American archæology and ethnology pointed the way to the arrangement of the whole gallery.

Atomic Energy in Great Britain

The White Paper on the future organization of the United Kingdom Atomic Energy Project (Cmd. 8986; pp. 10; London: H.M.S.O., 1953; 6*d*. net) summarizes the main recommendations of the Committee set up last April, with Lord Waverley as chairman, "to devise a plan for transferring responsibility for atomic energy from the Ministry of Supply to a non-Departmental organization and to work out the most suitable form for the new organization, due regard being paid to any constitutive and financial implications". These recommendations have been accepted by the Government, although the report itself will not be published in full because it deals with many matters which, for reasons of security, cannot be disclosed. They include the establishment of an Atomic Energy Corporation, as a statutory corporation, with an executive board and carrying the responsibility for the establishments at present controlled by the Atomic Energy Research Establishment, by the Production Division of the Ministry of Supply and by the Atomic Weapons Research Establishment, although the Ministry of Supply will retain responsibility for the conventional components of atomic weapons. The Waverley Committee suggested that the Lord President of the Council was the most suitable Minister, of high Cabinet rank and with no departmental responsibilities encroaching on the field of atomic energy, to be designated as responsible to Parliament for monies provided for the Corporation and for policy directions given to the Corporation, and this suggestion has been adopted by the Government. The Lord President of the Council will also be chairman of the Ministerial Committee, representative of all Ministerial Departments concerned with various aspects of atomic energy. The Ministry of Defence will remain generally responsible for the allocation of resources available for defence purposes between atomic weapons and conventional arms, and for the distribution of effort between the research, development and production of atomic weapons.

Administrative preparations for giving effect to the Committee's recommendations are being made.

An Order in Council transferring responsibility for atomic energy from the Minister of Supply to the Lord President of the Council as from January 1, 1954, will be laid before Parliament, and later a Bill will be introduced to provide for setting up the Corporation. It is proposed that the chairman of the Board of the Corporation will act as general manager, and the Board will include four whole-time functional directors: for engineering and production; for weapons; for research; and for administration and finance. Two part-time members with no separate technical function are also proposed. It is emphasized that salaries offered by the Corporation should not be seriously out of scale with those paid by other public corporations, and it is suggested that the staff of the atomic energy undertakings should be seconded to the Corporation at the vesting date for an initial period which might extend to two years, during which they would retain their Civil Service status unimpaired. Before the end of this period, the Corporation would be expected to offer individuals employment on appropriate terms which they would be free to accept or decline. Security would be primarily the responsibility of the Corporation, subject to the right of the designated Minister to satisfy himself as to the working of the arrangements. The White Paper stresses two points in conclusion: first, overall policy will remain firmly in the hands of Government, and objectives and policy will be determined by Government directives; second, the rights and interests of existing staff will be fully respected, and consultation with staff representatives will take place at the appropriate time.

New Publications Facilities of the Chemical Society

The Chemical Society has recently announced plans for two new services to be available from next January to Fellows of the Society and others. The Society is to commence the publication, under the title of *Current Chemical Papers*, a monthly world list of new papers in pure chemistry. The entries will include titles of papers (expanded where necessary), the authors' names and the references to the original journal, and will be classified into the principal branches of chemistry under some twenty different headings. This publication is not intended to become a substitute for an abstracting service, but it is designed to advise research workers of newly published papers more rapidly than would be possible in a journal publishing full abstracts. There will be no index. The price for Fellows will be 25*s*. a year (as part of their publications allowance), and for outside subscribers it will be £2 10*s*. a year. The second scheme which the Society has introduced is that offprints will be made available of individual papers published in its *Journal*. The *Proceedings* of the Society (which is issued free each month with the *Journal*) will contain lists of papers which have been accepted for publication and will normally be published in the *Journal* during the succeeding two months. Thus, by ordering the reprint promptly, it will be possible to obtain it at about the same time as publication. Fellows are invited to pay 30*s*. (as part of their publications allowance) for one book of thirty vouchers, valid for one year only, each of which can be exchanged for one reprint of any paper selected from the *Journal*. Additional vouchers (valid for three years) are available outside the publications allowance for Fellows and also for libraries and other subscribers to the *Journal* at 10*s*. per book of five vouchers. Single reprints can also be purchased by any applicant at 5*s*. per reprint.

Library Classification of Zoology Books

A communication from Prof. R. Denison Purchon, Raffles professor of zoology, University of Malaya, Singapore, where the Library of Congress Classification has been adopted in the new Library which has recently been built, directs attention to certain features of the Zoology Section of that Classification which urgently need revision. He points out that a small library may work efficiently by a classification of books according to their location on the shelves; but in a larger library it is desirable to retain flexibility of expansion, and to gain the maximum assistance from the experience of other libraries, by adopting one or other of the main systems in use. It is recognized that the purpose of a library classification is to enable the student to find a book with ease, by reference to catalogues. It must be borne in mind, however, that many university students, receiving little or no instruction on the proper use of a library catalogue, prefer to search for their books on the shelves rather than in the catalogues. Such browsing has definite advantages to the student though it may be undesirable from the librarian's point of view; but it does indicate the need for a logical arrangement of books on the shelves. The Library of Congress Classification is partly systematic, and partly alphabetical. An alphabetical treatment is suitable for minor details; but Prof. Purchon directs attention to the confusion arising when it is applied to a super-phylum such as the "Vermes", and to the undesirability of mixing the phyla and their sub-divisions alphabetically. The treatment of the Insecta is also criticized, and the placing of the Prochordata in the Vertebrata. The sub-divisions of the sections on botany and zoology do not provide the expected sub-sections for animal physiology, animal ecology, evolution of animals, and genetics in the zoology section. References to physiology are scattered systematically; but it is a matter of opinion whether physiological work should be in an appropriate systematic position or collected. Prof. Purchon also points out that work on animal ecology warrants the inclusion of the headings 'terrestrial', 'fresh water' and 'marine', and criticizes the omission of headings for the evolution of animals, and for animal genetics.

Research Essay Competition

A criticism that is often voiced with regard to technical development in Great Britain is that many new ideas which originated in British laboratories were not followed up at the time and were later exploited in other countries. One of the difficulties in the way of further advance is the gulf between the industrial scientist and the essentially non-technical board of directors of the firm which he serves. First, industrial scientists are often not able to describe their work and its potential applications in simple concise terms; secondly, they do not often appreciate the relationship of their own work to the broad economic purpose of their firm. As a contribution in overcoming these difficulties, the scientific advisory board of the journal *Research* is sponsoring an essay competition for which prizes of £100 and £50 will be offered, with a special prize for the best entry from a competitor less than thirty years of age.

Entrants will be required to submit an essay describing any recent advance in science (whether their own work or the published work of others) and discussing the potential applications and industrial development of the work; it should be emphasized that the word 'industrial' is to be read in the broadest sense, including such fields as agriculture, etc. Proof will have to be given that the entrant was actively engaged in scientific research during the period November 1, 1953–June 30, 1954. Essays must be submitted by June 30, 1954. Joint entries by not more than two competitors may be submitted. Further details of the competition can be obtained from *Research*, Butterworths Publications, Ltd., 88 Kingsway, London, W.C.2.

Since these prize offers were announced, the *Sunday Times* has offered two further prizes of £100 and £50 for the two best entries considered by the Editor, in consultation with the Advisory Board of *Research*, suitable for publication in a general newspaper and dealing with certain set topics. Further information can be obtained from either *Research* or the *Sunday Times*.

B.C.G. Vaccination of School Children

A circular dealing with the vaccination of school children with B.C.G. vaccine has recently been sent to local health authorities by the Ministry of Health. The circular refers to a previous one, and it was after the issue of this latter document that the Minister of Health approved proposals by the local health authorities to enable B.C.G. vaccination to be given to persons known to have been in contact with tuberculous infection. The present circular states that the Minister is now ready to approve the offer of B.C.G. vaccination to school children during and, if possible, towards the end of the year preceding their fourteenth birthday. This extension of the vaccination to school children should not, however, prejudice the scheme for the vaccination of contacts, which should continue. The local health authority will decide, after consultation with the local education authority, whether to extend this vaccination to the school children specified. For their guidance a medical memorandum which has been issued by the Ministry (No. 324 BCG) and discusses the value of B.C.G. vaccination and the techniques to be used by vaccinators, is being sent direct to medical officers of health. The circular states that vaccination should be carried out by designated medical officers on the responsibility of the medical officer of health after consultation with the school medical officer. Most of the vaccinations will be done during the child's penultimate year at school, so that it will be possible to follow up each vaccinated child for at least a year. Children who stay at school after the age of fifteen should also be vaccinated not later than their fourteenth year. The consent of the parents must be obtained before vaccination is done. If the parents are anxious about the vaccinated arm, they may consult the school medical officer or the chest physician, who will consult the family doctor. Talks and discussions are suggested to eliminate fear or misunderstanding of the vaccination. Before the vaccination scheme is extended in the manner just described, local authorities are asked to give the Minister of Health an outline of the way in which they propose to extend the scheme and a statement of the areas to be covered and the measures to be taken for the tracing and vaccination of contacts.

Scottish Marine Biological Association: Millport Laboratory

On November 11 the reconstructed public aquarium at the Scottish Marine Biological Association's Millport Laboratory was opened by Dr. J. R. Peddie, secretary and treasurer of the Carnegie Trust for the Universities of Scotland. The original aquarium, constructed in 1904, had served the dual purpose of a public aquarium and tank room for research. It had long been out of date, and three years ago was closed to the public. The Carnegie Trust for the Universities of Scotland had previously made a grant of £600 a year for five years to cover the construction of a new public aquarium. This has now been achieved, while a separate tank room and aquarium is provided for the use of the scientific workers. The general plan of the public aquarium is the work of Mr. E. Ford, director of the Laboratory, while the internal design of rock is that of Dr. R. B. Pike, principal scientific officer at Millport. A large number of people representing numerous bodies interested in all aspects of the work at Millport attended the opening ceremony, at which the chair was taken by the president, Prof. C. M. Yonge. It is interesting to note that this newest of all public marine aquaria was opened one hundred years after the first such aquarium, due to the enthusiasm of Philip Henry Gosse, was opened, on May 21, 1853, in the Zoological Gardens, London.

The British Trust for Ornithology

In addition to twenty-first birthday greetings from many distinguished ornithologists from Great Britain and countries overseas, members of the British Trust for Ornithology should welcome the news from the honorary treasurer that the satisfactory financial position will enable the Trust to extend its inquiries. This is referred to in the report for 1952, which shows that the Trust's membership is continuing to grow. The report contains a valuable statement by Dr. David Lack, director of the Edward Grey Institute, describing the Trust's part in the launching of the Institute and their present relationship. Work undertaken on behalf of the Trust is also referred to and shows that, in 1952, more heronries were reported than in 1951 and that about 1,500 more nest records were recorded in 1952 than in 1951. The sample census of great crested grebes has been continued, and shows that in 1951 a record total of adult birds was observed. The black redstart inquiry was continued, and confirmed that thirty-one pairs of these birds bred in England in 1951, while seven more pairs were present but not proved to breed. For the first time on record singing males occupied territories in Scotland. Investigations have also been made into the birds of high-level woodlands, the breeding distribution and habitats of the pied flycatcher, and the wintering of gulls in Britain. Details of the ringing scheme show that more than ten thousand more birds were ringed in 1952 than in 1951. The report also contains an account of the work of the Edward Grey Institute during April 1952–April 1953.

Documentation in Aeronautics Research

At the second meeting in London during September 3–4 of the Documentation Committee of the Advisory Group for Aeronautical Research and Development of the North Atlantic Treaty Organization, it was decided that the activities of the Committee should be given the fullest possible publicity in the aeronautical field. The aims and work of the Documentation Committee are related to and conditioned by the aeronautical information activities of governments, industrial organizations, research institutes and technical associations, and it was resolved accordingly that the proceedings of the Committee should be made available to all interested agencies in each country. Inquiries regarding, or comments on, the work of the Committee should be sent to the Chief Information Officer, Royal Aircraft Establishment, South Farnborough, Hants. The agenda of the first two meetings included such items as standardization of the size and format of documents, the provision of catalogue cards with reports, the improvement of existing abstracting services, particularly in respect of coverage and elimination of duplicate effort, and research into documentation. Proposals for the classification of aeronautical literature were considered, including the development of the aeronautical sections of the Universal Decimal Classification and trial of the scheme by the Nationaal Luchtvaart Laboratorium (Holland) for cataloguing aerodynamic data; and the United Kingdom delegates indicated that careful experiment will be made both into the use of the cards thus provided and into the problems involved in producing similar cards for security-graded classified reports issued in the United Kingdom. The production of an up-to-date aeronautical interlingual dictionary in English, French, German, Italian, Russian and Spanish, based on the British Standards Institution's glossary of aeronautical terms, was also discussed.

Pleistocene Correlation and Nomenclature

At the Fourth Congress of the International Association on Quaternary Research, held in Rome and Pisa during August–September, the following committee was appointed to consider regional and world-wide problems of Pleistocene correlation and nomenclature: *Chairman*, Prof. I. M. van der Vlerk (Leyden); *Secretary*, Prof. E. Tongiorgi (Pisa); Prof. C. Arambourg (Paris), Prof. R. F. Flint (Yale), Dr. K. P. Oakley (London) and Prof. P. Woldstedt (Bonn). The committee will be assisted by a number of corresponding members. Its first task will be to collect the views of specialists in different parts of the world on the question of the subdivision of the Pleistocene. The secretary (at Via Luca Ghini 2, Pisa) would be glad to receive any relevant suggestions.

The Free University of Berlin

An article in *Science* (118; 1953) by Prof. W. O. L. Heubner, of the Free University of Berlin, gives a first-hand account of events in the University of Berlin while under Nazi and, later, Communist control. Under Russian control it became clear that the University of Berlin would not be tolerated as an institution of higher learning for its own sake; it was used as a means of educating 'specialists' who would serve the advancement of the 'working' people, subjects like religion, law, history, Greek and Latin becoming superfluous. Student organizations were controlled by indoctrinated pro-Communist enthusiasts. Prof. Heubner also describes how the Free University of Berlin came into being in 1948.

Mineralogical Society: Officers for 1953–54

The following have been elected officers of the Mineralogical Society for 1953–54: *President*, Dr. J. Phemister; *Vice-Presidents*, Dr. F. A. Bannister and Dr. F. Dixey; *Treasurer*, Prof. J. H. Taylor; *General Secretary*, Dr. G. F. Claringbull (c/o Geological Society, Burlington House, Piccadilly, London, W.1); *Foreign Secretary*, Dr. L. J. Spencer; *Editor of the Journal*, Dr. L. J. Spencer.

Announcements

Dr. S. J. Folley, head of the Physiology Department of the National Institute for Research in Dairying, Reading, has been appointed a visiting professor in the Collège de France, Paris, for the month of December. He will deliver a course of six lectures on "La Physiologie et la Biochimie de la Sécrétion lactée".

Dr. W. Roman has been appointed head of the Division of Biochemistry at the Institute of Medical and Veterinary Science in Adelaide, South Australia; he will carry out research on metabolic problems in co-operation with the medical and veterinary professions. He will continue to edit *Enzymologia*.

The Wellcome Research Library of the Royal Society of Medicine will be opened officially by the Marquess of Salisbury, the Lord President of the Council, at 2.30 p.m. on December 4, 1953, in the Barnes Hall. Admission will be by ticket, obtainable from the Assistant Secretary of the Society.

The first Middleton Memorial Lecture, organized by the Trustees of the Sir Thomas Middleton Memorial Trust, will be delivered by Sir James Scott Watson in the Senate House of the University of London on December 10 at 5.30. The title of Sir James's lecture will be "The State and Agriculture (with special reference to Thomas Hudson Middleton's contribution to the development of agricultural education and research)". The chair will be taken by Dr. Norman C. Wright. The lecture is open to the public.

Under the auspices of the American Philosophical Society, Philadelphia, and the National Academy of Sciences, Washington, an effort is being made to bring together in book form all that is known of John Abbot's life and of his work as a student and delineator of American birds. Miss Elsa G. Allen, of the New York State College of Agriculture, Cornell University, Ithaca, New York, would be grateful for information which may help to throw light on the history of this remarkable man. Information as to the present whereabouts of any of his illustrations would also be welcomed.

The Société Chronométrique de France, with the support of the corresponding bodies in Belgium, Germany, Great Britain and Switzerland, is organizing an international congress of chronometry, to be held in Paris in the spring of 1954. The congress will not be restricted to horology but will cover all aspects of the measurement of time, including the determination of intervals of time and of the quantities derived from them, questions of frequency, speech, acceleration, etc. Those interested should write to Prof. R. Baillaud, president of the Société Chronométrique de France, director of the Observatoire National at Besançon, Doubs, from whom further details can be obtained.

Erratum. In the communication entitled "Influence of Cysteinamine, Methylamine and Cortisone on the Toxicity and Activity of Nitrogen Mustard", by Dr. O. Peczenik, in *Nature* of September 5, p. 454, par. 2, line 14, for "0·125 gm." read "0·125 mgm.".

BIOLOGICAL RHYTHMS

THE fourth conference of the International Society for the Study of Biological Rhythms took place at the University of Basle during September 18–19. One hundred and twenty-two participants from ten countries heard and discussed forty-two papers dealing with many aspects of biological periodicity.

Prof. F. Georgi, the able local organizer, opened the proceedings.

Following the philosophy of Klages, E. Frauchiger (Berne) indicated the important part which the concept of rhythm plays in the arts and sciences. Contrasting rhythm and beat (*Takt*), he defined the former as the "similar repetition of similar events". K. Wacholder (Rostock), reviewing the physiological field, also stressed the flexibility of biological rhythms, which is absent in many physical models and simple machinery. He discussed in considerable detail the different ways in which rhythmic activities may originate. F. Gerritzen (The Hague) considered biological rhythms as regular alterations of a continuous metabolic flow in an open system.

Mathematical methods for the measurement of period length were discussed by T. Bartels (Göttingen), who based his deliberations on formally similar geophysical and sunspot measurements. A. Sollberger (Stockholm) discussed certain statistical proceedings when testing biological data for the 24-hr. period, while G. Oberhoffer (Bonn) described a new optical method for the frequency analysis of graphs. T. Blume (Düsseldorf) claimed that an ingenious adaptation of Fourier analysis enables him to detect relevant periodic components from fairly short-time series of measurements. Clinical applications of this approach were reported by W. Menzel (Hamburg), who pointed out that disease is often accompanied by a loss of physiological rhythms, which are characteristic for many bodily functions (for example, temperature, sleep, renal function) during health. Thus rigidity of organ functions as well as more serious breakdowns are both signs of a decreased homeostasis. Recovery after illness (for example, from tuberculosis), as E. Dissmann (Klagenfurt) pointed out in the discussion, is frequently accompanied by the resumption of the physiological rhythms.

From the botanical field, which has always been leading in studies of biological periodicity, E. Bunning (Tubingen) reported in particular on the connexion which seems to exist between the long-known phenomena of diurnal leaf movements and of photoperiodicity. The effects of light and darkness on growth and flowering depend on the momentary adaptation of a plant of which its leaf position is yet another indication. This applies both to long- and short-day plants. A. Remane (Kiel) discussed some exogenous and endogenous factors which produce the great fluctuations in numbers, known to occur in arctic and in marine animals. He pointed to the complexity of such fluctuations and to their connexion with periodic migration and epidemics.

H. Kalmus (London) listed some examples of differential responses of genetically differing individuals of polymorphic species to time of day or season. Among the former he mentioned the colour variants of female *Colias* butterflies and among the latter the chromosomal races of *Drosophila pseudoobscura*. He also discussed the genetical implications of temporal isolation and of the cyclomorphosis of Rotifers and Cladocera. G. P. Wells (London) discussed the very regular changes of water in the tubes and burrows of sedentary polychaetes, which are unconnected with any environmental rhythms; he described ingenious techniques for their recording. O. Kohler (Freiburg) talked about the rhythmic activities in bird song and behaviour and on certain mechanisms in birds and bees which compensate for the daily movement of the sun and thus make navigation possible.

C. P. Richter (Baltimore) showed cycles of several weeks duration in the behaviour and physiology of rats, which occurred after thyroidectomy, during sulphamerazine treatment or after the application of radioactive iodine. Interference with the posterior lobe of the pituitary produced fourteen-day cycles, whereas removal of most of both ovaries often resulted in cycles of ninety days period length. Experiments concerning adrenal cycles of mice and of men were described by F. Halberg (Minneapolis), who then compared adrenal and sexual cycles. T. Staehelin (Basle) reported some success in treating certain rigidly rhythmical manifestations of schizophrenia by various means affecting the brain stem, which he considers to be the region responsible for many rhythmic activities.

H. Reimann and H. Zellweger (Beirut) directed attention to an alarming, if benign, condition, sometimes called 'periodic disease', which by its familial occurrence and by the fact that almost exclusively Armenians and Jews are affected seems to suggest some hereditary basis, but is otherwise of unknown etiology.

Some complexities of circulatory rhythms were discussed by E. Rothlin and A. Cerletti (Basle), while P. Vara (Helsinki) showed the first recorded ECG of an unborn human foetus. H. Mislin (Basle) demonstrated encephalograms of Cephalopods; G. K. Döring (Tübingen), E. von Philippsborn (Oberstdorf) and others discussed rhythm in respiration. T. Petrén (Stockholm) described fluctuations in the glycogen content of chick embryos.

Among the factors which influence biological rhythms, W. Frey (Berne) discussed observations and experiments concerning the influence of air ionization on the circulation, while several others discussed the interactions of hydrotherapeutic methods and sport activities with body rhythms.

Problems of the 24-hr. periodicity were attacked from many angles. T. N. Mills and S. W. Stanbury (Manchester) described diurnal variations in the excretion of various substances by the renal tubules. T. Aschoff (Heidelberg) discussed some methods by which external rhythms (for example, temperature, light, noise) can be shown experimentally to be in control of diurnal activities of organisms. A. Kilbinger (Essen) showed that one such factor—important in plant life—may be a greatly increased carbon dioxide content at night of the air above soil.

N. Kleitman and T. G. Engelmann (Chicago), in a description of the development of the sleep-wakefulness pattern, showed that, contrary to a widely held belief, the total duration of a baby's sleep does not change up to the twelfth week, but that the day fraction of sleep, which is the smaller from birth, decreases. During the succeeding fourteen weeks the duration of night sleep remains unchanged; but day sleep decreases further until an adjustment to the infant's environment is reached; this consists in one long unbroken period of night sleep and short morning and afternoon naps. H. R. Richter (Basle) stated that sleep and wakefulness, like youth and age, entail different brain rhythms, a fact which can be used for the investigation of sleep. A. W. Eiff (Bonn) succeeded, by altering the clock during a short period of anæsthesia, not only in deceiving the time-sense of people living in a constant-condition room, but also found a shift in certain diurnal body rhythms, though not in others. D. Lüderitz (Munster) showed that thyrotoxic and myxœdematous patients differ from healthy people in their resistance to sleep-disturbing noises. T. Mollerstrom and S. Svensson (Stockholm) described the diurnal rhythms of various types of diabetes and stressed the success of the adjustment of therapeutic measures to those rhythms. In a more general way this principle was supported by W. Menzel and A. Jores (Hamburg).

G. Metz and P. Andlauer (Strasbourg) reported that in certain selected industries fewer accidents occurred during night shifts than during day shifts, while A. Pierach (Nauheim) described the adverse effects of night work and of frequent changes of working hours, especially on diseased people.

It is hoped that—as was the case after the last conference—the papers and discussions of this conference will be published in a supplement to the *Acta Medica Scandinavica*. Profs. A. Jores and W. Menzel, of Hamburg (2. Medizinische Klinik), were elected president and secretary of the Society. A sub-committee on terminology was also elected. The next conference will be held in Stockholm in 1955.

H. KALMUS

ORGANO-PHOSPHORUS INSECTICIDES

A SYMPOSIUM on organo-phosphorus insecticides, arranged jointly by the Crop Protection Panel of the Society of Chemical Industry, the Association of Applied Biologists, the Biological Methods Group of the Society of Public Analysts and Other Analytical Chemists and the Pharmacological Society, was held at the Imperial College of Science and Technology, London, on the morning and afternoon of October 2. The meeting attracted a large audience, more than filling the large Chemistry Theatre of the College.

The large attendance may have owed more to the participation of four learned societies than to the choice of a topical subject which is much in the scientific news, because the open discussion was not as lively as one might have expected, only a small proportion of those present participating. Coming so soon after the much more active two-day discussion on "Anti-cholinesterases", organized by the British Pharmacological Society and the Society of Chemical Industry, which was held during March 27–28, one wonders whether the subject is not a little 'played out'. A more likely explanation, however, of the somewhat apathetic discussion may have arisen from the fact that so many societies were interested. One feels that their representatives on the joint committee may have been too polite to press their own interests, with the result that the five invited lecturers presented a rather incoherent display, and the audience was left wondering what were the most important arguments in which they were expected to participate.

There is unquestionable good in different societies coming together for such symposia, but it is more important than when they meet alone that the subject-matter should be selected and restricted, and a clear field of controversy mapped out. Granted this greater care of planning, which is clearly a more difficult task for an *ad hoc* joint committee, meetings of the most diverse societies can be very successful. Where this is lacking, there tends to be a diffidence on the part of the various contributors to discuss the particular aspects of the most interest to them in the presence of representatives of other professions, who they feel may not be particularly interested. It was this factor, I think, which tended to discourage the discussion on this occasion.

The morning session was devoted to toxicology: a paper prepared by Dr. K. A. Lord and Dr. C. Potter, of the Rothamsted Experimental Station, was read by the former, dealing with the insect aspect, and one by Dr. J. M. Barnes, of the Medical Research Council Toxicology Research Unit, Carshalton, dealing with the mammalian aspect. Prof. V. B. Wigglesworth (Cambridge) took the chair.

Prof. Wigglesworth spoke of the importance of biological interactions in the control of insect pests and the importance, therefore, of species-selective insecticides, as well as of the necessity for selectivity of a wider kind in the choice and development of insecticides less poisonous to man. He emphasized that a great deal is still to be learned about the biochemistry of selectivity. The systemic insecticide 'Schradan' is highly selective, but the mechanism is far from clear. Phytophagous caterpillars are notoriously immune, and, although they possess an unusually alkaline gut content, this can scarcely account for rendering innocuous a substance very resistant to alkaline hydrolysis. Something much more subtle is involved. Systemic insecticides also pose new problems in the matter of safety to man, since an insect poison incorporated into the structure of the plant is something new.

Dr. Lord said that, although the function of acetylcholine in myoneural transmission in mammals is well established and the toxic action of the organo-phosphorus compounds is undoubtedly mainly due to their inhibition of cholinesterase, even the existence of acetylcholine is not clearly established in insects, and it is far from certain that it has any important part to play. He felt, therefore, that the scope of investigation in insects should be widened to include other esterases which are also inhibited by the organo-phosphorus compounds. Crude extracts from insects have considerable activity in hydrolysing phenyl acetate, which has been used as a substrate in many experiments.

No general correlation has been established between insecticidal activity of various compounds and their ability to inhibit either cholinesterase or the general esterase *in vitro*. This is doubtless due to prior conversion of the compound *in vivo* as in the case of pure 'Parathion', which does not inhibit either esterase *in vitro* but is converted in *Tenebrio molitor* to a compound which does. In other cases lack of correlation may be due to physical factors, such as membrane permeability and partitioning between aqueous and lipoid phases, and it must be remembered that the enzymes are localized *in vivo* and that this localization is necessarily lost in making a crude extract.

Some organo-phosphorus compounds are toxic to insect eggs, although insufficiently in most cases to be of practical importance. Extracts of tomato moth eggs do not hydrolyse acetylcholine unless made from eggs in a late stage of development. Extracts from all stages hydrolyse phenyl acetate. Tetraethyl pyrophosphate (TEPP) at high concentration kills eggs at all stages, suggesting that the toxic action is exerted via the general—rather than the choline—esterase.

Dr. Barnes divided his description of the information on organo-phosphorus poisons on mammals into three parts: first, the acute effects and death; second, long-term and chronic effects; and third, the inhibition of cholinesterase. All cases of death are finally directly due to inhibition of respiration caused by the failure of neuro-muscular transmission, in most cases at both ends of the nervous system; but it is to be noted that some compounds, for example, 'Schradan', produce very little effect on the brain cholinesterase at the time of death, and in such cases failure of transmission may be confined to the muscle end of the nerve system. Fatal outcome can in many cases be avoided by application of artificial respiration until the internal mechanism of respiration has recovered, but the success of this depends on the reversibility of the cholinesterase inhibition. Different compounds differ in this respect; for example, among the phosphoric esters with an active group, those where the stable groups are methoxy are more easily reversed than where they are ethoxy, which in turn are very much more easily reversed than where the *iso*poproxy is concerned; and, in fact, artificial respiration fails to produce recovery after intoxication by di-*iso*propyl from the phosphonate.

In describing the long-term and chronic effects, Dr. Barnes again directed attention to the importance of reversibility, and mentioned also the prolonged paralytic effects resulting as a delayed action after severe intoxication with some compounds. This delayed action, which has operated in man, has not done so in the smaller mammals but can easily be experimentally demonstrated in birds. Unfortunately, the common factor among the compounds which produce this effect cannot be indicated, and so the probability of its occurrence must be determined entirely empirically.

In the case of mammals there is no doubt that the inhibition of cholinesterase is primarily responsible for the external symptoms; but as with insects, though in less degree, other esterases may be involved, and in fact it has been known for some time that the pseudo cholinesterase of serum is more effective in hydrolysing some other esters of choline than acetylcholine itself.

Dr. B. A. Kilby, of the School of Medicine, University of Leeds, opening the discussion, said that the mystery of 'Schradan'—a toxic substance not inhibiting *in vitro*—has been largely cleared up, oxidation to the amide oxide, an inhibiting and easily hydrolysed intermediate, being responsible. He felt that we should not be too afraid of compounds of high initial toxicity if they are quickly destroyed, and wondered whether the time has not come when we could contemplate the use of more toxic rather than less toxic insecticides.

During the discussion which followed, Dr. P. P. Hopf described some work in which the specific action of organo-phosphorus compounds against different enzymes appears very clearly. He has found, in working with diethyl phenyl phosphates, that the compound with chlorine substituted in the ortho position is very much more effective against the general esterase, while that with chlorine substituted in the para position is much more effective against cholinesterase. At a later stage of the discussion, Dr. W. N. Aldridge emphasized the extreme importance of chemical purity when examining the effect of organo-phosphorus compounds on enzymes *in vitro*, when there is a possibility of the compound under investigation being contaminated with a very much more active one. For example, esters of diethyl phosphoric acid are frequently contaminated with the extremely active inhibitor, tetraethyl pyrophosphate.

Dr. D. F. Heath pointed out that many of the reversible anti-cholinesterases depend for their absorption on the precise geometrical fit of two active centres in the molecule, and their specificity for different enzymes could doubtless be due to this stereochemical factor; whereas the majority of the organo-phosphorus inhibitors become covalently linked to one active centre in the enzyme, involving disruption of a link in the original compound. In this case, a lower degree of selectivity is to be expected, arising from modification of reaction-rates, influenced rather less drastically by stereochemical factors.

Taking up Dr. Kilby's query about the use of more highly toxic compounds, Dr. E. F. Edson discussed the human safety aspect. He emphasized that the relative toxicity to mammals and insects is important, and the new insecticide 'Malathon', having about a hundredth the toxicity of 'Parathion' to mammals and about a quarter of its toxicity to the majority of insects, can be regarded, therefore, as having a twenty-five-fold factor of safety in use. He was particularly concerned with the volatility of toxic compounds in regard to the risks of their use in the field, because the obvious protective measure, namely, the respirator, is an uncomfortable device under hot, sunny conditions, and workers are very inclined to evade its use. He mentioned that the safety aspects of 'Schradan' have been very fully investigated. His own information on rats and pigs indicates that a daily intake of about one two-hundredth of a lethal dose produces scarcely any detectable effect. Alone among the insecticides, this compound has been used to a considerable extent for therapeutical purposes (notably by Ryder and DuBois in the United States) in treatment of myasthenia gravis, and, although doses have been used requiring the additional use of atropine, many patients have been able to return to normal activities.

The afternoon session was concerned mainly with analytical aspects, under the chairmanship of Dr. J. R. Nicholls. Dr. G. S. Hartley, of Pest Control, Ltd., dealt with the behaviour of 'Schradan' in the living plant. Several lines of evidence lead clearly to the conclusion that the biochemical attack is in the first place an oxidation of a peripheral group in the molecule, and that it is probably basically similar to the oxidation occurring in the mammalian liver, but the conversion is very much slower. Oxidation of 'Schradan' in inanimate systems has also been examined, and recently Spencer and O'Brien in Canada have examined the effect of partial chlorination in anhydrous systems. Oxidation always produces an active inhibitor of cholinesterase, but one which is very unstable in water and leads to complete inactivation of the molecule by hydrolysis or partial conversion to a less active compound. Many steps in the oxidation are possible, as in the case of oxidation of simple tertiary amines, and the whole sequence of chemical processes is likely to be complex; but all the evidence points to each successive step of oxidation producing a compound yet more unstable than the last.

The amount of active inhibitor present during vegetable decomposition is always extremely small and follows closely the concentration of the reservoir of unchanged 'Schradan'. Were the observed inhibitions due to the much more toxic compound tetraethyl pyrophosphate, they are so small that they would be considered to be quite without toxic significance. The susceptible animal converts 'Schradan' to an inhibitor far more rapidly than the plant, and therefore the transient inhibitor attains much higher concentrations. It is therefore quite without importance whether a very small amount of conversion has previously occurred within the plant.

Dr. Hartley described some of the more recent work done by Dr. Heath and collaborators, which has unearthed a rather more stable vegetable derivative of 'Schradan' that is not itself an activator. The generally accepted view is that the active derivative has an amide oxide structure. The less active and more stable derivative has probably a hydroxymethyl group. He felt that the decomposition of 'Schradan' inside the plant has now been sufficiently explored to meet any reasonable doubts about the safety of this compound. Questions are still being asked as to whether the plant might not resynthesize some quite new toxic substance from the original insecticide, but he pointed out that there are many naturally toxic compounds in food crops, and an equal anxiety should really arise, therefore, with regard to the activities of the plant breeder and the applicant of fertilizers.

Dr. P. R. Carter, of Albright and Wilson, Ltd., gave a detailed account of the application of measurements of differential hydrolysis-rate to the analysis of mixtures of organo-phosphorus compounds.

Mr. J. F. Newman, of Imperial Chemical Industries, Ltd., then dealt with the technique of bioassay of the organo-phosphorus compounds. He said that chemical methods are always to be preferred for precise determination in cases where there is no doubt about the compound to be determined; but in many cases one does not know the full story about the chemical composition in relation to toxic effect, either because the original compounds are associated with active impurity, or because there may have been some conversion as a result of biochemical or weathering attack after application. Biological assay has therefore a necessary part to play, and it is also in the majority of cases capable of greater sensitivity, although of less accuracy than chemical methods. Mr. Newman described various devices for rendering biological assay methods more reproducible, and dealt with the importance of choosing the most suitable measure of intoxication, which is very rarely death itself. He said that he prefers, where possible, to use aquatic species, such as mosquito larvæ or daphnia, so that the toxic substance can be presented in a uniform environment.

There was general agreement with Mr. Newman's thesis that bioassay methods are absolutely necessary in many cases, although never so precise as chemical methods, and Mr. A. L. Bacharach pointed out that the development of pharmaceutical science owes a very great deal to the alternate use and comparison of biological and chemical methods of estimation.

Dr. Edson made a plea for a bolder approach on the part of the medical profession to the problem of permissible residues of toxic materials. The reluctance of medical workers to commit themselves as to what can be permitted as safe is doubtless due to the inherent difficulty of proving a negative. It is so much easier to prove that a large amount is dangerous than to prove that a small amount is safe; but he felt that the importance of the practical problem demands that people should be bold enough to make decisions, even at the risk of their being proved wrong by later generations. Dr. R. A. E. Galley supported this very realistic attitude, and quoted a remark of a distinguished contributor to this subject, that there is more danger of men's minds being poisoned against the use of insecticides than there is of their bodies being poisoned by the insecticides themselves.

G. S. HARTLEY

BRIGHTON AND HOVE NATURAL HISTORY SOCIETY

CENTENARY SESSION

THE Brighton and Hove Natural History Society will attain its centenary during the present session, which opened on October 10 with a review of the past hundred years by the general secretary, Mr. F. Edwards, followed by a conversazione.

The exact date of the founding of the Society is not known with certainty; but it was no doubt a natural development of some of the existing societies such as the Royal Literary Society. The proceedings at the early meetings, with the discussion thereon, were recorded in manuscript and consisted of papers by members; specimens of plants, fossils, etc., were often exhibited. An annual excursion to some place of interest was a regular feature which survived many years, and the earlier excursions were followed by a paper by the secretary, or other member, describing the features of interest observed, often including local legends and ancient history; sketches by a member have been preserved in a portfolio.

During the early period the papers read were all due to the members themselves, and, although later on non-members were invited to give addresses, it is only of recent years that the greater number of papers have been given by non-members. Summaries of the papers were given in the annual reports, and from about 1873 many of them were printed in full. In those days, also, the local newspapers often printed the transactions at the meetings in full, a contrast to the present day when a mention of the meetings is a rare occurrence.

The principal function of a society of this nature is the mutual exchange of scientific knowledge between the members themselves; but its activities should go beyond this, and it is expected that it should either make contributions to science by original investigations by members, or should increase the spread of knowledge by giving lectures to the general public. The Society's *Proceedings* include many papers in which details of local natural history, archæology, etc., are recorded, but there is little of investigations involving team-work. At various times the Society has sponsored public lectures, and at one time put up a guarantee for a series of lectures by well-known speakers; owing to want of support, the scheme was abandoned. From its inception the Society was active in forming a library of the standard scientific works of the time and also in collecting the *Proceedings* of learned societies and other natural history societies, and for a long while these books have been in the charge of the Brighton Corporation librarian.

For many years the Society has sent delegates to the meetings of the British Association for the Advancement of Science and of the South-Eastern Union of Scientific Societies, and when either of these bodies has met in Brighton the Society has undertaken the organizing of conversaziones, excursions, etc. Thus, at the British Association meeting at Brighton in 1872, no less than fifty microscopes were assembled at a conversazione, and a contribution was made to the Sub-Wealden boring at Netherfield, near Battle, which was undertaken in preparation for the meeting. More recently the Society has participated in the activities of the meeting of the British Association in 1948 and of the South-Eastern Union in 1947.

At various times sections were formed to cater for the special interests of members in various fields, and at one time up to seven were in being; but the only section which has had a more-or-less continuous existence is the Microscopical Section, which was first set up formally in 1870 and at the present time is one of the principal features of the Society.

The active life of a scientific society is principally due to a small number of members who keep things going, and the Brighton and Hove Natural History Society is no exception. The survival from the time a hundred years ago to the present day is largely due to two of the earliest secretaries, T. W. Wonfor, who held office during 1855–78, and E. A. Pankhurst, who reorganized the Society in 1886 and held office for sixteen years, before becoming president himself.

SOOTY BARK DISEASE OF THE SYCAMORE

A HITHERTO unreported fungus, *Cryptostroma corticale*, was noted on a dead sycamore in Wanstead Park, London, in 1945. Three years later, Mr. S. Walker had located about forty dead or dying sycamores in the Park, all of them infected with the same fungus, and it thus became obvious that a hitherto undescribed disease was active in the neighbourhood. The investigations carried out are detailed in Forestry Commission Leaflet No. 30 under the title "Sooty Bark Disease of Sycamore, *Cryptostroma corticale*"*.

It is now known that the fungus has a wider distribution. Up to July 1952 the fungus had been found south of London as far as Croydon and southwest as far as Guildford. To the west it has been recorded at Henley, while to the north-east it has been noted as far away as Mundford near Thetford in Norfolk. It has not been found outside the suburbs to the east and south-east of London. The information is based on partial survey only. In the London area the fungus is very generally distributed in parks and cemeteries but, so far, has only occurred on a large scale in Wanstead Park and a few neighbouring areas. One interesting point for further investigation is that whereas in Wanstead Park, and generally elsewhere in the London area, the fungus appears to be acting as a virulent parasite, in other areas, including all the occurrences outside London, the fungus is growing only on trees probably killed, or at any rate weakened, by other agencies. The effect of the fungus on the tree varies enormously. In some cases where it occurs it appears to behave as a severe parasite, killing trees of all sizes with considerable rapidity; but in other cases the effect may be relatively slight, attack being restricted to trees or branches of trees killed or damaged by other agencies. More requires to be known; but the disease constitutes a definite threat.

The organism believed to cause the disease forms hard black layers which separate, leaving shallow chambers in the tissue of the bark. The floor and roof of these cavities are kept apart by black columns up to 1 mm. long by 0·3 mm. in diameter, which usually persist after the shedding of the outer bark. The roof layer and the outer bark are eventually shed, exposing the spore mass, which forms a bluish-grey layer on top of the black floor layer. The tiny spores appear brownish-black in the mass and have a sooty appearance—hence the name of the disease. The first obvious sign of attack is often a blistering of the bark, which peels off, exposing the soot-like mass. Trees affected seriously should be felled, split up and burnt on the spot if possible; but control and prevention will require further research.

PRODUCTION OF OXYGEN FROM CHLOROPLAST PREPARATIONS

Photochemical Oxygen Production from Isolated Algal Chloroplast Fragments

SINCE the work of Hill[1] on the photochemical oxygen production by isolated chloroplasts, most of the experiments on this reaction have been done with chloroplasts from leaves. Chloroplast preparations from algæ have shown negligible activity[2].

We have made chloroplast preparations from unicellular algæ by mixing the cells with finely powdered alumina to make a thick paste, and forcing the paste through a fine crack in a steel cylinder under high pressure (details will be published later). The macerate is then taken up in 0·03 *M* phosphate buffer (pH 6·7) containing 0·3 *M* sucrose and briefly centrifuged twice at low speeds to remove the alumina and whole cells. The supernatant fluid contains finely divided chloroplast fragments ranging from diameters of about 2 μ down to below the limit of resolution of a light microscope. This fragmented chloroplast suspension, mixed with an oxidant (ferric oxalate–potassium ferricyanide[3] or quinone[4]), shows photochemical oxygen production with activities comparable to those reported for leaf chloroplast preparations[3]. The suspension of chloroplast fragments may be mixed with oxidant directly, or the fragments may be centrifuged down at high speed and taken up in fresh sucrose–phosphate buffer containing 0·01 *M* potassium chloride[4].

For comparison, we prepared suspensions of chloroplasts from *Phytolacca americana* either by macerating the leaves in a Waring blendor, or by forcing cut pieces of leaves through the pressure cylinder in the same manner as the chloroplast preparations were made from algal cells. The algal chloroplast material evolved oxygen at the same rate as *Phytolacca* plastids.

Oxygen production was measured manometrically with 7 ml. of washed chloroplast fragment suspensions containing a minimum of 0·51 mgm. chlorophyll/ml. in a box-shaped vessel of 13·6 ml. volume. The gas space was flushed with commercial nitrogen. The temperature of the experiment was 15°. The light source was a neon discharge tube with a red filter cutting out wave-lengths shorter than 580 mμ. Measurements with the Warburg–Schocken actinometer[6] indicated a radiation flux of $0 \cdot 14 \times 10^{-8}$ einsteins/min.-cm.^{2} at the position of the manometer vessel. It was necessary to reduce the light intensity with neutral filters to a level at which it can be measured accurately by this actinometer. The illuminated area of the vessel was 7·35 cm.^{2}. The rate of oxygen production, from either algal or *Phytolacca* chloroplast material, was 1·0 μl. oxygen/min., leading to a quantum requirement of 20–25 quanta absorbed per molecule oxygen produced. This yield is in reasonable agreement with corresponding measurements by French and Rabideau[5] and Ehrmantraut and Rabinowitch[7], and greatly exceeds that reported by Warburg[8]. Our results do not indicate that maximum efficiency has been attained, and further work on this aspect of the problem is in progress.

Active chloroplast fragments have been prepared from *Chlorella pyrenoidosa*, Chick (Emerson's strain), *Chlorella vulgaris*, Beyerinck (Pratt's strain), *Bracteococcus* sp. (this organism, also called *Dictyococcus*, was supplied by Dr. Richard Starr, Botany Department, Indiana University); *Scenedesmus obliquus* *D*-3 (Gaffron's strain) is the only organism we have been unable to break in the pressure cylinder. *Anabaena variabilis* (Hecker's strain) breaks very easily in the pressure cylinder, but its grana fragments do not show photochemical oxygen production, either in the whole macerate which contains phycocyanin in solution, or after the fragments have been centrifuged down and resuspended in fresh buffer.

Active Chloroplast Preparations from *Chlorella pyrenoidosa*

PUNNETT AND FABIYI point out in the preceding communication that our knowledge of the cell-free photochemical system from green plants has been mainly derived from leaves; recent knowledge of the physiological process of photosynthesis has been mainly derived from the study of unicellular organisms since Warburg[1] introduced the manometric method with cell suspensions. Warburg and Luttgens[2] established the first link between two fields of work by showing that both whole cells of *Chlorella* and the chloroplast preparations from leaves would reduce benzoquinone in light with the production of oxygen. However, quinone was the only known hydrogen acceptor giving a characteristic chloroplast reaction with *Chlorella*. While with the whole cells other hydrogen-accepting reagents gave results which have been interpreted with difficulty[3], quinone, by its lethal action and its apparently ready penetration of the cell wall, gave results equivalent to the cell-free preparations of chloroplasts from leaves. Thus, Punnett and Fabiyi have now provided the first direct method for comparing the activities *in vitro* and *in vivo* of the photochemical system from *Chlorella*—a 'classical' organism in the study of photosynthesis.

One of us (D. H. N.) has been using the Mickle cell disintegrator[4] for the preparation of cell walls from *Chlorella*. The cell walls may be spun off as a white layer; the cell-free supernatant green juice has been found to show reactions similar to the cell-free preparations from leaves of plants. We obtained results with hydrogen-accepting reagents essentially similar to those of Punnett and Fabiyi. The preparations also show the indirect photochemical reduction of methæmoglobin; this indicates the presence of a natural hydrogen-acceptor in *Chlorella* similar to the methæmoglobin-reducing factor found in leaves[5]. When the chlorophyll is removed from the cell-free *Chlorella* preparation with acetone, the cytochrome components are observed to resemble those characteristic of similarly treated chloroplasts from a leaf[6] and those directly observed in etiolated barley plastids[7].

The *Chlorella* cells were washed once with distilled water and transferred to the glass cups of the Mickle cell disintegrator. In each cup (2 cm. dia., 6 cm. long) were placed 5 ml. packed cells, 4 gm. glass beads (Ballotini No. 12, dia. 0·15 mm.) and, after cooling to 4°, cold distilled water to give a final volume of 11·0 ml. The disintegrator was run in a cold room at 4° for one hour and the suspension decanted from the glass beads. The suspension was spun for 5 min. at 1,500 *g* in an angle-head centrifuge. This gave a dark green supernatant and a deposit of three layers: at the bottom unbroken cells, then a mixture of the latter with cell walls and cell contents, and at the top a white layer of broken cell walls. The green supernatant was spun again at 1,500 *g* for a further 5 min. to remove any further solid material and kept at 0° for use in subsequent experiments. Chloroplasts from leaves of the garden pea and methæmoglobin factor from leaves of *Lamium album* were prepared, and activity measured by methods previously described[5]. The photochemical production of oxygen by the chloroplast preparations was measured in Warburg manometers with ferricyanide, using the procedure of Arnon and Whatley[8]. The chlorophyll concentrations in the stock suspensions were determined by the method of Mackinney[9].

When the dilute green juice of *Chlorella* was exposed to light in the presence of methæmoglobin, no appreciable reduction of the hæmoprotein occurred. The addition of methæmoglobin factor from *Lamium album* resulted in rapid and complete reduction. On centrifuging the green juice at 1,700 *g* for 40 min. the chlorophyll concentration was reduced to a twentieth. Thus twenty times the volume of the centrifuged juice could be added to give the same chlorophyll concentration in the reaction mixture. Under these conditions, methæmoglobin was slowly reduced in the light without the addition of the *Lamium* factor. The activity of these processes was measured in terms of $Q^{\text{chl.}}_{O_2}$ (µl. oxygen/hr./mgm. chlorophyll) and compared with the activity of pea chloroplasts (Table 1).

Table 1. REDUCTION OF METHÆMOGLOBIN

Total volume, 2·5 ml. 1·6 × 10^{-4} *M* methæmoglobin; 0·033 *M* phosphate buffer *p*H 7; reaction saturated with respect to light and to concentration of added factor. Factor prepared from *L. album*

	Half-time (sec.)	Chlorophyll (mgm.)	$Q^{\text{chl.}}_{O_2}$
Pea chloroplasts plus factor	55	0·24	2,100
Pea chloroplasts alone	1,500	0·24	77
Chlorella green juice alone	∞	0·30	zero
Chlorella green juice plus factor	112	0·20	1,170
Spun *Chlorella* juice alone	450	0·30	270

We may thus conclude that the chloroplast preparation from *Chlorella* is reactive with the methæmoglobin-reducing factor obtained from the higher plant. It may also be concluded that *Chlorella* contains a similar soluble methæmoglobin-reducing factor.

In Table 2 a comparison is given with pea chloroplasts in the production of oxygen from ferricyanide determined manometrically. In this case the light was below that required for saturation. The *Chlorella* preparation was found to lose one-half of the activity after 15 min. in the manometer at 15°. The pea chloroplasts preserved their activity and gave after 30 min. a stoichiometric production of oxygen. The production of oxygen was also confirmed by the hæmoglobin method[10] with ferri-oxalate as hydrogen acceptor.

Table 2. MANOMETRIC DETERMINATION OF OXYGEN PRODUCTION

	Initial rate (µl./hr.)	Chlorophyll per vessel (mgm.)	$Q^{\text{chl.}}_{O_2}$
Pea	270	0·294	920
Chlorella	140	0·238	590

The cytochrome components were examined with the Zeiss microspectroscope. Diluted green juice, equivalent to 0·4 ml. cells, was treated with 4 vol. acetone in the cold and the mixture filtered off in a Buchner funnel with a paper 4 cm. in diameter. After washing with cold acetone, the paper was allowed to dry, folded twice, moistened with phosphate buffer at *p*H 7 and immediately examined by transmitted light. A sharp absorption band was seen at 554–555 mµ (cytochrome *f* 555 mµ). Treatment with sodium hyposulphite resulted in a band at 563 mµ (cytochrome *b* in leaf chloroplasts 563 mµ), while the band corresponding to cytochrome *f* was unchanged. Carbon monoxide did not affect the bands. Treatment of the preparation with pyridine and sodium hyposulphite produced a strong band mainly of pyridine protohæmochromogen, and this seems principally to be derived from the cytochrome *b*. From the intensity of the spectrum observed, the ratio of cytochrome *f* to chlorophyll would be about 1 : 500, which is similar to that observed in leaves[11]. The band corresponding to cytochrome *f* from *Chlorella* appears to be slightly to the violet side of that from the leaf chloroplasts. This may be due either to the presence of a little cytochrome *c* or to an actual difference in the protein portions of the cytochromes.

It thus seems that certain systems connected with the process of photosynthesis have a wide distribution among types of green plants, as in the case of respiratory systems.

For his stimulating interest in connexion with this work we are grateful to Dr. Robert Emerson. The work is part of a programme supported by the Agricultural Research Council.

MECHANISM OF THE INCORPORATION OF ADENINE INTO ADENOSINE MONOPHOSPHATE

THAT purines might be incorporated directly into nucleotides, rather than first forming nucleosides that are then phosphorylated, was first suggested by Greenberg's[1] studies on the incorporation of formate into nucleotides. Williams and Buchanan[2] reported that the formation of inosinic acid (that is, hypoxanthine riboside-5-phosphate) by protein fractions from pigeon liver was greatly stimulated by addition of ribose-5-phosphate plus adenosine triphosphate. Goldwasser[3], working in this laboratory, has observed that adenine incubated in the presence of a particle-free pigeon liver extract was incorporated into adenine nucleotides.

In this communication we wish to summarize some new facts which may give the clue to the mechanism of one of the pathways of formation of adenosine monophosphate in animal tissues. Our experiments strongly suggest that adenosine monophosphate is the first nucleotide formed and that the overall reaction, starting from adenosine triphosphate, ribose-5-phosphate, and radioactive adenine, proceeds in two steps which we have been able to separate. The first step, catalysed by a heat-labile enzyme, is :

$$\text{Ribose-5-phosphate} + \text{ATP} \rightarrow \text{ribose-1,5-diphosphate} + \text{ADP}.$$

The second step, catalysed by a relatively heat-stable enzyme, is probably:

$$\text{Ribose-1,5-diphosphate} + \text{adenine} \rightarrow \text{AMP} + \text{phosphate}.$$

We propose that these enzymes be named respectively '5-phosphoribokinase' and 'nucleotide phosphorylase'.

The pigeon liver extract was prepared by homogenizing livers in 10 volumes of a medium consisting of 0·13 *M* potassium chloride; 0·015 *M* potassium dihydrogen phosphate; 0·01 *M* magnesium chloride, brought to *p*H 7·2 with potassium hydroxide. The homogenate was spun at 80,000 *g* and the particle-free supernatant was dialysed against the homogenizing medium. The dialysed extract was stored at − 20° and was stable for several weeks. The activity of the extracts was tested by incubating a small volume with 7 γ of 8-carbon-14-adenine (= 7,000 counts per minute). After 30–60 min. at 37° the carbon-14 content of the acid-soluble nucleotides was determined.

The dialysed pigeon liver extract did not incorporate appreciable amounts of carbon-14-adenine into the acid-soluble nucleotides, but the activity could be wholly restored by adding ribose-5-phosphate together with adenosine triphosphate. Either of these substances alone was relatively ineffective. Ribose-5-phosphate could be replaced by ribose-1-phosphate, but ribose-'3'-phosphate, deoxyribose-1-phosphate and ribose had only feeble effects when added with adenosine triphosphate. Adenosine monophosphate and inosinic acid were also ineffective as activators of the extract (Table 1). After separation by paper ionophoresis of the nucleotides formed from carbon-14-adenine, when ribose-5-phosphate and adenosine triphosphate were added, adenosine monophosphate had the highest specific radioactivity (Fig. 1).

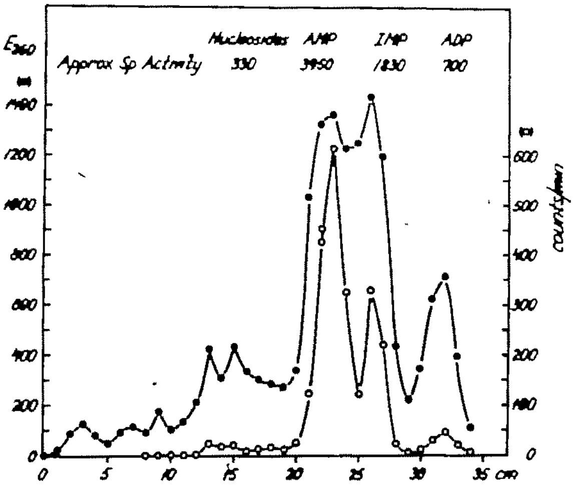

Fig. 1. Paper ionophoresis of substances formed after the incubation of a dialysed pigeon liver extract with 15 μ*M* ribose-5-phosphate, 6 μ*M* adenosine triphosphate and 140 γ carbon-14-adenine for 2 hr. at 37°

Abscissa: distance from starting line in cm.; ordinate: extinction × 10³ at 260 mμ.

The paper strip was scanned directly in the Beckman spectrophotometer at 260 mμ and was counted directly in a specially adapted Geiger counter

+ 1 μ*M* AMP	15
+ 1 μ*M* inosinic acid	15

7 γ = 7,000 counts/min. of 8-carbon-14-adenine added in every case

The undialysed particle-free pigeon liver extract was also stimulated by the addition of ribose-5-phosphate and adenosine triphosphate; but after heating such an extract at 65° for 5 min. the incorporation of adenine was decreased and could not now be stimulated by the addition of ribose-5-phosphate and adenosine triphosphate (Table 2). This observation suggested that the adenosine triphosphate-dependent enzyme is heat labile, but that the incorporation of adenine still occurs in a heated undialysed extract. That the incorporation of adenine takes place without the participation of adenosine triphosphate rules out the phosphorylation of adenosine[4] as a step in the formation of adenosine monophosphate under these conditions. The heat-lability of the adenosine triphosphate enzyme made it possible to demonstrate that adenosine triphosphate reacts with ribose monophosphate. The dialysed extract was incubated at 37° for 1 hr. with ribose-5-phosphate or ribose-1-phosphate and adenosine triphosphate. The incubation mixture was heated at 65° for 5 min. and the denatured proteins were spun off. Carbon-14-adenine was added to the supernatant. After a further incubation at 37° the nucleotides were analysed for carbon-14. The results (Table 3) clearly indicate that: (1) during the preincubation at 37° the ribose monophosphates reacted with adenosine triphosphate to form a substance from which the heated extract could form radioactive nucleotide with carbon-14-adenine; (2) the enzyme for the ribose-monophosphate reaction is heat labile; and (3) the adenine-incorporating enzyme is relatively heat-stable. The purification of the heat-labile enzyme is described in the following communication. After our work was completed, Korn and Buchanan[5] reported that one of the pigeon liver fractions needed for the synthesis of inosinic acid from hypoxanthine is also stable to heating. The heat-stable enzymes that form adenosine

monophosphate and inosinic acid may possibly be identical.

To support the supposition that ribose-1,5-diphosphate is an intermediate in the formation of adenosine monophosphate from adenine, ribose-1,5-diphosphate was prepared by the reaction of Klenow and Larsen[6]:

$$\text{Glucose-1,6-diphosphate} + \text{ribose-1-phosphate} \rightleftharpoons \text{ribose-1,5-diphosphate} + \text{glucose-6-phosphate}$$

and was used as an activator of the dialysed medium (Table 4).

A New Phosphokinase, 5-Phosphoribokinase

DURING an investigation of the enzymatic synthesis of adenosine monophosphate (see preceding communication) the existence of a phosphoribokinase was recognized. This communication outlines a partial purification of an enzyme from pigeon liver which catalyses the following reaction:

$$\text{Ribose-5-phosphate} + \text{ATP} \rightarrow \text{ribose-1,5-diphosphate} + \text{ADP}.$$

By analogy with the other phosphokinases we propose to call this enzyme '5-phosphoribokinase'.

The enzyme is assayed spectrophotometrically in the presence of an excess of 5-adenylate-kinase and 5-adenylate-deaminase, following the decrease in optical density at 265 mμ due to the deamination of adenosine monophosphate[1].

The reactions involved are:

$$\begin{aligned} 2\ \text{ribose-5-phosphate} + 2\ \text{ATP} &\rightarrow 2\ \text{ribose-1,5-diphosphate} + 2\ \text{ADP} \\ 2\ \text{ADP} &\rightarrow \text{ATP} + \text{AMP} \\ \text{AMP} &\rightarrow \text{IMP} + \text{NH}_3 \\ \hline 2\ \text{ribose-5-phosphate} + \text{ATP} &\rightarrow 2\ \text{ribose-1,5-diphosphate} + \text{IMP} + \text{NH}_3 \end{aligned}$$

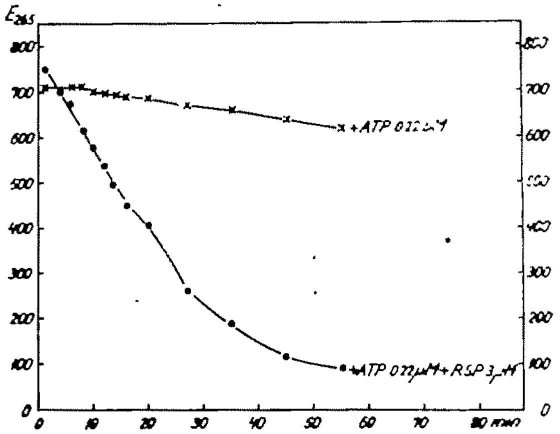

Fig. 1. The reference cuvette contained 0·22 μM adenosine triphosphate in 3 ml. and the spectrophotometer was brought to zero at an optical density of 0·5. The experimental cuvettes contained 0·39 mM potassium chloride, 0·03 mM magnesium chloride, 0·015 mM dipotassium hydrogen phosphate, 5-adenylate kinase 20 γ of protein per ml., 5-adenylate deaminase 25 γ of protein per ml., total volume 3·19 ml., pH 6·8. At time 0, 110 γ of protein per ml. of 5-phosphoribokinase was added to the experimental cuvettes

Abscissa: time in minutes; ordinate: extinction × 10^3 at 265 mμ

Fig. 1 gives the results of an experiment which shows that without the addition of ribose-5-phosphate there is practically no dephosphorylation of adenosine triphosphate. From the graph it is evident that the reaction stops when both energy-rich phosphate groups of adenosine triphosphate are used up.

The ribose-1,5-diphosphate formed can be isolated on a 'Dowex-1' formate column following the procedure of Klenow[2].

Preparation of the enzyme from pigeon liver involves the following steps: (1) homogenization of the tissue in 0·26 M potassium chloride, 0·02 M dipotassium hydrogen phosphate, 0·001 M magnesium chloride, pH 8. (2) Centrifugation at 30,000 g in the Spinco ultracentrifuge for half an hour. (3) Ammonium sulphate fractionation of the supernatant between 0·35 and 0·52 saturation in 0·01 M magnesium chloride at pH 8·5. (4) The precipitate is dissolved in 0·13 M potassium chloride, 0·01 M magnesium chloride, 0·0001 M glutathione, 0·015 M *tris*-hydroxymethyl aminomethane, pH 8, and frozen at − 20°. The next day the solution is thawed, and denatured protein is spun off. With this procedure a 12-fold purification is achieved.

The enzyme is inactivated by dialysis against the dissolving medium for 18 hr. at 4°.

This preparation of 5-phosphoribokinase has no action on D(−)ribose, ribose-1-phosphate, ribose-'3'-phosphate, D(+)glucose, glucose-1-phosphate, glucose-6-phosphate and D(+)galactose, but contains considerable 6-phosphofructokinase activity.

I am indebted to Dr. H. M. Kalckar for his encouragement and interest.

These studies were supported by grants from Carlsbergfondet, Rockefeller Foundation, Lederle Laboratories Division of the American Cyanamid Co., Istituto Sieroterapico Italiano and the Life Insurance Medical Research Foundation.

Determination of the Structure Factor of Thin Tin Films from Superconductivity Measurements

In a recent communication[1] on superconductivity of thin tin films, we mentioned the difference we found between the values for the magnetic threshold, the external field being parallel ($H^c_{\parallel}$) or perpendicular ($H^c_{\perp}$) to the support of the film (in both cases perpendicular to the direction of the current). We mostly use flattened strips of 'Pyrex' to support the films. Zavaritskii[2] has also found a difference between $H^c_{\parallel}$ and $H^c_{\perp}$.

Our films are prepared by condensation in vacuum or by sputtering in argon gas. As we remarked earlier[1], a very pronounced change is obtained for the form of the transition curve (R/R_0 as a function of an external field H) when the current increases. The transition curve becomes very sharp. We have now determined for different films, condensed or sputtered, the magnetic threshold values for $H_{\parallel}$ and $H_{\perp}$ for different values of the current and also as a function of temperature.

Table 1

				2 mA.	2,550	1,440	1·78
				5 mA	2,130	1,210	1·76
				10 mA.	1,395	850	1·64

In Table 1 are some results obtained with one of our condensed films in vacuum. This film has been measured three times on different dates, with the view of examining its behaviour; for certainly a change in the crystallization has occurred. After the second series of measurements the film was brought into contact with the air, so that an oxidation took place.

From the table we drew the following conclusions: (1) The ratio $H^c_{\parallel}/H^c_{\perp}$ is approximately constant as a function of current and temperature. Its value is between 1·5 and 1·8. Deviations occur near the transition temperature; but this seems to be due to errors in determining H^c. A small increase only is observed for the second series of measurements. (2) There is only a small variation of the ratio $H^c_{\parallel}/H^c_{\perp}$ in the different series of measurements in spite of the fact that the specimens have undergone several manipulations.

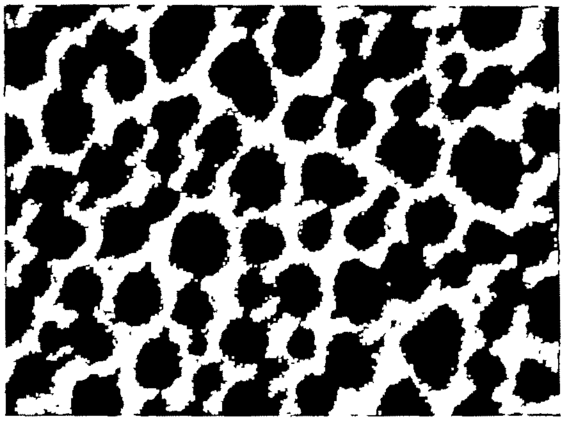

Fig. 1

For our sputtered films, we obtained for $H^c_{\parallel}/H^c_{\perp}$, as for our condensed films, constant values as a function of current, but which are larger. Thus we found $H^c_{\parallel}/H^c_{\perp} = 2$ in most cases, but in other cases a value of 5 was obtained.

The different results obtained can be explained by means of the demagnetizing factor. If we suppose that the layers are composed of flat ideal superconducting ellipsoids, we have $H^c_{\parallel}/H^c_{\perp} = 1/(1 - D)$ with $D = N/4\pi$. Thus we found for our condensed films $D = 0{\cdot}66$ and for our sputtered films $D = 0{\cdot}5$ and $D = 0{\cdot}8$ respectively, which correspond to a ratio m of the axes of 0·3, 0·5 and 0·15 (ref. 3).

On the other hand, pictures were taken of sputtered films (see Fig. 1) in our laboratory, for an earlier publication[4], by means of the electron microscope. From this picture the equatorial axes of the ellipsoidal grains can be determined; knowing, however, the ratio m from the magnetic measurements the thickness of the grains can be estimated. Thus we have been able to estimate the thickness of the grains shown in Fig. 1. For the largest grains (diameter 120 mμ), we obtained a thickness of 36 mμ, and for the thinnest one 7·5 mμ (diameter 25 mμ). This seems to be a reasonable thickness, taking into account the value of the resistance. But we may remark that the thickness seems to vary between wide limits.

We wish to thank the Department of Education, Brussels, for financial aid for this investigation.

Specific Ionization produced by Positrons and Electrons

ALTHOUGH ionization produced by an electron in its passage through various gases has been studied by previous workers[1], to our knowledge no experiment has been performed with the positron which will enable the specific ionization produced by a positron and an electron of the same energy to be compared. In the present experiment, this has been done by investigating the specific ionization by positrons and electrons in nitrogen and argon, using a fully automatic Wilson chamber. Rhodium-102 prepared by bombarding rhodium-103 by fast neutrons was used as the source.

The accompanying table gives the number and length of the tracks studied.

Element	No. of tracks Positron	 Electron	Length of tracks (cm.) Positron	 Electron
Nitrogen	174	263	1,662·9	3,183·2
Argon	187	282	2,169·2	3,257·6

Only those positrons and electrons the energy of which lies between 0·18 MeV. and 0·96 MeV. were taken into account.

Figs. 1 and 2 show the variation with $H\rho$ of specific ionization in nitrogen and argon, respectively, where H is the magnetic field and ρ is the radius of curvature of the track. In the case of nitrogen, the theoretical curve as calculated from the formula of Williams[2], having regard only to the $2p$-electrons, is also given. The ionization potential of the $2p$-electron for nitrogen in the molecular state is not known; consequently, we have taken the value for the atomic state, which is 15·5 eV. It can be seen from Fig. 1 that, within experimental error, there is no difference between the specific ionization produced by positrons and that by electrons, and also that the agreement between the theory and experimental results is satisfactory. According to Fig. 2, however, it appears that the specific ionization in argon by positrons is somewhat less than by electrons. It should be noted that at higher energies, where the accuracy of measurement is greater, the divergence between the two values nearly disappears. The difference is noticeable towards the lower energies where the higher concentration of ions along the tracks makes counting them an extremely tedious task, with the result that the subjective error is greater, as it is difficult to resolve two closely spaced ions. For this reason it is not possible to say with certainty whether the difference observed in argon between the positrons and electrons is real. The ideal conditions in which to study this effect would be by employing a low-pressure cloud chamber where greater accuracy in counting the number of ions could be achieved because of the smaller density of ions along the track.

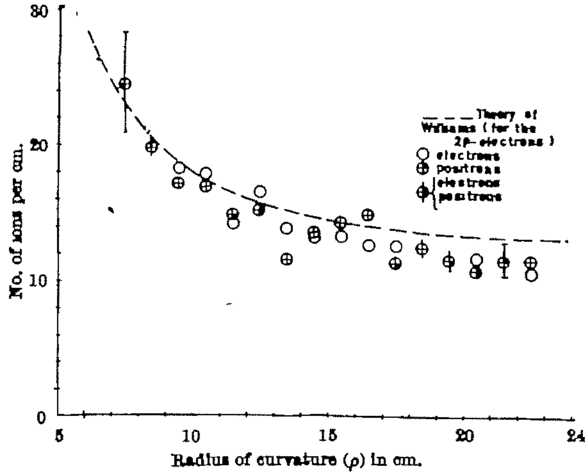

Fig. 1. Variation of primary specific ionization produced by positrons and electrons in nitrogen. $H\rho = 204 \times \rho$ gauss-cm.

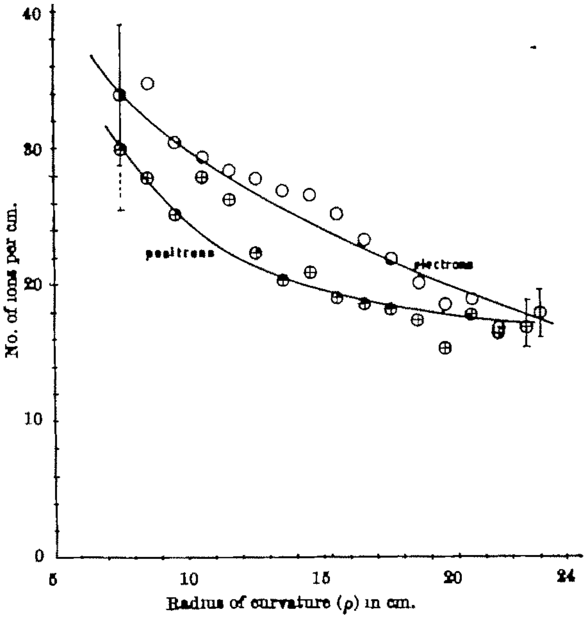

Fig. 2. Variation of primary specific ionization produced by positrons and electrons in argon. $H\rho = 204 \times \rho$ gauss-cm.

Recombination Coefficient in the F-Regions: a Possible New Process of Ionization of Nitrogen Molecules

IT is now generally recognized[1,2] that the high day-time rate of disappearance of electrons in the E- and F-regions of the ionosphere cannot be fully explained by the negative-ion formation theory of Bates and Massey[3], which takes account of the electron loss mainly due to attachment. The high value of the recombination coefficient in the E-region and in the upper parts of the D-region has recently been explained by A. P. Mitra and Jones[4] on the basis of dissociative recombination of electrons with O_2^+ and NO^+ ions, which are believed to be the principal ionized constituents at the heights of these regions. It may therefore be inquired if the process of dissociative recombination may not also be operative in the high F-regions (F_1 and F_2) and be the determining factor for the disappearance of electrons.

The ionized constituent in the F-regions is the O^+ ion. Hence, in order that dissociative recombination may be operative, the atomic ions must give rise to molecular ions. Now, the atmospheric constituents in the F-region are nitrogen molecules and oxygen atoms. Therefore, the formation of molecular ions is possible either by transfer of the charge of O^+ to the nitrogen molecule or by the O^+ ion associating itself radiatively with a neutral oxygen atom giving rise to an ionized O_2^+ molecule. The transference of charge from O^+ to the nitrogen molecule in the ground state is, however, forbidden, since the ionization potential of molecular nitrogen is greater than that of the oxygen atom. Also the process of radiative association is found to be too slow to explain the day-time recombination coefficient of the F-layers.

However, if one recalls that during daylight hours a considerable percentage of nitrogen molecules may be in the excited $A^3\Sigma_u$ state corresponding to the upper level of the Vegard–Kaplan bands, then a possibility of charge transfer suggests itself according to the reaction:

$$O^+ + N_2\,(A^3\Sigma_u) \rightarrow N_2^+ + O(^1S).$$

Here, the charge transfer is assumed to produce a N_2^+ ion in the ground-state, leaving the neutral oxygen atom in the metastable ^1S state.

Now, as the ionization potential of O is 13·55 eV. and the energy of the $O(^1S)$ state is 4·17 eV., an amount of energy 9·38 eV. is released. This energy is sufficient to ionize the nitrogen molecule in the $A^3\Sigma_u$ state (6·14 eV.), since the ionization potential of N_2 is 15·51 eV. Further, as there is almost exact energy balance, the reaction is highly probable. According to Bates and Massey[1], a resonance process of this nature may have a transfer coefficient of 10^{-11}. If we assume such a value of the coefficient, the concentration of excited nitrogen molecules required to explain the recombination coefficient in the F_2-layer (where the concentration of nitrogen molecules is 5×10^8) is 10^7. Thus, only 2 per cent of the molecules need be excited. Such a percentage is not improbable considering that the intensity of solar radiation in the band of wave-lengths (blue) causing excitation of the nitrogen molecules is very high.

It may be noted that the above process is operative only during the day-time, that is, as long as the concentration of excited nitrogen molecules is large. The contribution of dissociative recombination to the rate of disappearance of electrons falls to a low value in the hours of darkness. However, at night the absence of photodetachment increases the negative ion concentration, and this explains the night-time value of the recombination coefficient by the negative-ion theory alone.

The process discussed above shows how solar radiation in the visible range of wave-lengths may be instrumental in ionizing nitrogen molecules if positively charged particles are present. Incidentally, the process also explains the concentration of N_2^+ ions that is necessary to explain the twilight flash of the first negative bands of N_2^+, according to Wulf and Deming's hypothesis[5].

I am indebted to Prof. S. K. Mitra, under whose guidance the work reported above was carried out. I also wish to thank Mr. S. S. Baral for helpful discussions.

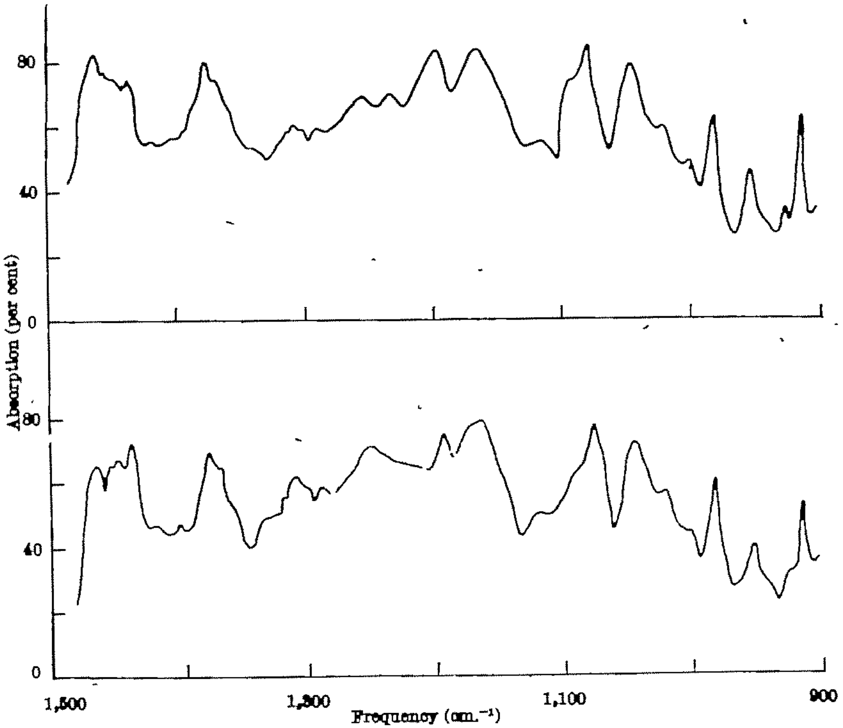
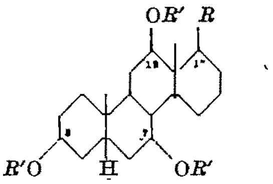
Specificity of Infra-Red Spectra

WE have recently examined the infra-red spectra (in carbon disulphide and carbon tetrachloride solutions) of a number of compounds of the general type (I), namely, 3α : 7α : 12α-trihydroxy steroids of the 5β (*A* : *B cis*) series with various groups *R* at C_{17}.



Upper graph: methyl 3α : 7α : 12α-trihydroxycoprostanate. Lower graph: methyl cholate

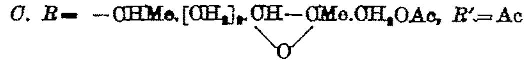
Fig. 1. Infra-red spectra of methyl 3α : 7α : 12α-trihydroxycoprostanate and methyl cholate from 1,500 to 900 cm.$^{-1}$. The compounds were dissolved in carbon tetrachloride for the region 1,500–1,300 cm.$^{-1}$ and in carbon disulphide for the remainder



(I)

A. $R = -\mathrm{CHMe.[CH_2]_2.CO_2Me}$, $R' = \mathrm{H}$

B. $R = -\mathrm{CHMe.[CH_2]_2.CHMe.CO_2Me}$, $R' = \mathrm{H}$



C. $R = -\mathrm{CHMe.[CH_2]_2.\underset{\diagdown O \diagup}{CH-CMe}.CH_2OAc}$, $R' = \mathrm{Ac}$

Most of the compounds were esters of bile acids; but some related carbinols have also been examined.

The important finding is that all the spectra so far examined are closely similar in the region 1,500–900 cm.$^{-1}$. Fig. 1 illustrates this, comparing the spectrum of methyl cholate (I*A*) with that of methyl 3α : 7α : 12α-trihydroxycoprostanate (I*B*) [1].

The same family likeness is observed in the spectra of the acetyl derivatives, including substances as different as scymnol tetraacetate (I*C*) and methyl triacetylcholate (I, *R* as in I*A*, *R*′ = Ac).

Although the infra-red spectrum of a compound in the region of the 'molecular fingerprint' (1,200–900 cm.$^{-1}$) has been accepted as providing an unequivocal identification[2], examples of two compounds with very similar spectra have been recorded among the sterols[3] and the triterpenoids[4]. The finding that a whole class of compounds possess virtually the same fingerprint spectrum must modify these views, since a confident identification is impossible when, for example, an isolated compound is not highly purified. The small differences which exist are mainly in the 1,500–1,350 cm.$^{-1}$ region; this region is characteristic of CH_2 and CH_3 bending vibrations to which the side-chain makes a large contribution. In favourable circumstances, it may prove possible to identify the side-chain from the spectrum.

It is expected that similar group resemblances will be shown by the spectra of compounds related to other bile acids, for example, by 3α : 7α-dihydroxy steroids related to chenodeoxycholic acid. If this is the case, it may help in establishing the constitution of new compounds which are related to known steroids.

My thanks are due to Prof. G. A. D. Haslewood and Dr. R. J. Bridgewater for kindly providing compounds.

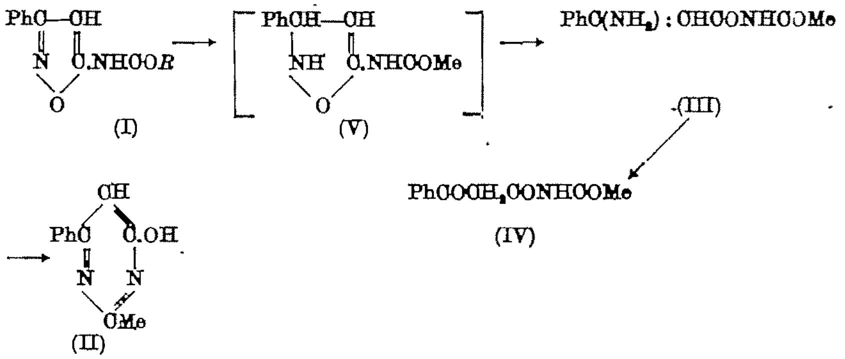
A New Synthesis of Pyrimidines

IT has been observed that the hydrogenation of 3-phenyl-5-acetamidoisooxazole (I; *R* = Me)[1] in ethanol using platinum or Raney nickel catalysts gives rise to a mixture of 2-methyl-4-phenyl-6-hydroxy pyrimidine (II) and *N*(β-aminocinnamoyl) acetamide (III), melting point 186°. When the latter compound (readily hydrolysed by cold dilute acid to (IV), melting point 105°) was melted, or when its aqueous solution was warmed, a facile cyclization to (II) occurred; taking this reaction into account, the final yield of the pyrimidine is almost quantitative. An intermediate in the hydrogenation may be the isooxazolin (V), by analogy with the products of hydrogenation of isooxazolones[2]. A similar series of compounds was obtained from (I; *R* = Ph).

The ready cyclization (III → II) provides an attractive basis for the biogenesis of the pyrimidine structure from the small metabolic units suggested from biochemical studies with isotopically labelled precursors[3], namely, a β-keto acid (or derivative), ammonia and a simple carboxylic acid.



A full account of this work and of similar reactions which are still being investigated will be reported elsewhere.

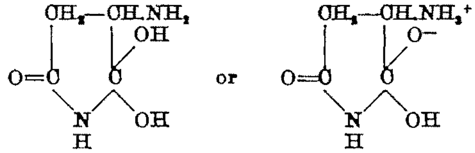
Contribution of the Ultra-Violet Absorption Spectrum of Asparagine to the Problem of its Structure

SINCE Steward and Thompson first proposed their new cyclic structure for asparagine indicated in the formulæ[1],



there have been a number of communications which have questioned this point of view[2]. In commenting on these communications, Steward and Thompson emphasized the importance of collecting evidence on

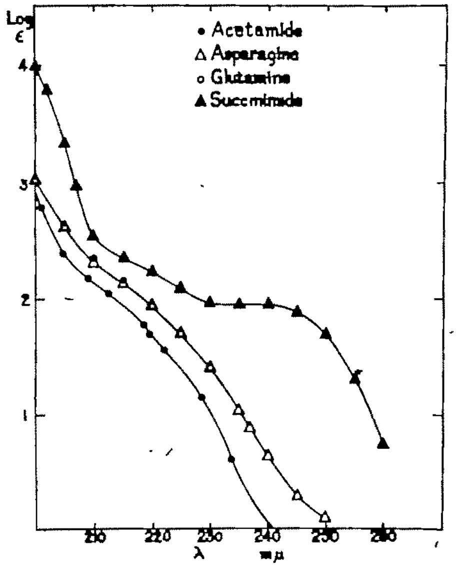


Fig. 1. Spectra of asparagine, glutamine and succinimide were obtained with a Beckman *DU* spectrophotometer using quartz vessels of 1 cm. depth and techniques discussed elsewhere (ref. 4) The acetamide spectrum was obtained by Ley and Arends (ref. 6)

solutions of free asparagine, since it is possible that crystalline asparagine and derivatives of asparagine may not conform to the cyclic structure[3].

No reference appears to have been made to the ultra-violet absorption spectra of water solutions of free asparagine and free glutamine[4]. In Fig. 1, the absorption curves are replotted as log ε versus wave-length (where ε is the molar absorptivity or molar extinction coefficient). The asparagine curve has been extended to longer wave-lengths, and absorption curves for water solutions of acetamide and succinimide have been included in the graph for comparison.

As part of a general study on peptide spectra, a number of unsubstituted and substituted amides have been examined. The detailed results will be presented elsewhere, but for the purposes of this communication it is sufficient to indicate that all the unsubstituted amides examined have the typical inflexion point at about 210 mμ exhibited by asparagine and glutamine. The long-wave-length band at about 240 mμ in the spectrum of succinimide is typical of diacylimides[5]. There is no indication of this band in the asparagine spectrum.

It might well be argued that hydration of one of the carbonyl groups of amino-succinimide would abolish the long-wave-length band to be expected of this compound; but it is difficult to understand how the proposed form of amide could fail to exhibit a spectrum quite different from the typical amide spectrum. One must conclude, therefore, that this evidence favours the straight-chain rather than the cyclic structure of asparagine.

New Specific Reagent for Keto-Sugars

During an investigation into factors which affect the reaction between sugars and anthrone[1], it was found that anthrone could, under certain conditions, be used as a specific reagent for keto-sugars and is suitable for identification of ketoses on paper chromatograms and in spot tests.

For hexose estimation the anthrone reagent is most effective in solution strongly acidified with sulphuric acid, when green-coloured sugar–anthrone complexes develop with both aldo- and keto-sugars. It was believed that if a condition could be attained in which keto-sugars would be affected preferentially to aldo-sugars, then only the former would afterwards react with anthrone. This condition is realized in a mildly acid medium, where a mixture of acetic acid and ethanol is used as a solvent for anthrone, and phosphoric acid is added to facilitate the required formation of ketose–anthrone complexes.

The reagent is prepared by dissolving 300 mgm. of anthrone (laboratory reagent, B.D.H.) in 10 ml. of glacial acetic acid, by warming, followed by the addition of 20 ml. of ethanol, 3 ml. of phosphoric acid (spec. grav. 1·60 at 20° C.) and 1 ml. of water. Freshly prepared reagent is to be preferred, although if it is kept in the refrigerator it can be used when several weeks old. On standing, crystals may separate out, but these are dissolved on warming the reagent.

For identification of sugars, the reagent is sprayed on a paper chromatogram or a paper treated with test solution. On heating at 108° C. for 5–6 min., mono-, di-, tri- and poly-saccharides containing keto-hexoses develop a bright yellow spot in white light. The keto-pentose (keto-xylose) available for testing gives a bright purple colour, whereas the two available keto-heptoses (D-glucoheptulose and D-mannoheptulose) give an orange-yellow. The developed colours do not fade easily and do not wash off with hot water; washed and dried chromatograms keep well. Under ultra-violet light, the keto-complexes appear brown, while the treated aldoses may show a light blue fluorescence.

The reagent appears to be specific for keto-sugars, and both furanose and pyranose structures in keto-hexoses give a positive test. Thus a strong reaction has been obtained with fructose, fructose-6-phosphate, sorbose, sucrose, turanose, melezitose, raffinose and inulin in addition to the keto-pentose and keto-heptoses mentioned above. No reaction was observed with the aldo-sugars, for example, arabinose, rhamnose, ribose, xylose, galactose, glucose, mannose, cellobiose, lactose, trehalose and dextrin. Sugar alcohols such as mannitol and sorbitol, and sugar acids, including galacturonic and glucuronic acids, do not give a colour reaction, nor do such compounds as inositol, ascorbic, α-ketoglutaric and uric acids; urea gives a grey-coloured spot, which is not likely to be confused with a sugar reaction colour.

For sugars consisting of hexose units, the colour intensity of the spots developed appears to be independent of the sugar itself, and depends only on the molecular concentration of keto-hexose units. Thus the depth of colour produced by 50 mgm. of sorbose, 50 mgm. fructose, 95 mgm. sucrose or 140 mgm. raffinose appears identical. This permits some quantitative estimation of the keto units present. The reaction is sensitive, 5 μgm. of mono-ketose being sufficient for identification.

Keto-xylose was prepared for this investigation from aldo-xylose by a method similar to that described by Hassid *et al.*[2].

I am indebted to Dr. Nelson K. Richtmyer, Laboratory of Chemistry, National Institutes of Health, Bethesda 14, Md., U.S.A., for kindly supplying D-glucoheptulose and D-mannoheptulose.

Plastic Sulphur

LIQUID sulphur is well known to become highly viscous when heated above 160° C.; this viscous sulphur (like selenium) is easily supercooled. At room temperature the product resembles unvulcanized rubber and is called 'plastic sulphur'. This hardens at liquid air temperature to a brittle glass, vitreous sulphur. At this temperature it remains amorphous for an indefinite time; at room temperature, however, the plastic sulphur crystallizes within a few hours, the crystallization proceeding (as with selenium) from the outside to the inside. We have found that impurities and other factors have some curious effects.

The property of supercooling is completely destroyed by heating the viscous sulphur in a vacuum. The freshly vacuum-baked or vacuum-distilled viscous sulphur crystallizes within a few minutes, when poured into water or liquid air. Older preparations preserved in a vacuum by sealing them off in glass bulbs do the same. The admission of air to the hot preparations spoils them in the long run, but not immediately.

A second fact is that, conversely, the addition of as little as 1 per cent of a trivalent element (phosphorus or arsenic) greatly facilitates the supercooling, the doped mass eventually staying amorphous for at least some months at room temperature. Daylight has no influence on this stability; the exclusion of air, though not necessary, is favourable.

This influence of trivalent elements suggests that the usual supercooling is connected with the presence of some nitrogen in the preparation. The elimination of this nitrogen by vacuum-heating would explain why vacuum-heating of viscous sulphur prevents supercooling.

All the facts known to us may be explained by assuming in viscous sulphur the presence of very long chains, S_∞, instead of the S_8-rings that are known to be stable at lower temperature, probably also in the liquid state below 160°. The long chains are presumably knitted together by the trivalent elements to form a network, more stable than the separate chains would be (compare the vulcanization of rubber).

The conception of long chains being built up above 160° also offers an explanation for the fact that traces of monovalent elements (1 per cent of bromine) greatly reduce the increase of viscosity at 160°, connected with their growth. We may suppose the halogen atoms to react with the terminal valencies of the chains at a rather early stage of their growth, thus stopping further growth until full length is attained. Such inhibition is well known in the production of linear polymers.

The assumption that polymerization occurs at 160°, and that this polymerization is linear, is difficult to prove by direct means. X-ray evidence is inconclusive, because of its insensitivity to minor changes in molecular arrangement in the liquid state. The indirect evidence offered above and by other authors, however, is strong. Moreover, the theoretically well-founded divalence of sulphur makes long chains (scarcely distinguishable from big rings) the most probable molecular shape for explaining the phenomena.

This investigation has been subsidized by the Dutch organization for fundamental research, F.O.M. It has, of course, many points in common with older or simultaneous investigations by others. References can be given only partially here[1].

Effects of Commercial and Radiation-produced Hydrogen Peroxide

RADIOBIOLOGISTS and radiation chemists have for many years been aware of the fact that hydrogen peroxide formed during irradiation may play a significant part as an agent of the changes brought about by ionizing radiations. The method of checking has often been to expose the test material to concentrations of hydrogen peroxide comparable with those produced by radiation, and hence to deduce what part of the radiation effects must be ascribed to other agents. However, such experiments may be misleading if commercial hydrogen peroxide is used, since the stabilizer which is usually present may inhibit the decomposition of hydrogen peroxide into the intermediates which take part in the particular reactions being studied. Information is not always made available by manufacturers about the nature of the stabilizers used; my experience has shown that they are sometimes sufficiently volatile to distil over with the hydrogen peroxide, if redistillation is employed as a precautionary measure.

Where stabilizer is present, it may very well happen that the hydrogen peroxide will be less effective by a considerable factor than the same concentration produced in clean water by ionizing radiation. In the course of studies on the effects of radiation on dilute aqueous suspensions of bacteriophage, I have made use of hydrogen peroxide from various sources, and only occasionally has the commercial product had as much effect as that formed by radiation. For example, in one series of experiments the survival curve for phage exposed to 50 γ/ml. of a redistilled commercial hydrogen peroxide was matched by that for phage exposed, in otherwise identical conditions, to about 1 γ/ml. of hydrogen peroxide, produced by 15,000 r. of X-rays.

It seems probable that, for the same reasons, the effects of metabolically produced hydrogen peroxide cannot safely be judged by experimenting with the commercial product. Experimenters in this field, too, may find it useful to work with hydrogen peroxide which is unequivocally free from stabilizer. Ionizing radiation offers a fairly quick and easy method of producing it, provided only low concentrations are required.

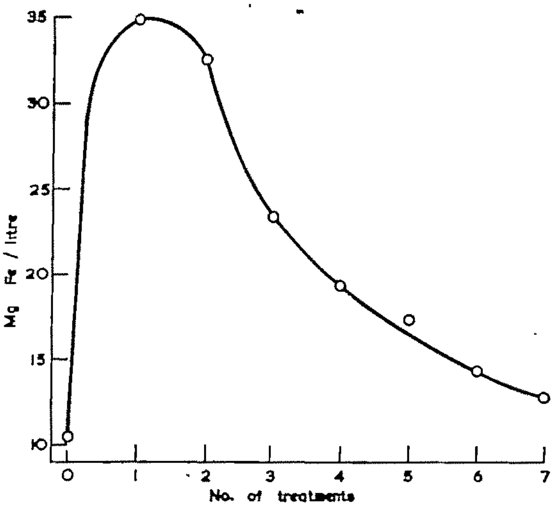
Sesquioxide Immobilization and Clay Movement in Podzolized Soils

AQUEOUS leachates of coniferous and broad-leaved forest litter readily dissolve hydrated ferric and aluminium oxides with the formation of soluble ferrous and aluminium complex compounds[1]. Further work on the properties of these complexes has shown that both the iron and aluminium compounds are strongly sorbed by soil sesquioxides and clay minerals.

It was previously suggested that the formation of the bleached A_2 horizon of a podzolized soil is caused by the solvent action of the leachates; it now seems that the subsequent immobilization of sesquioxides, which leads to the formation of the *B* horizon, is due to sorption of the iron and aluminium complexes on soil colloids, in particular the unattacked sesquioxides.

The sorption effect appears to be particularly marked in the case of the rimu (*Dacrydium cupressinum*) of New Zealand. If ferric oxide is treated with an aqueous rimu leaf extract, oxygen being excluded, the rate of solution of the oxide decreases until, after some three to four weeks, very little further increase in the concentration of dissolved iron takes place. At this stage the residual ferric oxide has acquired a very intense black colour. If the rimu–ferrous solution thus obtained is left in contact with fresh ferric oxide for a comparatively short period, it is found that extensive solution takes place —in a typical experiment, in 2 hr. the additional solution amounted to nearly 10 per cent of that obtained initially in 30 days. If the rimu solution is treated successively with fresh ferric oxide, the initial solution effect is quickly exhausted and gives place to an equally pronounced sorption of the dissolved iron. This sequence is illustrated by Fig. 1, which gives the results obtained by agitating a rimu–ferrous solution with ferric oxide for 15 min. and treating the centrifuged solution with fresh ferric oxide. The ratio of volume of solution/weight ferric oxide was the same in each treatment, so that this procedure reproduced the effect of percolating the original solution down a column of ferric oxide. It is significant, therefore, that the diagram corresponds to the distribution of iron down a podzolized profile; the solution stage represents the formation of the A_2 horizon, and the sorption stage that of the *B* horizon.

Percolation of a rimu–ferrous–aluminium solution down a column of ferruginous sand resulted in a net sorption of iron and aluminium, neither of which could be completely recovered by washing the column with water.



The experimental results thus indicate that sorption of the reaction products takes place concurrently with the solution process, and that the sorption has the effect of inhibiting further solution of the ferric oxide.

It has been found that the leachates can induce a marked deflocculation of both kaolinitic and montmorillonitic clay minerals. A calcium-flocculated suspension of montmorillonite which has been dispersed by addition of an aspen leaf extract may be reflocculated by addition of further calcium ion. Thus the concentrations of clay found in the *B* horizon of the Grey Wooded Soils of central North America, which are formed on calcareous materials under a predominantly aspen cover, may be produced by the leachates dispersing clay in the upper levels and transporting the dispersed material to lower horizons, in which the concentration of calcium remains sufficiently high to cause reflocculation and consequent immobilization.

Paper Electrophoresis of Streptomycins

MANNOSIDOSTREPTOMYCIN in some streptomycin preparations is conveniently detected by the paper chromatographic procedure of Winston and Eigen[1]. In the presence of high concentrations of salts such as in ion-exchange column eluates, or in fermentation broths, this procedure is not applicable: attempts to desalt such solutions, by mixed-bed ion-exchange, electrolytic de-ionization or solvent extraction, have proved unsuccessful. We have found it possible to separate streptomycin, mannosidostreptomycin and allied substances by paper electrophoresis, having developed (independently) a technique similar to that used for new antibiotic broths by Hosoya *et al.*[2], and King and Doery[3].

The apparatus is simple and consists of (*a*) a pair of electrode vessels ('Pyrex' dishes, 17 cm. × 27 cm. × 5·5 cm.), in each of which is situated a pure graphite electrode (20 cm. × 2·5 cm. × 0·5 cm.) with a platinum lead; (*b*) the support and cover for the filter paper (a pair of planar sheets of plate glass 28 cm. × 58·5 cm.), arranged horizontally on levelling screws between the electrode vessels. A cooling system was found to be unnecessary with a power pack providing 0–100 m.amp. at 300 volts.

Several grades of filter paper were examined; the most regular spots and highest loadings were obtained with Whatman No. 31 (thick). The paper is cut to size (24 cm. × 70 cm.), and the origin line is drawn 7·5 cm. from one end.

The solutions to be examined are applied to the origin line from a micrometer pipette, and the spots are allowed to dry. The paper is wetted evenly with *p*H 5·0 buffer (700 ml. 0·2 *M* sodium acetate plus 300 ml. of 0·2 *N* acetic acid) to within 0·5 cm. of each side of the origin line. The paper is blotted between blotting paper with a rubber roller and placed in position on the bottom sheet of levelled plate-glass, and the upper glass sheet is laid on top. About 300 ml. of buffer solution is added to each electrode vessel. The end of the paper farthest from the origin line is dipped into the cathode vessel, and the buffer is allowed to rise up the paper until the origin line is wetted and electrolyte continuity thus established. The end of the paper nearest the origin line is then dipped into the anode vessel, and the current is switched on. Sixteen hours later (overnight) the current is turned off and the paper is removed and dried, ready for spraying or laying on an agar plate seeded with a suitable organism[1].

We have examined a number of spray reagents; the following modified reagents are all suitable for detecting small quantities of streptomycin on paper.

(*a*) A diacetyl spray[4], which indicates streptomycin by means of its guanido groupings. The reagent (equal volumes of 0·1 per cent v/v aqueous diacetyl, 20 per cent w/v aqueous potassium hydroxide and 2·5 per cent w/v alcoholic α-naphthol mixed, in the order given, immediately before use) is sprayed on the air-dried paper. A magenta colour develops within a few minutes at room temperature if 5 μgm. or more of streptomycin equivalent is present.

(*b*) A naphthoresorcinol spray originally described[2] for the detection of carbohydrates, with a sensitivity for streptomycin similar to that of (*a*). The dry paper is sprayed evenly with the reagent (0·5 gm. of naphthoresorcinol dissolved in 225 ml. of ethanol and acidified with 25 ml. of concentrated orthophosphoric acid) and dried in an air oven at 100° C. for a minute or two until the background is faintly pink. The streptomycin spots are strongly fluorescent when viewed in ultra-violet light. In much higher concentrations the spots are visible in daylight, that from mannosidostreptomycin being pink and from streptomycin greyish.

(*c*) A spray reagent suggested by Partridge[5] for the detection of glucosamine, based on the Elson–Morgan reaction. The dry paper is sprayed with solution *A* (5 ml. of 50 per cent w/v alcoholic potassium hydroxide mixed, just before use, with 100 ml. of 1 per cent v/v acetyl acetone in redistilled *n*-butanol) and is heated in an oven at 100° C. for five minutes. After cooling, it is resprayed with solution *B* (0·5 gm. of *p*-dimethylaminobenzaldehyde dissolved in 15 ml. of ethanol, acidified with 7 ml. of concentrated hydrochloric acid and added to 90 ml. of redistilled *n*-butanol). Pink spots appear after reheating in the 100° oven for two or three minutes. This spray reacts with the N-methylglucosamine portion of the molecule. The reaction is somewhat less sensitive than that of (*a*) or (*b*).

Table 1

Substance	Mobility ($\mu \times 10^{-5}$)
Streptomycin	22 5
Mannosidostreptomycin	19·5
Streptothricin	24·0
Streptidine	24·9
Streptamine	6·3

A single paper may be used for sprays (*a*) and (*c*). The paper is first sprayed with the diacetyl reagent and the resultant spots are outlined before treatment with the Elson–Morgan sprays. It is necessary to use a separate paper for the naphthoresorcinol spray.

Table 1 shows average values for mobility, μ, calculated from the formula $\mu = dl/vt$, where d is the distance in cm. from the origin to the centre of the spot, v is the average of initial and final voltages applied and observed, l is the length of the paper in cm., and t is the time of migration in seconds. (These values are not corrected for electro-endosmosis; the effect of this was tested with glucose and found to be negligible with the buffer and paper recommended.)

The technical assistance of Miss I. Thompson is gratefully acknowledged.

Conjugated Phenols in the *Fusarium* Wilt Syndrome

VASCULAR discoloration is a prominent symptom of *Fusarium* wilt of tomato. Phenols are naturally occurring substances capable of discolouring plant tissues upon oxidation by phenoloxidases and polymerization to melanins. Phenoloxidases have been shown to occur in tomato stems[1]. Accordingly, the pathogen, *Fusarium oxysporum* f. *lycopersici*, could cause vascular discoloration by liberating phenols into the host's vascular system.

Initial experiments demonstrated that certain phenols are capable of discolouring the vascular bundles of tomato stems. Bonny Best tomato stems placed in solutions of phenols show vascular discoloration (but not wilting) within 3–24 hr., depending on the phenol, dosage and rate of transpiration. Orthopolyphenols are most active, certain metapolyphenols have slight activity, and one monophenol, carbolic acid, exhibits some activity (Table 1). Significantly, the vascular sap, exuded by root pressure from the stumps of diseased plants, contains more phenols than the sap of healthy plants. Mushroom phenoloxidase discolours the vascular sap of diseased

Carbolic acid	+	+++
Distilled water	−−−−	+

* (+) Discoloration relative to pyrogallol. Part, if not all, of the discoloration of the ambient solution is due to auto-oxidation of the phenol.

plants but is without effect on the sap of healthy plants. Thus, the evidence suggests that phenols are responsible for vascular discoloration in the diseased tomato stem. Accordingly, experiments were performed to determine the source of the phenols found in the sap of diseased plants.

The production of phenols by *F. oxysporum* f. *lycopersici* in artificial culture was examined. Neither phenols nor phenoloxidase was detected in the culture filtrate obtained from the growth of *F. oxysporum* f. *lycopersici* on an inorganic salt–glucose medium. This was demonstrated by the failure of two phenols, catechol and pyrogallol, or mushroom phenoloxidase to discolour the filtrate.

Although the pathogen may not be capable of synthesizing phenols, the phenols detected in the vascular sap of diseased plants could arise by the action of hydrolytic enzymes, produced by the pathogen, on the native conjugated phenols, such as glycosides, tannins or lignins, present in the host. The results in Table 2 demonstrate that *F. oxysporum* f. *lycopersici* can utilize salicin and tannic acid as the sole source of carbon for growth on Czapek's inorganic nutrient supplemented with micro-elements. The pathogen grew equally well on ¼ per cent sucrose (7·6 × 10^{-3} molar), ¼ per cent salicin (8·8 × 10^{-3} molar) and ¼ per cent tannic acid (15·5 × 10^{-3} molar). Growth was inhibited by higher concentrations of salicin and tannic acid. This experiment suggests that the pathogen produces hydrolytic enzymes which liberate phenols from β-glucosides and tannins.

A β-glucosidase capable of splitting salicin was detected in the sap of diseased plants, but not in that of healthy plants. 0·5 ml. of vascular sap was added to 10 ml. of 0·005 *M* salicin in 0·1 *M* acetate, *p*H 5; 1 ml. of toluene was added to each tube to preserve the reaction mixture. The tubes were incubated at room temperature (21 ± 1° C.). At fixed intervals 0·5 ml. of two-fold diluted Folin–Ciocalteu phenol reagent[1] was added to the reaction mixture, followed by 2 ml. of 20 per cent sodium carbonate. The tubes were shaken vigorously for 25 sec., placed in boiling water for 1 min., and immediately cooled with tap water. The intensity of the blue colour developed in the tubes by this treatment was measured with a Fisher electrophotometer using a 650-mμ filter. The coloured reaction product was diluted twofold prior to measurement. The results in Fig. 1 demonstrate the presence of an enzyme hydrolysing salicin in the vascular sap of diseased plants which was destroyed when placed in a boiling water-bath for 5 min. Enzyme activity was not detected in the vascular sap of healthy plants. Thus, the phenols found in the vascular sap of diseased plants could arise by hydrolyses of β-glucosides in the host. The carbohydrate fraction freed from the conjugated phenol might possibly function in the wilting mechanism characteristic of *Fusarium* wilt of tomato. Hodgson *et al.*[2] have shown that polysaccharides can cause plants to wilt.

Table 2. GROWTH OF *F. OXYSPORUM* F. *LYCOPERSICI* ON SALICIN, TANNIC ACID AND SUCROSE AS THE SOLE SOURCE OF CARBON

Carbon source	Concentration × 10^{-3} molar	Mycelium dry weight (mgm.)
Sucrose	7·6	12
Salicin	8·8	14
Salicin	17·6	17
Salicin	35·2	14·5
Tannic acid	15·5	12·5
Tannic acid	31·0	0·00

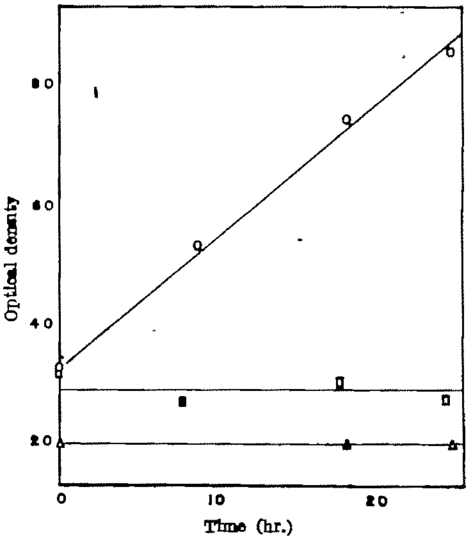

Fig. 1. β-Glucosidase activity of the vascular sap of diseased and healthy plants as measured by the hydrolysis of salicin. O, diseased; □, diseased boiled; △, healthy. Optical density signifies the colour intensity of the incubated enzyme-substrate reaction mixture after treatment with Folin–Ciocalteu phenol reagents. The difference in optical density of the vascular sap of diseased and healthy plants at the zero hour is due to the higher concentration of phenols in the vascular sap of diseased plants as identified with mushroom phenoloxidase

Significantly, if the base of a healthy tomato cutting is placed in a small volume of distilled water, the stem will develop vascular discoloration. Conceivably, all the components of the system responsible for vascular discoloration could arise from the host. Disruption of the host cells by the pathogen might liberate the factors responsible for the disease symptoms into the vascular system.

To summarize, phenols evidently are responsible for vascular discoloration in tomato plants infected with *F. oxysporum* f. *lycopersici*. The free phenols are probably derived from the host's conjugated phenols by the action of hydrolytic enzymes, produced by the pathogen. The host's phenoloxidase oxidizes the free phenols to coloured products. The same mechanisms could function in other plant diseases where vascular discoloration is a factor in the disease syndrome.

We wish to thank Miss Barbara Wooding for her technical assistance. The investigation reported here was done in co-operation with the Crop Protection Institute.

Utilization of Acetate in Experimental Diabetes

IT is well known that acetic acid occupies an important place in the intermediary metabolism, and that the participation of this substance in many reactions requires the activation of the acetate molecule. It is now generally considered that 'active acetate' corresponds to acetyl coenzyme *A*. Therefore, it appears reasonable to assume that a reduction of the acetylation of coenzyme *A*, that is, of the formation of 'active acetate', would lead to the accumulation of acetic acid.

It has been shown that acetic acid concentration in the urine of diabetics is higher than that of normal urine[1]. This may be attributed either to an increased acetate production or to a reduced acetylation of coenzyme *A* or both.

In order to test *in vivo* the extent of utilization of acetate in diabetes, normal and depancreatized dogs fasted 12 hr. were injected intracardially with different volumes of an acetic acid buffered solution. The doses employed were as follows: 100, 150 and 250 mgm./kgm. body-weight, expressed as acetic acid. Acetate solution of pH 7·4 was made by adding an appropriate amount of sodium acetate to acetic acid. The acetic acid concentration in the blood was estimated before the acetate inoculation and at various intervals after the inoculation (1, 5, 10, 15, 30 and 60 min.), according to a method previously described[2]. The acetic acid concentration in urine was also determined before and after acetate administration. It was found that, even before inoculation, the acetate-level in arterial blood was higher in the diabetic (average 11·2 mgm./100 ml.) than in the normal dogs (average 7·0 mgm./100 ml.). The injected acetate disappeared very rapidly from the blood of normal animals, whereas in diabetics it persisted for a longer period. In normal and depancreatized dogs, the rate of disappearance of acetate depends upon its initial concentration in the blood; hence the amount of acetate transformed in a given period is proportional to the amount injected. Taking as a representative index of the phenomenon the half-time for the recovery of equal quantities of acetic acid from the blood after the acetate injection, the values shown in Table 1 were obtained:

Table 1. HALF-TIMES FOR RECOVERY OF EQUAL QUANTITIES OF ACETIC ACID FROM BLOOD AFTER ACETATE INJECTION

Dose injected	Normal dog (min.)*	Diabetic dog (min.)*
100 mgm./kgm. body-weight	5	26
150 ,, ,, ,, ,,	4	15
250 ,, ,, ,, ,,	3	7

* Average of at least three experiments.

Acetate determinations in urine have shown that, under our experimental conditions, the amount of injected acetate eliminated by way of the kidneys may be neglected. Since 100 mgm./kgm. body-weight appeared to be the smallest dose necessary to make the phenomenon appreciable, such a dose has been chosen as standard for the study of the behaviour of ketone bodies after acetate administration. We found that in the normal dog the increase of the blood-ketone level was very small and fleeting after acetate injection, whereas in the depancreatized dog such an increase was much greater and lasting. The average values obtained are summarized in Table 2.

Table 2. THE BEHAVIOUR OF BLOOD KETONE BODIES AFTER INJECTION OF 100 MGM. OF ACETIC ACID/KGM. BODY-WEIGHT

	Total ketones in blood expressed in terms of β-hydroxybutyric acid (mgm./100 ml.)	
	Normal dog*	Diabetic dog*
Before inoculation	0·85	10·5
1 min. after inoculation	1·10	11·0
5 ,, ,, ,,	1·40	12·5
10 ,, ,, ,,	0·85	13·1
15 ,, ,, ,,	0·90	13·0
30 ,, ,, ,,	0·92	11·5
60 ,, ,, ,,	0·92	11·3

* Average of at least three experiments.

It is to be noted that the labelled acetate, injected either into an intact or an eviscerated animal, is oxidized to carbon-14 dioxide[3,4], and that in our experiments acetate administration leads to the production of ketone bodies. These facts indicate that the injected acetate has been rapidly activated. The marked difference in speed of disappearance of injected acetate observed between normal and depancreatized dogs shows that the utilization of acetate in diabetes is reduced compared with the normal. Since without activation acetate is a metabolically inert form, it tends to accumulate and to be eliminated with urine in greater amount than normal.

These observations suggest that in diabetes, in addition to other known enzymatic changes, the acetylation of coenzyme *A* is reduced.

Effect of Five Strains of Fowl-Plague Virus on a Sulphonphthalein Dye

KUNST[1] examined the effect of different strains of influenza virus on sulphonphthalein dyes and found that when various dyes of this group were inoculated into the allantoic fluid of eleven-day old chick embryos in the presence of swine influenza virus they faded after 48 hr., whereas the human strain of influenza virus *A* induced much less change though the hæmagglutination titres of the two strains were more or less similar.

The following experiment was carried out in an attempt to differentiate between five different strains of fowl-plague virus using one of the sulphonphthalein dyes, namely, phenol red. The virus strains used were :

Fowl-plague, original strain	$PFO_3P_{11}O_{38}$
Fowl-plague, attenuated strain,	$PFO_3P_{11}O_{38}P_{38}O_1$
Fowl-plague, reactivated strain,	$PFO_3P_{11}O_{38}P_{18}O_{18}$
Fowl-plague, mice strain,	$PFO_3P_{11}O_{38}M_{38}O_1$
Fowl-plague, tyroid strain,	T_{111}

The experiment was carried out in the following steps : (1) A 1 : 1,000 solution of the dye in 0·01 *N* sodium hydroxide was prepared. (2) 3 ml. of 10^{-3} solution of the virus in phenol red was inoculated into the allantoic cavity of three eleven-day old eggs ; three chick embryos inoculated with phenol red alone served as controls. (3) The inoculated embryos were incubated at 37° C. for 48 hr. and the allantoic fluid of each egg was aspirated separately and tested for freedom from bacterial contamination. (4) The colour intensity of the sterile chorio-allantoic fluid was determined, arbitrary units being given to designate this intensity ; + + + + indicated the original deep red colour of phenol red, while 0 represented complete discharge of the red colour. All degrees of intergradation which existed between these two extremes were given respective arbitrary units between these two.

The results obtained from the above experiment are presented in Table 1.

Table 1. EFFECT OF FIVE DIFFERENT STRAINS OF FOWL-PLAGUE VIRUS ON PHENOL RED IN CHICK EMBRYOS

Virus strain	Colour intensity of chorio-allantoic fluid (arbitrary units)
Phenol red (control)	+ + + +
Fowl-plague, original, $PFO_3P_{11}O_{38}$	+ + + +
Fowl-plague, attenuated, $PFO_3P_{11}O_{38}P_{38}O_1$	+ + +
Fowl-plague, reactivated, $PFO_3P_{11}O_{38}P_{18}O_{18}$	+ +
Fowl-plague, mice, $PFO_3P_{11}O_{38}M_{38}O_1$	+ + ±
Fowl-plague, tyroid, T_{111}	±

The results in Table 1 show that the five strains of fowl-plague virus used in this experiment possess varied powers of discharging the colour of phenol red in allantoic fluids inoculated with each of them separately. Thus the reactivated strain induced a notable decrease in the colour intensity of the allantoic fluid as compared to the controls. The change in intensity was much less when the dye was inoculated together with the attenuated strain, whereas the original strain of fowl-plague virus failed to induce any change in the colour intensity. The change in colour by the mice strain was of intermediate nature between that induced by the attenuated and reactivated strains, while the tyroid strain induced almost complete discharge of the colour of the infected allantoic fluid.

Determination of the *p*H-value of the infected chorio-allantoic fluids showed that the decrease in the colour intensity was accompanied by a similar decrease in the *p*H value. Thus, the chorio-allantoic fluid inoculated with the original strain which showed a deep red coloration very similar to that of the control gave a *p*H-value of 8·0, while that infected with the tyroid strain had a *p*H value of 6·3, which would explain the complete discharge of colour of phenol red by this virus. This result is, however, contrary to the findings of Kunst (*loc. cit.*), who claimed that there was no change in the *p*H of the allantoic fluid during the development of swine influenza and human influenza *A* viruses, though they induced different changes in the colour intensities of the allantoic fluid inoculated with a mixture of each of them and a series of sulphonphthalein dyes.

It is suggested that this method, if worked out thoroughly, might serve as an easy means of separating closely related virus strains.

A Selective Method for the Staining of Negri Bodies in Histological Brain Sections

SEVERAL techniques have been devised for the demonstration of Negri bodies in histological preparations ; but many of them, in my experience, proved to be sometimes capricious and not always reliable. Hitherto, in this laboratory routine examinations for rabies are carried out by staining sections of the hippocampus with a slightly modified Heidenhain's iron hæmatoxylin. This technique was found to be extremely reliable, and Negri bodies appear as blue-black well-defined structures, often containing black granules and vacuoles. However, as the whole background is greyish-black and red blood corpuscles, glial cells and leucocytes stain black also, some confusion may occasionally be encountered while differentiating Negri bodies. In view of this drawback, another method has been evolved, which gives very selective, durable and constant staining of Negri bodies.

The method described below is based upon picro-Mallory modifications of Lendrum and McFarlane[1] and McFarlane[2]. The picro-Mallory techniques were originally devised for the staining of connective tissue ; however, advantage has been taken of the principles of the method in order to demonstrate Negri bodies.

The method is as follows. Stain paraffin sections in Ehrlich's hæmatoxylin (5 min.). Blue in tap water for 2 min. Orange *G* ½ per cent in saturated aqueous solution of picric acid (1 min.). Wash in tap water until only erythrocytes remain stained yellow. Rinse in distilled water and stain for 10 min. in the following solution : acid fuchsin (0·5 gm.), phosphotungstic acid (0·5 gm.), 1 per cent acetic acid (100 ml.). Rinse in distilled water and differentiate for 5 min. in the following solution : phosphotungstic acid (2 gm.), phosphomolybdic acid (2 gm.), saturated aqueous picric acid (70 ml.), absolute alcohol (30 ml.). Rinse in distilled water and then in 1 per cent acetic acid. Stain for 15 min. in 1 per cent anilin blue in 2 per cent aqueous acetic acid. Rinse in 1 per cent acetic acid, dehydrate, clear and mount.

Negri bodies are stained purplish-red with blue granulations, cytoplasm of neurones bluish, nucleoli dark purple and erythrocytes yellow.

Stimulation of the Growth of the Radicle after Treatment of Tomato Seed with Bromine Water

DURING investigations into the minimum time necessary for surface-sterilization of tomato seed with bromine solution, it was noted that certain treatments stimulated growth of the radicle.

Hybrid seeds obtained from the crossing of two inbred lines of tomato (*Lycopersicum esculentum*, Mill.) were used in all experiments. The inbred lines were derived from the varieties Pritchard and Red River. Pritchard was used as the maternal parent. Samples of seed were immersed in a 0·5 per cent solution of bromine (vol./vol.) for varying lengths of time and then washed quickly with sterile distilled water until all coloration disappeared.

The effect of time of immersion in bromine solution on growth of the radicle, with seed germinated in the sterile standard medium[1] used for culture of excised tomato roots, is shown in Table 1.

Table 1. EFFECT OF INCREASING TIME OF IMMERSION OF SEEDS IN BROMINE SOLUTION ON LENGTH OF RADICLE, NUMBER OF LATERAL ROOTS PER RADICLE AND LENGTH OF FIRST LATERAL AT SEVEN DAYS AFTER 'SOWING' (SEEDS GERMINATED IN WHITE'S MEDIUM)

Length of bromine treatment (min.)	Mean length of radicle (mm.)	Number of laterals per radicle	Mean length of first lateral (mm.)
½	67·0 ± 4·06 (11)	12·5 ± 1·50	15·8 ± 2·80
1	75·6 ± 3·52 (13)	13·6 ± 1·72	17·1 ± 1·45
2	79·1 ± 3·40 (11)	14·5 ± 1·53	23·5 ± 1·91
4	73·7 ± 4·06 (12)	10·9 ± 0·81	19·8 ± 2·19

The results show that growth in length of either the radicle or the first lateral, and number of laterals, were greater with an immersion time of 2 min. compared with an immersion time of 0·5 min. The experiment was repeated with seed germinated on moist filter paper in sterile Petri dishes. Observations of the number of seeds germinated were made at 30, 42, 48 and 102 hr. after sowing, at which time the radicles were measured. Results are shown in Table 2.

Table 2. LENGTH OF RADICLE AT 102 HR. AFTER SOWING WITH SEEDS SUBJECTED TO DIFFERENT PERIODS OF TREATMENT WITH BROMINE SOLUTION

Length of bromine treatment (min.)	All seeds germinated by 42 hr. after sowing		All seeds germinated by 42 hr. after sowing, but with radicles less than 2 mm. long	
	No. of seeds	Mean length of radicle (mm.)	No. of seeds	Mean length of radicle (mm.)
0	36	34·8 ± 0·935	31	33·7 ± 0·950
½	30	51·2 ± 1·738	19	48·1 ± 1·37
1	33	50·3 ± 1·650	22	46·1 ± 1·79
2	25	45·7 ± 1·192	15	43·9 ± 1·56
6	27	33·0 ± 1·289	18	32·1 ± 1·26

A second run with seed germinated on moist filter paper was made using a greater number of replicates and germination observed at 24, 30, 33, 36, 42, 48, 54, 66 and 102 hr. after sowing. The lengths of radicles at 102 hr. after sowing were 40·5 ± 1·32 (103) for untreated seed and 60·5 ± 1·32 (104) for treated seed.

There was no detectable effect of bromine treatment on either viability or 'germination-rate' in either run. Bromine treatments of ½, 1 and 2 min. produced an increase in growth of the radicle compared with untreated seed. Growth of radicles with seed treated for 6 min. was less than that in the other bromine treatments.

The evidence is insufficient to justify any conclusions as to the mode of action of bromine on growth of the radicle. The fact that bromine treatment gave stimulation with seeds germinated either when immersed in culture solution or on moist filter paper indicates that there is a direct effect on the seed or radicle, and not an indirect effect due to reaction of bromine with some unfavourable environmental factor. Taylor[2], using celery seed, showed that either time of emergence of the radicle with seed sown in Petri dishes, or time of emergence of the seedling with seed sown in soil, was decreased when the seed was treated with calcium hypochlorite. Similar treatment also decreased time of emergence of pre-sprouted seed sown in soil. Similar experiments using seed of tomato (hybrid Pritchard × Red River) sown in soil have been carried out at my present address. No decrease in time of emergence and no increase in height or dry-weight of the seedlings was detected at two weeks after sowing.

Burkholder and McVeigh[3] found that treatment of seeds with calcium hypochlorite may affect the formation of niacin, pantothenic acid and riboflavin during germination. Consideration of these points suggests that synthesis of the vitamins may be related to a process which is affected by halogen oxidizing agents, and that radicle growth in the tomato hybrid used here may be limited by the balance of vitamins synthesized during germination and early growth.

A *Chalaropsis* on Beech

DURING an investigation of fungi on recently felled beech, attention has been directed since April 1952 to an abundant fungus in Knole Park, Sevenoaks, which sporulates at the interface between wood and bark. It is also abundant, but in small patches only, on the sap-wood of stumps.

Externally normal bark can be removed a month after felling to expose a black sludge, sometimes 3 ft. in length, of thallospores of an apparently undescribed species of *Chalaropsis*. Intermixed with this are infrequent perithecia of a species of *Ceratocystis* (*Ophiostoma*), with a brimmed ascospore, which culture has shown to be the perfect stage of the *Chalaropsis*. As well as the blackish thallospores, hyaline endospores are formed both on the wood and in culture. Further, intermixed with the sludge are other species of *Ceratocystis* but in small amount. Woodlice, commonly seen below the bark of affected felled trees, leave a frass consisting largely of viable thallospores of *Chalaropsis*.

Chalaropsis thielavioides Peyronel, causing walnut graft disease in Great Britain[1], is the only previous record of a species of the genus in Britain; but the perfect stage is unknown and the thallospore measurements are significantly different from those of the *Chalaropsis* on beech. The only other *Ceratocystis* with a brimmed ascospore and a *Chalaropsis* stage is *Endoconidiophora variospora* Davidson, reported from oak tan bark in the United States[2]; but this also seems to differ from the beech species.

There is no definite evidence that the fungus attacks living trees; but field observations have shown an initial infection of wounds in standing trees.

Sometimes the *Chalaropsis* and more frequently the accompanying *Ceratocystis* spp. are parasitized by *Gonatobotryum fuscum* Sacc., its parasitism showing some similarity to that of *Gonatorrhodiella highlei* A. L. Sm. on *Nectria*[3].

Chemical Mutagenesis in Bacteriophage *T2*

PROFLAVINE (2-8 diamino acridinium sulphate, Abbott) in concentrations of 3–4 γ/ml. prevents liberation of infectious bacteriophage *T2* from *Escherichia coli*, strain *B*, without preventing lysis[1]. The bacteria liberate incomplete non-infectious phage particles[2]. If proflavine is removed before lysis, the yield of complete phage is normal or subnormal. We have detected a mutagenic effect on phage produced in proflavine-treated bacteria.

E. coli B was infected with phage *T2* in a synthetic medium (glucose, 4 gm.; ammonium chloride, 1 gm.; magnesium sulphate, 0·12 gm.; disodium hydrogen phosphate, 6 gm.; potassium dihydrogen phosphate, 3 gm.; water, 1,000 ml.; *p*H 7·0), with or without 4·0 γ/ml. proflavine added at the time of infection. Proflavine was removed 17 min. after infection by a 1 : 100 dilution. The phage yield from proflavine-treated cultures contained many more plaque-type mutants *r* and *w* (see ref. 3) than the control phage yield (see table).

	Mutants *r* and *w* in bursts of phage *T2*					
	No. of plates	Average No. of bursts per plate	No. of bursts examined	Plates with mutants	Total yield	Total mutants
Exp. 1						
Control	100	2·7	270	1	25,000	15
Proflavine 4·0 γ/ml.	100	2·65	265	43	26,000	201
Exp. 2						
Control	40	4·1	165	2	—	9
Proflavine 4·0 γ/ml.	42	4·3	180	28*	—	123

* Four plates had mutants of two distinct plaque types.

The mutants include the same variety of plaque types as the spontaneous mutants. In the yields from individual bacteria the mutants are distributed in clones, with distribution of clone size roughly similar to that observed with spontaneous mutants[4]. The effect of proflavine appears, therefore, to be an increase in mutation-rate over the rate of spontaneous mutations. Experiments directed towards detecting any selection by proflavine in favour of plaque-type mutants were negative. There was no preferential loss of clones containing r^+ phage only, nor any increase in the proportion of *r* particles in the yield of bacteria infected mixedly with $T2r^+$ and *T2r*.

Proflavine increased the frequency of *r* mutant in a *T2w* stock. In presence of proflavine, the rate of the mutation $T2r \rightarrow T2r^+$ was not increased enough over the spontaneous rate (about 10^{-7}) to allow detection of any r^+ mutants among 3×10^4 particles from proflavine-treated bacteria. Preliminary experiments indicate a slight effect of proflavine on the mutation $T2 \rightarrow T2h$.

Proflavine is an effective mutagen for bacteria. Treatment of washed cells of a streptomycin-dependent strain of *E. coli*[5] with 4·0–20·0 γ/ml. proflavine (1 hr. at 37° C. in distilled water) produces no sterilization of bacteria but increases 6–10 times the number of colonies they produce on nutrient agar without streptomycin.

This work was done under a predoctoral fellowship from the National Foundation for Infantile Paralysis and under the direction of Prof. S. E. Luria; it was supported in part by a grant from the American Cancer Society (upon recommendation of the Committee on Growth).

Eye Movements in Connexion with Television Viewing

THE present-day British system of television makes use of the line interlace system whereby frames each containing only half the total picture information, are presented at the rate of 50 per sec. The advantage of this system compared with the sequential system, in which each frame contains the total picture information, is that it gives a subjective increase in the maximum amount of information that can be transmitted in a given band-width. A disadvantage of the interlace system is that pictures of still objects may show instability associated with the interlace and those of vertically moving objects may appear non-interlaced with the raster drifting slowly in the direction of movement (that is, 'crawling'). Gouriet[1] has suggested that differences in the pattern of eye movement when viewing sequential and interlaced pictures could account for these phenomena.

Using the photoelectric corneal reflex apparatus[2], an investigation of the problem has therefore been made. Records have been obtained of the movements of one eye for binocular viewing of a 9-in. television screen for both sequential and interlaced scan with the picture present and with the picture suppressed. Viewing distances of 34 cm. and 120 cm. were used. The latter distance was the minimum for direct viewing that the configuration of the apparatus would allow; for the shorter distance, the subject viewed an image of the screen formed by reflexion in a plane mirror. Records for fixation of a pointer moving vertically across the screen for both sequential and interlaced scan with picture suppressed have also been obtained for the longer distance.

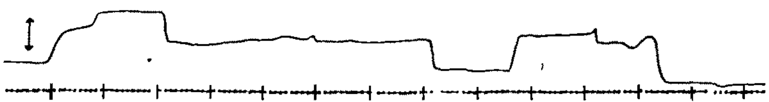

Fig. 1. Up and down right-eye record for subject R. F. V. for binocular fixation of an interlaced picture with considerable action; picture distance, 120 cm. Towards time-line corresponds to an upward movement. Time dots, 50 per sec. Height of arrowed line represents a rotation of 3°, assuming the separation of the centre of curvature of the cornea and the centre of rotation of the eye is 5·3 mm.

The results indicate that, within the limits of sensitivity of the apparatus, there is little difference beween eye movements for sequential and interlaced scan. For both types of scan, eye movements for fixation of the screen in the absence of the picture are similar to fixation eye movements previously reported[2,3]; the movements for the moving target are likewise similar to those previously investigated[4], lthough most subjects experienced 'crawling' for the interlaced scan. For both sequential and interlaced raster, the movements in the presence of a picture appear to depend on the picture content; part of such a record for interlaced scan is shown in Fig. 1.

Gouriet[1] has suggested that, in order to produce loss of interlace, the eye should, in 1/50 sec., move hrough an odd multiple of half the angle subtended by consecutive lines in any interlaced frame. For he smaller viewing distance, this angle is 7′; for the larger viewing distance it is 2′. Such movements would be readily detectable at the shorter viewing distance, since the limit of detection of the photo-electric corneal reflex method[5] is 1′. However, the records show no trace of 50 c./s. movements, although most subjects found the interlaced raster more unstable than the sequential.

This investigation would thus appear to indicate that the instability and 'crawling' associated with interlaced scan cannot be immediately explained in terms of the eye movement pattern.

I am grateful to the B.B.C. Research Department for collaboration in this investigation. I also wish to thank the other subjects, Dr. R. S. Longhurst and Dr. L. C. Thomson, with whom I have had several stimulating discussions. I am grateful to Mr. F. Hodgson for assistance with the recording and to Mr. G. Mallet for construction of the moving pointer. It is a pleasure to acknowledge the continued financial support of the Medical Research Council.

Pre-Columbian Maize in Africa

WHILE accepting the American origin of maize, the question of its existence in Europe before the days of Columbus has been revived by recent archæological finds in Yoruba territory. Goodwin (ref. 1, 13) states that pots decorated by rolling a maize cob over the wet clay have recently been found at Ife. "As vast numbers of specimens were collected from a pavement of potsherds that provided a clear-cut dating line for certain sites, it became important to note whether or not the maize cob decoration occurred. It did, and it is abundantly clear that this particular paving is subsequent to the introduction of maize."

The information now required is: In the reign of what Yoruba king was that pavement laid down, or when did maize reach the Yoruba? Yoruba tradition can at present throw light on the second question but not on the first. Burton (ref. 2, 1, 321) states that maize was introduced among the Yoruba by a yellow-skinned foreigner, who crossed the Niger from the north-east. A historian of the Yoruba, Moore (ref. 3, 4), states that the Kesi were the first to cultivate maize and that their king, Ojoko, decreed that no maize was to be sold to surrounding tribes unless it had been killed for planting by being first soaked in warm water and then dried in the sun.

Babalola (ref. 4, 14) states that the early centre of diffusion of the maize plant among the Yoruba was their original settlement of Ile Ife.

In none of these accounts is there any indication that maize reached the Yoruba from the sea-coast, as would be the case if the Portuguese introduced maize to West Africa.

An attempt will now be made to date these maize-cob decorated potsherds. Burns (ref. 5, 33) states that the first Yoruba capital was at Ile Ife and that during the reign of the fourth king the capital was moved to Oyo. It was while Ile Ife was still the capital that maize, according to Yoruba tradition, reached the Yoruba. Talbot (ref. 6, 1, 278) writes that between A.D. 600 and A.D. 1000, a wave of immigrants from the east invaded the Yoruba and made Ile Ife their capital, but later went to old Oyo. If, now, one takes the latest date for their invasion as, say, A.D. 1000, and that old Oyo was founded c. A.D. 1100, then it would appear that somewhere about this time maize appeared among the Yoruba. No dating much closer than this is at present possible; but what is quite clear is that the dates of the reigns of the Yoruba kings when maize first appeared among the Yoruba far antecedes the arrival of the first Europeans on the Yoruba coasts or the birth of Columbus.

This problem of the presence of maize in western Africa before the days of Columbus can be approached from another angle. My researches show that in Nigeria, as one progresses inland from the coast, the tribal names for maize indicate the route by which it migrated. Thus, the name for maize in tribe *A* is "sorghum of tribe *X*", where *X* is found ultimately to be the name of a tribe east or north of the receiving tribe *A*. Meek (ref. 7, 1, 252, 253, 39) writing of the Hegi, among whom the Kanuri language is widely understood, says that their name for maize is: "The guinea-corn (Sorghum) of the Kanuri", while among the Jukun the name is "the guinea-corn of the Pabir". Among the Yakutare the name is *Ajo Kwona*, or the *Sorghum* of the Kwona, alias Jukun. Among the Hausa the name for maize is *dawar masara*, where *dawa* = *Sorghum* and *Masa* = Egypt.

Here local traditions and maize names hold together and support the Yoruba tradition that maize reached them from the north-east. This confirmation of the Yoruba tradition indicates that the names of the Yoruba kings associated with the first appearance of maize reigned before Columbus was born.

There is also historical evidence to support Yoruba tradition. Monod, Teixeira and Mauny (ref. 8, 137), in their account of Valentin Fernandez's visit to West Africa prior to 1506, report his statement that *milho zaburro* flourished in San Tomé where it was planted for the first time in 1502, having previously been shipped thither from the coast of Guinea. Here is evidence that *milho zaburro* was a well-established crop on the coasts of Guinea before 1502. If *milho zaburro* is maize, then it could not possibly be a well-established crop on the coasts of Guinea if it was first introduced into Spain in 1494, which is the earliest date by which Columbus could have introduced this cereal. It follows that if *milho zaburro* is maize, it must have existed in West Africa long before Columbus.

It is necessary to show that *milho zaburro* is maize. Soares de Sousa (ref. 9, 162), writing in 1587, says: "Dá-se autro-mantimento, em todo o Brazil, natural da mesma tena, a qui os indios chamam *ubatim*, qué é o milho de Guiné, que em Portugal chamam Zaburro . . ." Now *milho de Guiné* is still the name in Brazil for maize. A Portuguese dictionary of to-day gives: *Zaburro*, Indian corn, maize.

The question now arises: Who, then, brought maize to Africa before Columbus was born? My researches over the past seven years have now accumulated sufficient data[10] to establish Arab-Negro contacts with the Americas beginning about A.D. 900.

Non-standard Radio Propagation

Squadron Leader A. G. Sheffield, R.C.A.F. (VE3EB), has reported the following occurrence of non-standard radio propagation observed in Ottawa:

Date	Time (EDT)	Frequency	Location	Remarks
June 23	1900–2030	66–72 Mc./s.	WADS—TV Kansas City (915 n.m.)	Estimated signal up to 200 micro-volts (received on indoor half-wave antenna)
June 24	1300–1400	60–66 Mc./s.	KMA—TV Omaha, Neb. (897 n.m.)	Steady signal with intermittent out of phase components displaced approx. 3 micro-seconds
June 24	1300–1400	66–72 Mc./s.	Not identified	Weak signal, origin unknown

He comments: "During this period, other long-range reception was evident over the frequency range of 54–72 Mc./s., but there was no opportunity for identifying it. Tests were made using a horizontally polarized co-linear antenna array consisting of four dual-stacked elements about 30 ft. above ground; 360° rotation of this antenna, which has a beam-width to 3 db. points of about 10°, did not change the strength or otherwise affect the signals observed. For the duration of this extraordinary long rang very high-frequency reception, normal signals of few microvolts from television stations about 100–18 miles distant could not be obtained".

The Rockcliffe weather office of the Department o Transport has very kindly furnished weather map and an interpretation for the period June 21–25 It appears that the conditions at the time are ver common for the region; these are a weak fronta surface giving a stable layer at about 10,000 ft. fo the period of abnormality together with a surfac inversion at about 1,000 ft. during the nights *Radio-sonde* data are normally available at severa points on or near the path.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, November 23

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. G. L. Bailey: "Alloys" (Cantor Lecture). (Further Lectures on November 30 and December 7.)

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Prof. Frank Debenham: "New Light on Livingstone's Last Journey".

Tuesday, November 24

Communication Research Centre (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. T. B. L. Webster: "Communication of Thought in Ancient Greece".*

Institute of Fuel (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Dr. F. M. H. Taylor: "The Conservation of the Nation's Fuel and Power Resources".*

Society of Public Analysts and Other Analytical Chemists, Physical Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Annual General Meeting; 6.30 p.m.—Dr. J. Haslam: "Physical Methods in the Analysis of Plastic Materials—Some Observations of an Analytical Chemist".

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W.1), at 6.30 p.m.—Mr. R. D. Mylon: "Unusual Aspects of Automatic Control in the Chemical Industry".

Institution of Electrical Engineers, London Students' Section (at Savoy Place, London, W.C.2), at 7 p.m.—Mr. B. Z. de Ferranti: "Machines, Animals and Information".

Tuesday, November 24—Wednesday, November 25

Institution of Gas Engineers (at Church House, Westminster, London, S.W.1), at 9.30 a.m. each day—19th Autumn Research Meeting.

Tuesday, November 24—Thursday, November 26

Iron and Steel Institute (at 4 Grosvenor Gardens, London, S.W.1)—Annual General Meeting followed by Symposium on Sinter.

Wednesday, November 25

British Council for Rehabilitation (in association with the University of Sheffield, Department of Social Medicine, in the University Medical Library), at 10 a.m.—Conference on "Can Disabilities be Overcome?"

Postgraduate Medical School of London (at Ducane Road, Shepherd's Bush, London, W.12), at 2 p.m.—Prof. C. Rimington: "Porphyrin Metabolism".*

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. C. A. P. Southwell: "Kuwait".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Royal Statistical Society, Research Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. F. G. Foster and Mr. A. Stuart: "Distribution-Free Tests in Time Series based on the Breaking of Records".

Institute of Physics, Education Group (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. M. R. Gavin: "Electronics in Physics Courses".

Institution of Electrical Engineers, Supply Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. N. Troost: "A New Approach to the Theory and Operation of Electrostatic Precipitators for Use on Pulverized-Fuel-Fired Boilers".

Society of Chemical Industry, Plastics and Polymer Group (joint meeting with the London Section of the Oil and Colour Chemists' Association, at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. C. R. Hollis and Mr. J. H. W. Turner: "Vinyl Emulsion Polymers and their Use in Coatings".

Thursday, November 26

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. D. A. Sholl: "The Anatomist and the Brain".*

Thursday, November 26—Friday, November 27

Royal Institute of Chemistry (in the Gas Showrooms (Basement), the Town Hall, Manchester), at 10 a.m. each day—Dalton Exhibition on the Measurement, Use and Application of Radioactive Substances.

Friday, November 27

Institute of Metals (at the Royal Institution, Albemarle Street, London, W.1), at 10.30 a.m.—Informal discussion on "The Training of Metallurgists for Industry".

Textile Institute (at 10 Blackfriars Street, Manchester 3), at 3 p.m.—Mr. B. M. Sweers (Arnhem): "Economic Aspects of the Textile Industry in Europe" (Emsley Lecture).

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Geophysical Discussion; Mr. J. Squires, Mr. A. B. Malone, Mr. P. A. Rankin and Dr. S. K. Runcorn: "Airborne Magnetic Surveys". Chairman: Sir Harold Spencer Jones, F.R.S.

Bedson Club (in Lecture Theatre II, The Chemical Laboratories, King's College, Newcastle-upon-Tyne 1), at 5.30 p.m.—Dr. J. R. Kenyon, F.R.S.: "Contributions to Optical Activity to the Study of Some Chemical Reactions".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. R. F. Darling: "Fuel Systems and Controls for Marine Gas Turbines"; Mr. B. H. G. Fowling: "Main Propulsion Gas Turbine Set for the Oil Tanker *Auris*".

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. R. Tomaschek: "The Tides of the Solid Earth and their Geophysical and Geological Significance".* (Further Lecture on November 30.)

Royal Institute of Chemistry (at the Town Hall, Manchester), at 7 p.m.—Sir John Cockcroft, C.B.E., F.R.S.: "The Development of Radiochemistry and Radiation Chemistry" (Eighth Dalton Lecture).

Royal Institute of Chemistry, London Section (joint meeting with the Cambridge University Chemical Society at the University Chemical Laboratory, Cambridge), at 8.30 p.m.—Prof. W. Baker, F.R.S.: "Some Aspects of the Chemistry of Phenols and Inclusion Compounds".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Alexander Fleming, F.R.S.: "Antibiotics".

Saturday, November 28

Botanical Society of the British Isles (in the Lecture Hall, British Museum (Natural History), Cromwell Road, South Kensington, London, S.W.7), at 2.30 p.m.—Annual Exhibition Meeting.

British Glaciological Society (joint meeting with the Scott Polar Research Institute, at the Institute, Lensfield Road, Cambridge), at 8.30 p.m.—Prof. Gordon Manley: "Climatic Fluctuations and the Recent Behaviour of Glaciers".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (with good honours degree, and postgraduate experience in physical chemistry, and suitable teaching experience) in Physical Chemistry, at the Leeds College of Technology—Chief Education Officer, Education Offices, Leeds 1 (November 25).

Research Assistant in Psychology to carry out experimental work in the Department of Psychology—The Registrar, The University, Manchester 13 (November 28).

Senior Scientific Officer (with first- or second-class honours degree in physics or physical chemistry) at theDepartment of Scientific and Industrial Research, Building Research Station, Bucknalls Lane, Garston, near Watford, for work on the flow properties of suspensions—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.278/53A. (November 28).

Assistant (with honours degree in biochemistry, agricultural chemistry or equivalent qualification) in Agricultural Biochemistry—The Secretary, The University, Aberdeen (November 30)

Physical Chemist or Biochemist (with research experience in the fields of enzyme or protein chemistry) in the Department of Medicine, to work under the direction of the newly appointed Nuffield Gerontological Fellow—The Registrar, The University, Leeds 2 (November 30).

Analyst (with degree in chemistry or agricultural chemistry, and with experience in carrying out analyses on soils, fertilizers and other agricultural materials) in the Department of Chemistry—The Registrar, Wye College, Ashford, Kent (December 5)

Lecturer in Psychology at the University of Durham—The Secretary, 38 North Bailey, Durham (December 5).

Lecturer in Textile Physics in the Department of Textile Industries, to undertake research on the structure and physical properties of fibres and related materials, using X-ray, electron microscope, ultra-centrifuge and infra-red techniques—The Registrar, The University, Leeds 2 (December 7).

Chief of the Division of Animal Health and Production, Commonwealth Scientific and Industrial Research Organization, Australia, to be responsible for research activities in the fields of animal physiology, animal breeding, bacteriology, pathology and parasitology—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 200/31 (December 12).

Research Officer (Organic Chemist) (with honours degree in science or equivalent qualifications, and research experience in organic chemistry) at the Commonwealth Scientific and Industrial Research Organization, Wool Textile Research Laboratory, Parkville, Melbourne, to participate in an intensive programme of research on the structure of wool as a member of a group engaged in the synthesis of peptides, especially cystine peptides—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 464/72 (December 12).

Research Officers (*a*) (with university honours degree in science, with chemistry as a major subject, or equivalent qualifications) to undertake physico-chemical studies of systems of importance in the utilization and chemical processing of minerals and their derivatives (Ref. 590/460); (*b*) (with university honours degree in science, with inorganic or physical chemistry as a major subject) to undertake general investigations on chemical derivatives of certain Australian minerals (Ref. 590/461), at the Commonwealth Scientific and Industrial Research Organization, Minerals Utilization Section, Division of Industrial Chemistry, Fishermen's Bend, Melbourne—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2 (quoting appropriate Ref. No.) (December 12).

Lecturer in Geography (Grade 1), and a Lecturer in Mathematics (Grade 1), at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (December 15).

PROFESSOR OF PHYSICS—The Secretary and Registrar, University College of North Wales, Bangor (December 15).

CHAIR OF PHARMACOLOGY AND THERAPEUTICS—The Registrar, The University, Sheffield 10 (January 1).

RESEARCH ASSISTANT IN THE FLUID MOTION LABORATORY, to carry out experimental research on the aerodynamic noise generated by turbulent flows—The Registrar, The University, Manchester 13 (January 1).

SIR THOMAS LYLE FELLOWSHIP IN PHYSICS at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 4).

ASSISTANT, Grade B (with good honours degree in chemistry and able to teach organic chemistry to final degree standard)—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham, Essex.

ASSISTANT LECTURER (Grade A) IN PHYSICS—The Principal, Borough Polytechnic, Borough Road, London, S.E.1.

BIOCHEMIST (with first- or second-class honours degree in biochemistry, biology or chemistry, and substantial experience in isolation of pure substances from biological materials) at the Ministry of Supply Radiochemical Centre, Amersham, Bucks, to take charge of group engaged in developing biological methods for synthesis of compounds containing carbon-14 and other radioactive isotopes—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.582/53A.

DEMONSTRATOR, ASSISTANT LECTURER or LECTURER IN THE DEPARTMENT OF PHYSICS—The Secretary and Registrar, The University, Southampton.

DIRECTOR (with first- or good second-class honours degree in a pure science and considerable postgraduate experience in microbiological research) OF THE COLONIAL MICROBIOLOGICAL RESEARCH INSTITUTE, Trinidad—Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.87/28/01.

GRADUATE IN PHYSICS to assist in research in space and water heating section—The Director, The Electrical Research Association, 5 Wadsworth Road, Greenford, Middlesex.

LECTURER or ASSISTANT LECTURER IN ANIMAL PHYSIOLOGY in the Department of Zoology—The Secretary and Registrar, The University, Southampton.

PHYSICAL CHEMIST (preferably Ph.D.) for research work on the kinetics of cellulose degradation—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester.

PHYSICAL CHEMIST (with good honours degree) for research on wool fibres and problems related to wool processing, especially detergency—The Wool Industries Research Association, Torridon, Headingley, Leeds 6.

PLANT PATHOLOGISTS (2) (with first- or second-class honours degree, and preferably with two years or more postgraduate experience) in H.M. Colonial Service, West Africa, to work on the control of plant diseases by the use of fungicides—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE. 87/14/01.

RESEARCH ASSISTANT (with good honours degree in zoology and interested in vertebrate anatomy and embryology) IN MAMMALIAN GENETICS—The Secretary, University College, Gower Street, London, W.C.1.

RESEARCH ASSISTANT (with honours degree in physics or engineering) to the Principal of the College, to carry out research into the physical principles of the woollen textile processes—The Principal, Scottish Woollen Technical College, Galashiels, Selkirkshire.

SCIENTIFIC OFFICERS (with first- or second-class honours degree or equivalent in mathematics or physics) for operational research on a wide variety of problems, in London and the provinces, under the direction of the Scientific Adviser to the Air Ministry—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W 1, quoting A.285/52A.

TECHNICAL ASSISTANT (graduate in mathematical and/or physical science, and a good knowledge of at least one modern continental language, preferably German) IN THE SCHOOL OF THEORETICAL PHYSICS, for duties which will include scientific, secretarial and library work—The Registrar, Dublin Institute for Advanced Studies, Dublin.

UTILIZATION OFFICER (with degree in forestry and experience in timber exploitation and saw-milling operations) IN THE FORESTRY DEPARTMENT, Gold Coast Local Civil Service, to conduct detailed investigations into the resources and potential uses of local timber, and to advise on extraction and conversion methods and improvement of timber seasoning and grading—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.61/13/04.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Report of the Thirteenth International Horticultural Congress, 1952; London, 8–15 September. 2 volumes. Vol. 1: Pp. xv+576+39 plates. Vol. 2: Pp. viii+577–1297+plates 40–100. (London: Royal Horticultural Society, 1953.) Two volumes 42*s*. [169

British Productivity Council. Productivity Report: Fuel Conservation. Report of a visit to the U.S.A. in 1952 of a specialist team on the Conservation of Fuel, Heat and Energy. Pp. xii+102+8 plates. (London: British Productivity Council; Washington, D.C.: Office of Technical Services, Dept. of Commerce, 1953.) 5*s*. [179

Memoirs of the Royal Astronomical Society. New General Catalogue of Nebulæ and Clusters of Stars (1888); Index Catalogue (1895); Second Index Catalogue (1908). By Dr. J. L. E. Dreyer. Pp. iv+378. (London: Royal Astronomical Society, 1953.) 70*s*. (50*s*. to fellows.) [179

Cocoa: a Crop with a Future. By Paul Bareau. Pp. 39. (Bournville: Cadbury Brothers, Ltd., 1953.) 7*s*. 6*d*. [179

SCIENCE IN AUSTRALIA

THE visit of H.M. the Queen and the Duke of Edinburgh to Australia is a good occasion for British scientists to consider the short history of science in that country; for it is an exciting history and instructive in many ways. It is only 174 years since Joseph Banks proposed to a committee of the House of Commons that a colony might be established in Australia, to offset some of the embarrassments which the War of American Independence was causing in England; and it is only 165 years since Captain Phillip entered Port Jackson and settled with 717 convicts, 18 officers and 191 marines on the low rocky shores of Sydney Cove. Under such unpromising conditions the Commonwealth of Australia was born. While Captain Phillip and his staff were tentatively exploring the rocky forests and scrub which surround Port Jackson, James Hutton in Scotland published his "Theory of the Earth", Henry Cavendish was reading papers to the Royal Society, and William Smith was setting to work on his geological map of Britain. It would have needed a bold prophet to predict at that time that in five generations Australia would occupy a high and honourable place in world scholarship.

How has this impressive transformation occurred? The critical move was made about a century ago, when the citizens of Sydney and Melbourne each made a decision which turned their colonies from mere military and trading centres into the mainstream of civilization. In both cities universities were founded: the University of Sydney in 1850 and the University of Melbourne in 1853; and this happened at a time when there were only four universities in England and none in Wales. There was no meanness about the foundations. At a time when the University of Sydney had less than a hundred students, a hall and quadrangle were built there which would not look out of place in the Broad at Oxford, and the university buildings at Melbourne, if less impressive, are no less dignified. Adelaide and Tasmania followed suit. At the turn of the century Australia had four universities; it now has eight—including one postgraduate university—for a population considerably smaller than that of Scotland; and one student in about 270 of the population compared with one student in about 550 of the population in Britain. Until comparatively recently these universities were the only centres for science and scholarship in Australia. Once the initial enthusiasm had waned they were not well financed, and they had therefore to economize in the only way universities can—by having too few teachers; and this in turn hampered research. But they gave a sound training to undergraduates and sent many young men to complete their scientific apprenticeship in Britain. Besides the universities there were the State Departments of Agriculture; but these were of necessity concerned with short-term projects. Their staffs worked under constant pressure to solve day-to-day problems, and naturally they became more expert in applying science to practice than in extending the frontiers of science itself.

In 1900 the colonies of Australia coalesced to form the Commonwealth. The pattern of this inevitable but long-delayed development has had a profound effect on science in Australia; for the States retained many powers which (to an outside observer) would have been better handed over to the central government. For example, agriculture and forests remained the concern of the States; so did minerals and artesian water; so did education: and by and large State policy was narrower, more parochial, less far-sighted than Federal policy, and certainly not so well financed. Some of the consequences of this were serious to science. There was at the outbreak of war in 1939 no Federal geological survey, no Federal control of forestry, and no Federal aid to education; and in none of these fields did the States consider it was worth while to spend much money on research.

Australia's scientific life was saved by the Council for Scientific and Industrial Research, set up in 1926 under the Federal Government. It began as a modest organization to do long-range research into problems of primary production. By the time the War had ended and the C.S.I.R. was twenty years old, it had become one of the largest and most distinguished scientific organizations in the world. Its annual budget ran into six figures. Its divisions covered not only agriculture but also radiophysics, food technology, fisheries and industrial chemistry. Its policy was to give its staff the maximum freedom to do long-range research even though it might offer no immediate prospect of benefit to Australian agriculture or industry. The wisdom of this policy has been abundantly demonstrated. Improved yields in crops and wool and meat alone must have paid many times over for the whole cost of running the Council since 1926. A survey of its work during 1951–52 appears on p. 978.

The architect of this scientific organization is Sir David Rivett, who left the chair of chemistry in Melbourne to become its chief executive officer. It must have given him deep satisfaction to come from his retirement and take the chair, in July 1951, at a seminar called "Science in Australia", on the occasion of the fiftieth anniversary of the founding of the Commonwealth. The proceedings of that seminar have recently been published[1]. They contain addresses on the contemporary state of various sciences in Australia and a discussion on "A Scientific Policy for Australia". The addresses contain none of the complacency which the British (still deplorably out of touch with life in the Commonwealth) sometimes associate with their cousins in the southern hemisphere; indeed, some of them are refreshingly self-critical. There is only a pardonable minimum of self-congratulation; and it is abundantly clear that the Australian scientist is aware of the shortcomings of science in Australia and is resolved to overcome them.

For shortcomings there undoubtedly are. The most serious of them is a by-product of the very success of the C.S.I.R.; for the Council has so fostered fundamental research that it now has a near-monopoly of it. It is, of course, easy enough to improve on history after the event; but one cannot avoid the conclusion that if twenty-five years ago the Council had adopted a policy of co-operation with the universities, science in Australia would rest on much firmer foundations than it in fact does. Looking back on those days, one now realizes that the prime function of the Council was to establish a tradition for scientific research. The universities were doing very little. The State Governments were doing none. The Council had a choice of two ways of accomplishing its function. The quick way was to isolate itself from the universities with their swollen student populations, and from the States with their restrictive obligations to do remedial work for agriculture and industry, and to set up teams of research workers under good conditions in separate institutes. The slow way was to realize that good science can be done only by well-trained men, and accordingly to put resources into the universities, building up research units (as the Agricultural Research Council does in Britain) in close proximity to undergraduates. The Council for Scientific and Industrial Research chose the quick way. The result of this choice is that science in universities has been weakened by the Council, not strengthened; and as a consequence the training of scientists is incommensurate with the demand. The mere 'planting' of a C.S.I.R. Division near a university department (as has happened with the Soils Division in Adelaide and the Radio-Physics Division in Sydney) merely exacerbates the inequality of opportunity for research of a university lecturer compared with a C.S.I.R. officer. A more intimate integration of research and teaching was needed, and the continued absence of this led to the opinion (perhaps unjustified) among the universities that they had been 'let down' by the Council; at any rate, the Council has certainly suffered some embarrassment in recruiting Australian graduates, due directly to its long enjoyment of a monopoly in scientific research. In justice to the Commonwealth Scientific and Industrial Research Organization (C.S.I.R.O.), which is the new administrative form of the Council, it must be emphasized that a great effort is being made to repair these earlier omissions. In Sydney and elsewhere, units of the Organization are established in university departments, and they share in the teaching and in the direction of research.

A second shortcoming of science in Australia is that many of the large industrial firms have their headquarters in Britain and do all their important research there. Consequently, there is no body of industrial research in Australia to match its astonishingly rapid development of industry. As the writer of the introduction to "Science in Australia" says, "very few of the major companies, which are now well established, have paid more than lip service to research activities". This circumstance reflects upon science in universities, too; for the bright industrial scientist is impelled to look to the United Kingdom for a good job.

Finally, there is an impediment, rather than a shortcoming, to the development of science in Australia which it is our business in Britain to remove; and it is high time we removed it. The first-class Australian graduate has no sooner taken off his gown at the graduation ceremony than he has his eyes on the sailing lists for Britain; and by one means or another most first-class science graduates manage to get to Britain. This is due to a combination of sentiment for 'home' and admiration for British science; and it is altogether admirable. But it is depressing for the Sydney or Melbourne professor who is trying to build up a research school. The time has come when exports of brains should be more nearly balanced by imports: for Australia has great opportunities to offer British graduates, especially in biology, geology, geography and anthropology. In equipment and laboratories its universities compare favourably with most in Britain. There is (contrary to the assertion of one speaker at the seminar) a new spirit of *esprit de corps* among scientists in Australia; and it is an invaluable experience for a young man to put in some years of research and teaching in the Commonwealth. On p. 132 of "Science in Australia" there is a rueful table complaining that only 30 per cent of lecturers in Australian universities have had overseas training. Is it too much to hope that the time may come when we in Britain criticize ourselves because only 30 per cent of our university lecturers have Commonwealth experience? This is no capricious musing. Upon that hope being fulfilled may depend the stability of the British Commonwealth.

BIRDS OF SCOTLAND

The Birds of Scotland

Their History, Distribution and Migration. By Evelyn V. Baxter and Leonora Jeffrey Rintoul. Vol. 1. Pp. liii+352+12 plates. Vol. 2. Pp. 353–763+14 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1953.) 63*s*. net.

THIS magnificent work, in two volumes, forms an outstanding contribution to the ornithology of the British Isles, and especially of Scotland. Both the authors are well-known personalities and life-long students of ornithology: they have watched and observed together for many years. Just as the work was published the sorrowful news was announced of the death of one of the authors—Miss L. J. Rintoul.

The information in the books is accurate and scholarly: it embraces records old and new, and painstaking research must have been needed to have gathered them together. It is not too much to say that this will be the standard work on Scottish ornithology for many years to come.

In the first volume there are chapters on Scotland, the factors which influence the bird life, the composition of Scottish avifauna, and migration. Next there is a description of the birds themselves, beginning with the Corvidæ, the first bird described being the raven.

The second volume begins with the swans and ends with the partridge. Each bird is sympathetically described: its past and present distribution are set down in detail, and the reader is thus given a clear picture of the species. Both volumes are packed full of interesting information. In the chapter on migration the importance of the bird-watching stations at Fair Isle and the Isle of May is pointed out. Among rare migrants to Scotland are the rock thrush, a brilliantly plumaged bird which nests no nearer than central France, the white-spotted bluethroat, the sub-alpine warbler, the dusky warbler, the pied wheatear, and (once) the needle-tailed swift.

One of the most sedentary birds, the crested tit, has long had its headquarters in the forests of natural Scots fir on the upper reaches of the Spey. It is remarkable, therefore, that it does not seem ever to have crossed the passes of the Cairngorm Hills until recent years and was unknown in the Forest of Mar, although the distance between the two forests is no more than fifteen miles. It is interesting how quickly a species can re-establish itself. The stonechat, which was entirely wiped out by the severe weather in the Isle of Skye in the early months of 1947, has now (1953) reappeared in precisely its old haunts. There is unusual information even of common birds. Who, for example, knows that a robin once visited the Observatory on Ben Nevis (4,406 ft. above sea-level) and that on April 12, 1925, another was found dead on the snow at the Pools of Dee, nearly 3,000 ft. above sea-level?

The authors think (Vol. 1, p. 237) that tarmac roads are connected with the decrease of the house martin in Scotland, and point to the fact that the cliff colonies (independent of road mud for their nests) maintain their numbers, whereas the house colonies have decreased. They record (p. 241) that thirty-six house martins on migration over Fair Isle roosted in the crevice of the rock, tightly packed one on top of the other. The record of a swift nesting on Lochnagar (3,768 ft.) is given in the book; I have sometimes doubted the accuracy of this record. Swifts often visit the Lochnagar precipices, but my own impression is that insect life is too uncertain for them to nest thus high. In the Swiss Alps I have seen swifts prospecting crevices at 7,300 ft. high, but they do not nest at that height. On p. 308 the increase of the buzzard in the Outer Hebrides is mentioned. That increase seems to have caused the hen harrier to disappear from its haunts here.

On p. 365 of Vol. 2 the valuable suggestion is made, to account for the disquieting decrease in the numbers of Bewick's swans as winter visitors to Scotland, that the species now winters in Holland in very much larger numbers than formerly. A great dam has caused the Zuyder Zee to become a vast and shallow freshwater lake, and several thousand Bewick's swans habitually winter here, feeding on the *Potamogeton* weed, which has established itself and spread. The record (Vol. 2, p. 467) of a gannet being killed on a wire fence at 2,300 ft. above Loch Hourn in western Inverness-shire makes me wonder whether there may be an occasional flight-line across Scotland from east to west in that district, for in mid-July 1952 I was astonished to see a gannet near Cluanie, at a height of 1,400 ft. above sea-level, gaining height in spirals preparatory to crossing the high hills in the direction of Loch Hourn. Yet the gannet is supposed never to be happy except when flying above the sea. The account of the northern golden plover, which has not been recorded as nesting in Scotland, reminds me that in 1925, on the Western Cairngorms, my wife and I began the construction of a hide at a golden plover's nest at 3,000 ft. The bird, very black in the breast, was, I believe, a northern golden plover; but mist and bad weather prevented us from completing the hide, or photographing the bird to obtain records of it. The description (Vol. 2, p. 731) of the ptarmigan recalls that a few years before the Second World War the late Col. Balfour, of Dawyck, set ptarmigan eggs below a grouse on high ground on Upper Tweed, and the Duchess of Montrose made the same experiment on Goat Fell on Arran, where the ptarmigan at one time nested. Neither experiment was, I think, successful.

The two volumes are handsomely produced. There are two beautiful coloured frontispieces by G. E. Lodge and excellent photographs by Robert M. Adam, Eric Hosking and others.

No student of birds can afford to be without this work. SETON GORDON

CHEMISTRY OF STARCH

Starch and its Derivatives

By J. A. Radley. (Monographs on Applied Chemistry, Vol. 11.) Third edition, revised. Vol. 1. Pp. xi+510. (London: Chapman and Hall, Ltd., 1953.) 65*s*. net.

THE appearance of a third edition of this monograph indicates that its usefulness is well established. Considerable advances have been made in starch chemistry since the second edition appeared in 1943, and this has necessitated large sections of the book being rewritten. The author has, furthermore, invited a number of distinguished collaborators —including several from the United States—to write the chapters in their own specialized fields of investigation. The subject-matter covered has thus been expanded while at the same time an authoritative point of view has been maintained; but two volumes now replace the original one.

As in previous editions, both fundamental and technical aspects of starch chemistry are covered. The general method of presentation has been retained. Each chapter tends to be a review article and there is inevitably some overlapping, although the book presents a uniform appearance. The list of references accompanying each chapter covers the literature to about the end of 1950.

The first volume is divided into two parts, of which the first deals with the structure, properties and reactions of starch, while the second covers amylases and their action. After a short historical introduction, there is an account by S. Peat of the enzymes involved in the synthesis and degradation of starch. This complex field is presented in a clear and concise manner. The fundamental chemical evidence for the structure of starch and its components is summarized in an excellent chapter by L. Hough and J. K. N. Jones. Physical properties such as swelling and gelatinization are also reviewed, with an emphasis on technical aspects. The longest and most complete chapter in the book is that on the starch fractions by T. J. Schoch. This provides a critical review of recent methods for separating, purifying and characterizing amylose and amylopectin. Many useful experimental data are incorporated. The physical properties of the two fractions are also discussed. In addition to an unusually long list of references (437, with the titles of the papers included) a cross-index of subjects is given. The significance of nitrogen and phosphorus in interpreting the behaviour of starch is next discussed; but little recent work is mentioned. An interesting account (by R. L. Whistler) of the phenomenon of retrogradation follows. A chapter discussing the hydrogen-bond by G. V. Caesar is followed by a review of the starch–iodine reaction. R. M. Hixon and B. Brimhall have written a chapter which reviews for the first time the chemistry of the waxy-cereals and starches.

The remainder of the first part deals with more technical aspects of starch chemistry. After a review on dextrins and dextrinization (G. V. Caesar), a comprehensive account is given by E. F. Degering of the preparation and physical and mechanical properties of the ethers and esters of starch. Inorganic and oxidized derivatives of starch are discussed by the same author. In Part 2, the preparation and mode of action of the amylases used in the starch industry are reviewed in a comprehensive manner with emphasis on the technical aspects.

The first volume of the new edition can be seen to incorporate much interesting new material, and should appeal to both the academic and industrial worker with an interest in starch chemistry.

E. L. HIRST

CULTURAL ANTHROPOLOGY

The Nature of Culture

By A. L. Kroeber. Pp. x+438. (Chicago: University of Chicago Press; London: Cambridge University Press, 1952.) 49*s*. net.

MAN can be viewed, as Prof. C. Lévi-Strauss has recently pointed out, either as a tool-making animal or as a social animal. In dealing with primitive man, one's view on this matter determines whether one is a cultural anthropologist (the predominant school in the United States) or a social anthropologist (foremost in Britain).

Prof. A. L. Kroeber, the doyen of American anthropologists, over half a century ago placed himself firmly among those who regard man's tool-making capacities as the basis for a scientific study of mankind. Since then, his copious, but always scholarly and polished, writings have added immeasurably to all the various fields of anthropology, but particularly to the idea of culture. Anthropology without Kroeber would be the poorer; cultural anthropology without Kroeber would indeed be poverty-stricken.

The present book is Prof. Kroeber's own editing of fifty of his articles and essays (some of them pared of extraneous material) centring around the notion of culture; each essay is accompanied by short "programme notes" of the circumstances of its composition, and the author's assessment as of late 1951. The essays are grouped into five sections of which the first and the last, "Theory of Culture" and "History and Process of Civilization", are of greatest general interest. The other three sections—"Kinship and Social Structure", "On American Indians", and "Psychologically Slanted"—are of equally great interest to the professional reader, but probably of less to the non-anthropologist.

Prof. Kroeber's appointed task has been the conceptual separation of culture from the organism, the psyche and society. Culture, to him, is "superorganic". Just as reducing organic phenomena to inorganic terms tells us a great deal about them, but makes us lose sight of the all-important idea of 'life', so reducing cultural phenomena to organic or psychological factors tells us a great deal about them, but makes us lose sight of their equally important and illuminating aspects which are specifically cultural. To watch this idea develop from the outcry of 1917 ("The Superorganic") against the followers of Herbert Spencer who see cultural evolution as a continuation of biological evolution, to the long, thoughtful article of 1949 ("The Concept of Culture in Science") is to follow the development of one of the most provocative ideas of our day.

The section about history and process begins with the famous (1919) article on fashion, containing the germ of his subsequent idea of "styles", which develops into the notions of cultural intensity and climax which underlay his greatest work, "Configurations of Culture Growth". This concept of "styles" is turned and tended until it replaces to some extent the more atomically conceived "culture elements" and "culture traits" as the components, or bits, of culture. All these various threads are brought together in a short, final article dealing tantalizingly, if not exhaustively, with "The Novel in Asia and Europe".

Prof. Kroeber points out that, like all great ideas, the concept of culture was developed by many minds; we must add that one of the greatest and most stimulating of these minds is his own.

PAUL BOHANNAN

ENGINEERING MECHANICS

Mechanics

Part 2: Dynamics. By Prof. J. L. Meriam. Pp. xiii+341–671. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1952.) 32*s.* net.

THIS elementary work on dynamics is essentially a book for engineers. Its author's aim is to teach fundamentals with the aid of a large number of illustrative examples.

The book starts with prefaces addressed to (*a*) the student and (*b*) the instructor. The latter, with its discussion of the "natural learning process", should undoubtedly be read aloud with an American accent.

The introductory chapter, which is evidently common to Prof. Meriam's volumes on statics and dynamics, concerns certain fundamental ideas. These include mathematical and graphical description, "basic concepts" (space, time, force, etc.), scalars and vectors, Newton's laws, units, dimensions, accuracy and so forth. The author's intention is to build an arsenal of what information he considers necessary for the assault on his subject. But his choice seems a little ill-balanced. Some parts of his introduction read like a sermon (for example, that on graphical representation) while others appear to be rather difficult for a beginner (for example, that on dimensions).

Apart from this introduction, the book contains chapters entitled "Kinematics"; "Principles of Kinetics"; "Force, Mass and Acceleration"; "Work and Energy"; "Impulse and Momentum"; "Periodic Motion". The treatment of these subjects is simple and, although vector quantities are mentioned, the methods of vector analysis are not used to any great extent.

All the chapters except the introduction embody a large number of problems, some of which are worked out in the text. Answers are given to many. There are 662 of these examples (in a book of 330 pages) and most of them are well drawn from practical situations. It is the reviewer's opinion that these problems constitute a most attractive feature. There are two appendixes. The first deals with moments of inertia (and contains no fewer than seventy-two examples) and the second is a useful collection of data.

One or two topics are introduced which have not found their way into many comparable books. Cases in point are (1) the use of polar co-ordinates, and (2) motion "with variable mass". Both are undeniably welcome. Elementary gyroscope theory is introduced in the chapter on impulse and momentum and involves the use of vectors. It is unfortunate that, in a book which deals with Coriolis acceleration, no attempt is made to explain gyro theory after the manner of Inglis.

The collection of examples is excellent, and it alone would make this book a worth-while contribution. The main body of the text is of good quality. It is lucid and contains a large number of helpful diagrams.

R. E. D. BISHOP

ELEMENTARY ANIMAL ECOLOGY

Animal Ecology

By W. H. Dowdeswell. Pp. xv+208+16 plates. (London: Methuen and Co., Ltd., 1952.) 12*s.* 6*d.*

ALTHOUGH the subject of plant ecology has been reasonably well covered at different levels in a number of books, the subject of animal ecology has not received the same attention by authors, especially at the elementary level. This, in its turn, has contributed to the comparative neglect of the subject in schools. In this book, the senior biology master at Winchester College has sought to remedy the deficiency by providing a broad introduction to the ecology of animals which will not only cater for existing needs but will also stimulate further interest in animal ecology among sixth-form students in schools and first-year students at universities.

After a description of the range and purpose of animal ecology, the author examines the distribution of animals resulting from changing environment, colonization, isolation, specialization and seasonal change. Then follows an account of some general features of animal communities with particular reference to periods of activity and rest, food relationships and food chains, ecological niches, the size of animal populations, and animal movements. This is succeeded by examination of special animal forms like parasites, commensals and symbionts. Up to this point the book follows along stereotyped lines, its main virtue being that much of the information which is already available in students' text-books is here collected together to form a connected introduction to animal ecology.

The remainder of the book is made up of descriptions of animal communities including land, marine, estuarine and freshwater. For these the author can be warmly commended for accounts which will quicken interest in animal ecology among students who are just beginning their studies of the subject. They will receive some help from the chapter on practical animal ecology but would have profited even more if the author had omitted his trivial introduction to statistics and included some accounts of practical ecological studies which his own sixth-form students had carried out as well as suggestions for practical work of an experimental nature.

The book contains a useful bibliography and is illustrated with well-reproduced half-tone plates and line drawings.

T. H. HAWKINS

PROVISIONING EXPEDITIONS IN THE FIELD

SIR EDWARD MELLANBY opened a symposium, which had been arranged jointly by the Nutrition and Geographical Societies and was held on October 26, dealing with the provisioning of expeditions in the field. Sir Edward recalled the evolution of his own interest in this subject from that of the domain of pure science to the more humble but perhaps more practical realm of packaging!

The first paper, on emergency rations, was given jointly by Dr. G. R. Hervey and Prof. R. A. McCance and mainly concerned survival at sea. The authors have approached the problem from the physiological point of view. Even under the best conditions, a man requires at least one litre of water per day. Since he only has about forty-two litres of water in his body, and may be in a very bad way after losing seven litres, survival without water has a very definite time-limit. Food is much less important than water, except for its value for morale, for a man can live on his own tissues for weeks; indeed, food might be dispensed with altogether were it not for the fact that a small, relatively salt-free ration containing a little carbohydrate could materially reduce the output of salt and the destruction of tissue protein, and consequently for both reasons the volume of the urine and the water requirements.

Prof. McCance outlined a desirable, a compromise, and a minimum ration based upon water, boiled sweets, toffee, condensed milk and special biscuits. In practice, the rations necessary for the equipment of a life-raft must depend upon the length of time for which they are likely to be required, and the allowance of water, particularly, must be varied with the climatic conditions likely to be encountered. He concluded with a brief description of the new inflatable tented rafts which are being developed by the Navy, and pointed out that in them a man could create his own environment so that he could keep himself cool enough in the tropics to maintain his losses of water at or about the theoretical minimum, and survive in cold climates where he would die of cold and exposure in an open lifeboat.

Dr. H. G. Smith dealt with Army operational rations. These, he said, have now been standardized into five main packings, of which four differ only in respect to the number of men and the length of time for which they are designed. The fifth is an emergency ration consisting of four slabs of chocolate providing 860 calories. The principle in the Army is to give a soldier operational rations which rival the food he gets at the base camp; four of the rations supply two main meals and a snack meal, providing 3,000–4,250 calories a day. The food is packed in cans which only need heating. A ration consisting of bully beef and biscuits is a thing of the past.

With the increasing range of aircraft there is no means of telling whether an aircraft is likely to crash on land or sea, and Squadron Leader D. G. V. Whittingham pointed out that the rations required in the two cases are very different. The Royal Air Force emergency rations, which are carried under the ejector seat, are reckoned to be of less importance than the parachute, the dinghy, and wireless apparatus to facilitate location and rescue. Water is the prime consideration at sea and in the desert, and since the R.A.F. has to cover all climates and eventualities, the rations are carried in two parts. The "Universal Component" consists mainly of carbohydrate, and the "Land Mass Supplement" provides extra calories for a man travelling over land and perhaps requiring much exertion; this includes foods providing fat and protein as well as carbohydrate. It is assumed that water will be available for men who are using this supplement. Recent experiments suggest that such a ration may contain a high proportion of fat, so giving maximum calories for weight, and even if this leads to ketosis, this does not progress after the first few days and does not cause an appreciable degeneration in physical or mental performance.

The discussion was opened by Miss D. F. Hollingsworth, who described the products of the Ministry of Food's experimental plant for drying foods at Aberdeen. She was followed by Dr. A. Bombard, who made several interesting points on the basis of his practical experiences in crossing the Atlantic alone in an open craft. One was that survival at sea depends upon the will to survive more than anything else, and another was that although he had drunk sea water for the first few days of his voyage he would have died long since of this dangerous practice if he had done what had been attributed to him by the Press. His main concern had been to demonstrate the possibility of survival given no emergency rations at all. By spearing fish with a pen-knife, and drinking the juice, it was possible to survive for long periods of time, even if no food had been placed in the raft; but it had been the collection of rain water which had enabled him to survive his voyage across the Atlantic.

A lively discussion followed on the palatability (or otherwise) of dehydrated foods, and the meeting then adjourned for some practical nutrition in the shape of tea.

Prof. B. S. Platt was unfortunately ill, and Dr. R. H. Fox read the joint paper by himself and Prof. Platt on planning food supplies for tropical expeditions. Stability of body temperature in the tropics can only be maintained by sweating, and water requirements are high, but water can usually be obtained. Dr. Fox illustrated these physiological points by a diagram showing the various factors which contribute to thermal balance. He believes that in spite of its specific dynamic action, the diets should contain some protein to help to promote appetite, which is often rather poor in the tropics, even if men are working hard. Likes and dislikes are all-important in designing rations for a tropical expedition, because people tend to go without food when suffering discomfort from heat, rather than eat what they do not like.

Dr. L. G. C. E. Pugh opened his talk on nutritional aspects of Himalayan mountaineering by a description of the experimental work which has led to the belief that a high carbohydrate diet increases a man's tolerance to great altitudes, and supported this by the experiences of people on earlier expeditions to great heights. In earlier Everest expeditions, climbers took an enormous store of luxury foods such as chicken in aspic; but they found when they got high up that they wanted something more ordinary, and often relied mainly on sugar and other carbohydrate foods. In general, diets have tended to get simpler and simpler, and local foods have been used extensively on some expeditions. In Dr. Pugh's opinion, however, curry and tea were overdone on the Cho Oyu expedition! He emphasized the importance of labelling the packages of foods clearly so that the climbers do not find themselves with nothing but potatoes to eat for several days on end—as once happened, and which he thought, with good reason, did not improve morale. On the recent Everest expedition, the average calorie consumption was 4,300 a day during the approach march and 3,900 at 19–22,000 ft. The food was all taken out from Britain, and it was packed in such a way as to make up seven different menus, each box being labelled with a day of the week. This proved to be a very successful arrangement right up to the Western Cwm. At very high altitudes men generally prefer carbohydrate above all else, and on this expedition the climbers were provided with 14 oz. of sugar a day and readily ate it. Special fancies were catered for, however, and on the final assault Hillary chose to eat sardines and biscuits. The loss of water from the lungs at high altitudes is four times as great as it is at sea-level, and Dr. Pugh emphasized the importance of an adequate supply of water. He pointed out that one of the causes of failure of some previous expeditions, the Swiss one for example, was lack of water. This year, better stoves and more fuel were taken to melt the snow, and the physiological degree of hydration had been virtually maintained.

Dr. G. C. L. Bertram dealt with the evolution of polar rations. Polar rations have always tended to be of the simplest type and appear very spartan and monotonous when compared with the rations which the Army sets out to provide to-day. Bertram emphasized that there has been some tendency in recent years to increase the number and variety of items carried on sledging journeys; but he considers that this is really unnecessary and that raising the standards of sledging rations tends to lead to dissatisfaction. Men who voluntarily undertake polar work, and who are working in a cold climate, can live on the simplest food day after day and enjoy it. He suggested that the importance of individual variation in calorie requirements is not generally appreciated; but there are psychological reasons for not differentiating between the big and small eater on these expeditions. It could, however, be satisfactorily done by issuing a supplement which would vary with the loss of weight. The fat content of the sledging ration is generally very high, and men may not like it for the first few days, but they soon get used to it. When expeditions relied upon human transport the weight of food carried for the men was a very important matter; but since the general adoption of dog transport, and still more recently of mechanical motor transport, the weight of the food required for the men has become less and less important because of the large amounts of food or fuel necessary for the dogs or tractors. For example, on a normal sledging expedition the ratio of the weight of the dogs' food to the men's food is 4–1, and a ratio of fuel to food on a tractor expedition would be even higher.

These papers were followed by a short discussion on the apparent difference between men's reaction to food in the tropics or at high altitudes as against polar regions. In the two former, they prefer to have nothing rather than eat what they dislike, even though they should be hungry; in extreme cold at sea-level, hungry men will eat anything. In spite of its taste and the difficulty some people find in getting it down, yeast was recommended by one speaker as a promoter of appetite, and the suggestion was made that it should be supplied at high altitudes. In an attempt to explain away the gargantuan appetite of the polar explorer, Bertram then rose and made the point that all polar rations now include yeast, and Mr. A. L. Bacharach brought the discussion to an end by remarking that in his experience a man who could eat yeast could eat anything.

MECHANISM OF PHOSPHORYLATION IN THE RESPIRATORY CHAIN

By DR. E. C. SLATER
Molteno Institute, University of Cambridge

WHEN Belitzer and Tsibakowa[1] and Ochoa[2] found that more than one atom of phosphorus was esterified for each atom of oxygen consumed by respiring tissue preparations, they suggested that the phosphorylation must occur not only when the substrate was dehydrogenated, but also during the passage of the hydrogen atoms over the intermediate carriers to oxygen. This was demonstrated experimentally by Lehninger[3], who showed that phosphorylation accompanied the oxidation of reduced diphosphopyridine nucleotide by oxygen. In fact, it was shown that when β-hydroxybutyrate was substrate, all the phosphorylation occurred in the reaction between reduced diphosphopyridine nucleotide and oxygen, and none between substrate and diphosphopyridine nucleotide. With α-ketoglutarate[4], glyceraldehydephosphate[5] or pyruvate[6] (in certain micro-organisms only) as substrate, there is also phosphorylation linked with the initial dehydrogenation of the substrate. It is convenient to distinguish between oxidative phosphorylation of this type ('substrate-linked phosphorylation') and that associated with the further transfer of hydrogen atoms over the respiratory chain ('respiratory chain phosphorylation'). While considerable progress has been made in recent years with the elucidation of the mechanism of substrate-linked phosphorylation, little success has yet been met with in the case of respiratory chain phosphorylation. In fact, the particular hydrogen- or electron-transferring reactions in the respiratory chain which are associated with phosphorylation have not yet been identified. A detailed description of the mechanism of respiratory chain phosphorylation must await this identification. However, some recent findings have made it possible to suggest in general terms a mechanism in which the actual hydrogen-carriers are not specified.

Proposed Mechanism

The suggested mechanism is based on the following observations.

(a) In intact mitochondria, the passage of each pair of hydrogen atoms over the respiratory chain is coupled with the esterification of one, two or perhaps three atoms of inorganic phosphorus. The respiration appears to be compulsorily linked with phosphorylation[7], in the sense that inorganic phosphate and adenosine diphosphate are necessary for respiration.

(b) It is possible to obtain tissue preparations (for example, the Keilin and Hartree heart-muscle preparation[8]) which actively catalyse the aerobic oxidation of succinate or reduced diphosphopyridine nucleotide, without carrying out oxidative phosphorylation. Inorganic phosphate is not necessary for these reactions[8,9]. It has been suggested that these preparations consist of disrupted sarcosomal or mitochondrial membrane[10].

(c) A number of substances of widely different chemical structure can 'uncouple' phosphorylation from oxidation. In some cases (liver mitochondria[7], heart sarcosomes[11]), the rate of oxidation in the presence of inorganic phosphate, adenosine diphosphate, hexokinase and glucose is scarcely affected by the addition of a typical uncoupling agent, dinitrophenol; in the case of sarcosomes prepared from the flight muscles of the blowfly, the rate of oxidation is greatly increased[11]. The latter sarcosomes have an unusually low phosphorus to oxygen ratio.

(d) Some of the substances which 'uncouple' phosphorylation from respiration increase the rate of hydrolysis of adenosine triphosphate[12].

A common feature of the mechanisms of the substrate-linked phosphorylations (Racker[3]; Kaufman[4]) is that the dehydrogenated substrate is not immediately liberated, but remains bound to a grouping in the dehydrogenase molecule, from which it is freed by phosphorolysis reactions. In the present state of our knowledge, it seems worth while to see if the same general type of mechanism can explain respiratory chain phosphorylation. A mechanism along these lines is embodied in the following equations:

(1) $AH_2 + B + C \rightleftharpoons A{\sim}C + BH_2$

(2) $A{\sim}C + ADP + H_3PO_4 \rightleftharpoons A + C + ATP$

(3) $A{\sim}C + H_2O \rightarrow A + C$.

AH_2 and B are adjacent members of the respiratory chain and C is an additional component or grouping required for their interaction. A and C must be regenerated from the compound $A{\sim}C$ before hydrogen-transfer can proceed. In the intact mitochondria or sarcosome, this is brought about primarily by the transphosphorylating reaction (2), which leads to the esterification of inorganic phosphate. It is suggested that reaction (3) is relatively slow in the intact mitochondria, but can be greatly increased by dinitrophenol or other uncoupling agents. In this way, $A{\sim}C$ would be hydrolysed and be unavailable for the synthesis of adenosine triphosphate by reaction (2).

The idea that a compound like C mediates the conversion of the energy of an oxido-reduction into phosphate bond energy was first suggested in 1946 by Lipmann[13], whose mechanism may be described as:

$AH_2 + C \rightarrow A + CH_2$

$CH_2 + H_3PO_4 \rightarrow CH_2.H_2PO_3$ (CH_2 is first dehydrated)

$CH_2.H_2PO_3 + B \rightarrow C{\sim}H_2PO_3 + BH_2$

$C{\sim}H_2PO_3 + ADP \rightarrow C + ATP$.

An essential difference between the two mechanisms is that in Lipmann's scheme phosphate enters before, and in the scheme described in reactions (1)–(3) it enters after, the formation of an energy-rich bond. The latter scheme is suggested by the work carried out since 1946 in a field largely opened up by Lipmann's discovery of coenzyme A.

Since phosphorylation occurs more than once during the passage of hydrogen atoms through the respiratory chain, more than one set of reactions described by equations (1)–(3) will occur, in which AH_2 and B are different. It is possible, however, that a common mediator C occurs in all sets of reactions. This would not be the case with Lipmann's mechanism, since the $C \rightleftharpoons CH_2$ oxidation-reduction potential must be suitably related to those of the $A \rightleftharpoons AH_2$ and $B \rightleftharpoons BH_2$ systems[13].

Equations (1) and (2) are probably the sums of a number of partial reactions, which are not specified in full, because it is impossible to choose between alternatives. For example, the intermediate in reaction (2) could be A-phosphate, C-phosphate, A-adenosine diphosphate or C-adenosine diphosphate.

Effect of Dinitrophenol

The uncoupling action of dinitrophenol is explained if it promotes the hydrolytic reaction of $A{\sim}C$, thereby decreasing the amount of the latter available for the phosphorolytic reaction.

The different behaviour of liver mitochondria and heart sarcosomes, on one hand, and of blowfly sarcosomes, on the other (see paragraph (c) above), can be readily explained in the following way. The high phosphorus to oxygen ratio of heart-muscle sarcosomes and the relative insensitivity of the ratio to treatments which affect the rate of hydrogen-transfer[14] suggest that reaction (2) can proceed much faster than reaction (1); that is, the regeneration of A and C from $A \sim C$ is not a rate-limiting step. The addition of dinitrophenol, by promoting reaction (3), will stop the esterification of phosphate; but since it increases the rate of a process which is not rate-limiting, it will not increase the rate of hydrogen-transfer to any extent. The low phosphorus to oxygen ratio of blowfly sarcosomes, on the other hand, suggests that reaction (2) is relatively weak. The rate of hydrogen-transfer will, therefore, be increased by increasing the rate of breakdown of $A{\sim}C$, for example, by the addition of dinitrophenol. It is also understandable on this basis why lower concentrations of dinitrophenol are required to uncouple phosphorylation with the blowfly sarcosomes than with heart-muscle sarcosomes[11].

The different behaviour of heart and blowfly sarcosomes to the addition of dinitrophenol could also be explained by Lipmann's mechanism, if it is assumed that dinitrophenol increases the rate of hydrolysis of $C{\sim}H_2PO_3$. However, the mechanism described by reactions (1)–(3) is more successful in explaining the discovery of Loomis and Lipmann[15] that dinitrophenol abolishes the requirement of respiration for inorganic phosphate, since in the presence of dinitrophenol respiration proceeds by reactions (1) and (3), which do not involve phosphate.

The stimulation of reaction (3) by dinitrophenol not only explains the uncoupling of phosphorylation, but also the stimulation of the rate of hydrolysis of adenosine triphosphate, since the back-reaction of equation (2), followed by a rapid reaction (3), would cause the hydrolysis of adenosine triphosphate. This idea is essentially that of Hunter and of Lardy and Wellman[15], except that they suggest a phosphorylated compound (corresponding to $C{\sim}H_2PO_3$ in the above formulation of Lipmann's mechanism) as the intermediate the hydrolysis of which is stimulated by dinitrophenol (see also Green[16]).

In considering the possible mechanism of the stimulation of reaction (3) by inhibitors of oxidative phosphorylation, it is necessary to take account of the wide range of substances of varying chemical composition which can act as inhibitors. This strongly suggests that most of these substances, if not all, act by a relatively non-specific mechanism. It is likely that the enzyme catalysing reaction (3) is present even in the intact mitochondria in the absence of inhibitors, but it may be inaccessible to $A{\sim}C$, and the inhibitor acts by making the enzyme and its substrate accessible to one another. An explanation of this type is supported by the fact that incubation of mitochondria or sarcosomes, which causes well-defined changes in the morphology of the granules, brings about a loss of respiratory chain phosphorylation; for example, that associated with the oxidation of succinate or β-hydroxybutyrate. This explanation would not exclude the possibility that some inhibitors of oxidative phosphorylation might react by a more specific mechanism, for example, by actual participation in reaction (3) (see Lardy and Wellman[15]).

Respiratory Chain Activity in the Absence of Inorganic Phosphate

The oxidation of succinate or of reduced diphosphopyridine nucleotide by the Keilin and Hartree heart-muscle preparation in the absence of inorganic phosphate can be explained in two ways: (i) during the preparation of these particles from the sarcosomes, the mutual accessibilities of the components of the respiratory chain are altered in such a way that reactions (1), (2) and (3) are replaced by the simple hydrogen-transferring reaction:

$$(4)\quad AH_2 + B \rightarrow A + BH_2\,;$$

or (ii) even in this preparation, C is necessary for the reaction between AH_2 and B, and the preparation also contains the enzyme catalysing reaction (3). This would mean that this hydrolytic enzyme is, like all the components of the respiratory chain, firmly bound to the insoluble portion of the sarcosome, which resists the disintegration treatment. However, the enzyme catalysing reaction (2) may be lost during the preparation.

While the first explanation is adequate for studies with the Keilin and Hartree heart-muscle preparation of hydrogen-transfer without accompanying phosphorylation, the second has the advantage that it eliminates the necessity of postulating that C is essential for the reaction between AH_2 and B in the intact sarcosome, but is not required in the disintegrated sarcosome, which still contains all the components of the respiratory chain firmly bound to the particles. It is simpler to assume that the reactions which are retained in the disintegrated sarcosomes follow the same course as in the intact sarcosomes.

In any event, reaction (4) does not take account of an important difficulty in any formulation of the mechanism of the respiratory chain. Although kinetic studies[17] suggest that the components react together by binary collision, the independence of the rate of reaction on the degree of dilution shows that the components are very firmly bound to the particles. This suggests that the mechanism may, in fact, be much more complicated than indicated by reaction (4).

Utilization of Respiratory Energy

An essential feature of the proposed mechanism is that the free-energy change in the reaction $AH_2 + B \rightarrow A + BH_2$ is not immediately liberated as heat, but remains chemically available in the compound $A{\sim}C$. Thus an essentially irreversible oxido-reduction reaction could become easily reversible. The energy in $A{\sim}C$ may either be utilized in reaction (2) to synthesize adenosine triphosphate, another reversible reaction, or be lost as heat in the irreversible hydrolytic reaction (3). But it would be unwise to assume that adenosine triphosphate is the only energy-rich compound which the cell can utilize. It is possible that $A{\sim}C$ might itself be used in some reactions. Woolley[18] has recently directed attention to the possibility of the utilization in the cell of energy-rich bonds, other than the pyrophosphate bond. If the $A{\sim}C$ bond can be used in this way, it is important to note that it can be formed in two ways, either by the respiratory chain reaction (1) without the intervention of phosphorus, or from adenosine triphosphate by reversal of reaction (2). This is exactly analogous to the case of acetyl–coenzyme A, the general acetylating agent in the cell. Acetyl–coenzyme A may be formed either by the oxidative decarboxylation of pyruvate in the complete absence of phosphorus[19], or by the reaction of coenzyme A, acetate and adenosine triphosphate[20].

If $A{\sim}C$ is concerned in certain energy-requiring processes in the cell, the reverse of reaction (2) might be a way in which adenosine triphosphate produced by fermentation or glycolysis could be utilized under anaerobic conditions by cells possessing the necessary enzymes. These processes would be expected to be prevented by any substance, for example, dinitrophenol, causing the breakdown of $A{\sim}C$. Thus, dinitrophenol would prevent the utilization, not the synthesis, of adenosine triphosphate. This would also be the case if the adenosine triphosphate formed anaerobically were utilized by another mechanism, since dinitrophenol causes its hydrolysis. Either of these possibilities might be the explanation of one puzzling action of dinitrophenol. It has been shown with extracts that the reactions in glycolysis or fermentation which bring about the formation of adenosine triphosphate are not susceptible to dinitrophenol[21]. Nevertheless, energy-requiring processes such as enzyme adaptation in yeast[22], or uptake of glutamate by *Staphylococcus aureus*[23], are inhibited by dinitrophenol, even under anaerobic conditions. On the other hand, the transport of ions by erythrocytes, a process also receiving its energy from glycolysis, is not affected by dinitrophenol[24]. This is understandable on the basis of the above explanation, since erythrocytes do not contain a complete respiratory chain, that is, they may not contain A.

The suggestion that $A \sim C$ might itself be used directly for certain energy-requiring processes raises the possibility that the energy of certain steps of the respiratory chain is normally utilized in this way and not via phosphorylation. The measurement of the yield of phosphorylation in respiration might not be a complete measure of the efficiency of utilization of the energy potentially available from respiration.

Conclusion

In conclusion, it should be emphasized that many of the features of the proposed mechanism are based on analogy with reaction schemes describing the participation of coenzyme A or the sulphydryl group of glyceraldehydephosphate dehydrogenase in substrate-linked phosphorylation which have recently been worked out by Racker[4] and Kaufman[4]. While there is no reason why similar reactions should necessarily operate in respiratory chain phosphorylation, the fact that the suggested mechanism offers possible explanations of some puzzling findings is some justification for believing that this might be the case. However, much more experimental evidence is required. It is obvious without considering any particular mechanism that the identification of AH_2 and B from among the comparatively few and well-studied components of the respiratory chain remains an urgent task. But it could be important to recognize that a third substance might be required for their interaction. A fat-soluble substance is a possibility to be kept in mind, since about 40 per cent of the dry weight of the Keilin and Hartree preparation is phospholipid.

I wish to thank Prof. D. Keilin for his interest and advice. This work was carried out on behalf of the Agricultural Research Council. [Aug. 21.

AUSTRALIAN COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

ANNUAL REPORT FOR 1951–52

IN the annual report of the Commonwealth of Australia Scientific and Industrial Research Organization, covering the year ended June 30, 1952*, material is arranged according to its subject rather than the Division or Section concerned. Expenditure during the year totalled £3,880,098, including £886,735 from sources other than the Commonwealth Treasury, notably £292,046 from the Wool Industry Fund and £420,423 from the Wool Research Trust Fund. Some progress is reported in the erection of new buildings, and the new laboratory for the Division of Tribophysics was expected to be ready for occupation early in 1953; several of the main buildings of the Sheep Biology Laboratory at Prospect, New South Wales, were almost ready for occupation, and reasonable progress has been made with buildings for the Wool Textile Research Laboratory at Geelong. A new series of publications dealing in non-technical language with various aspects of the Organization's sheep and wool research programme was initiated during the year and a new periodical, *Rural Research in C.S.I.O.R.*, was established to provide a summary of recent agricultural research and to stress its practical significance. Stress is also laid on the extent of collaboration with universities, and a large number of research workers are now engaged either in units established by the Organization in university buildings or in its own buildings on university property, in sections established to work in existing university laboratories with the professor as officer-in-charge, or on specific research projects for which the universities accept complete responsibility supported by funds supplied by the Organization.

Detailed surveys carried out by the Division of Soils covered 103,000 acres, and broad-scale surveys covered about 13,100 square miles in all States and in the Northern Territory, while a new soils map for Australia is being compiled and a manual of Australian soils is in the press. In soil chemistry a suitable potentiometer and amplifier were being assembled for assessing the hydrogen-ion status in suspensions of cation-dominant soils, while a simplified technique has been successfully applied to the determination of total exchange capacity in small samples of soils. Progress is reported in the chemical study of the inter-relationships of terra rossa and rendzina soils, and the study of soil chemistry of micro-nutrient metals was continued. A study was being made of the availability to the fungus *Aspergillus niger* of the metals iron, zinc, copper, manganese and molybdenum from finely ground rocks and unweathered materials such as are often found in the parent material of Australian soils, and the respiration of micro-organisms in deficient soils was being compared before and after the addition of trace elements, with the view of determining whether micro-organisms compete seriously with higher plants for such trace elements in deficient soils. A laboratory study of the effect of the impacting of surface layers of soil by heavy rain was in progress, as well as a study of the effect of a temperature gradient on the rate of diffusion of water vapour in soils. A method has been established for determining field capacity by draining soil aggregates at a definite water tension.

---

* Fourth Annual Report of the Commonwealth Scientific and Industrial Research Organization for the Year ending 30th June, 1952. Pp. 173. (Canberra: Govt. Printer, 1953.) 10s.

During the year the international exchange of plants and seeds greatly increased, largely as a result of overseas plant exploration, more than three thousand samples being received from overseas and about seventeen hundred sent in exchange to forty-eight countries. Plant exploration in the Mediterranean region was continued, and a major collecting effort was made in Africa in search of suitable grasses and legumes for Queensland. A strain of *Sorghum* introduced from Brazil has shown promise as a fodder plant, and a study of the reactions of the resistant hybrids of the potato to the different viruses has indicated that resistance is due to the presence of virus-inactivating systems and not to hyposensitivity. Further studies of the persistence of both virus *X* and tobacco mosaic virus in tomato roots have been initiated to ascertain whether these viruses can continue to multiply in roots kept in darkness or are dependent on exposure to light. The results of a survey of a range of varieties of apples at two crop levels indicate that the keeping capacity of large-size fruit is most likely to be improved when manurial and cultural treatments designed to increase the size of the fruit increase the cell number per fruit without increasing the cell size. Soil sterilization experiments on soil infested with nematodes showed that satisfactory growth of apple seedlings could be obtained after treatment with D-D and formalin. The study of *Duboisia* spp. as sources of hyoscine and atropine, and of varieties of opium poppy as sources of opium alkaloids was being concluded. Samples of thirty-two substances obtained during the phytochemical survey of the flora of Papua and New Guinea were sent to the Sloan-Kettering Institute for Cancer Research for tests of anti-tumour activity.

At Canberra laboratory investigations on tobacco were continued, and at Ayr field investigations in association with the Queensland Department of Agriculture, while trials have been maintained with potassium, copper, zinc, molybdenum, manganese, iron, magnesium and boron on soils on the Southern Tablelands of New South Wales. Chemical examination has confirmed the identification of the degree of trashiness in uncured tobacco leaf determined by means of fluorescence; the trashy leaf does not fluoresce under ultra-violet light. In plant physiology work has continued on correlating the mechanism associated with, and controlling, plant development. Surveys of the distribution of skeleton weed (*Chondrilla juncea*) in relation to soil, climatic and land-use factors have been commenced. Rhizomatous grasses, such as Johnson grass and couch grass, have been successfully controlled with trichloroacetates at Canberra and Griffith, and screening tests on new herbicides were in progress at Griffith. With the object of obtaining a suitable grazing legume for wheat and sheep areas where conditions are unfavourable for subterranean clover, many annual medicks have been submitted to field trials, the most satisfactory results being obtained with a barrel medick (*Medicago tribuloides*) from Forbes, New South Wales, a burr medick (*M. hispida reticulata*) from Turkestan, and a short-spined variety (*M. hispida terebellum*) from Malta. A theoretical study of the movement of water into homogeneous unsaturated soils has been completed, and about 3,500 square miles of the 16,000 square miles to be covered in the ecological survey of the New England region have been mapped. An experiment conducted at Perth involved a comparison of continuous and autumn-deferred grazing on a sown annual pasture with merino wethers, and the results of a long-term grazing management trial of the effect of light, medium and heavy rates of stocking Mitchell grass pasture at Cunnamulla, Queensland, were being prepared for publication. At the Kimberley Research Station the immediate objectives were to determine whether the Black Soil Plains of the Ord river are satisfactory for grazing and whether a stable system of agriculture can be devised.

Irrigation research is carried out principally at the Commonwealth Research Station, Merbein, Victoria, which is concerned chiefly with irrigation problems in the middle and lower Murray River valley, special attention being given to the growth-cycle of the sultana vine, and at the Irrigation Research Station, Griffith, New South Wales, where besides drainage and related soil problems in semi-arid and arid regions, soil fertility problems and horticultural problems, including factorial field experiments with citrus, are receiving attention. At the McMaster Animal Health Laboratory, Sydney, further trials with phenothiazine against *Haemonchus contortus* have confirmed that large particles greatly detract from the efficiency of the drug. Some seventy-two compounds were tested against *H. contortus* by injection into the rumen, and studies on the biological activity of complex ions prepared in the Chemistry Department of the University of Sydney indicated that their biological activity results from the poisoning of certain enzymes. At the Veterinary Parasitology Laboratory at Yeerongpilly, Queensland, studies of 'Queensland itch', an allergic reaction of the horse to the bites of a sandfly, a new species of *Culicoides*, were almost completed. At the Fleece Analysis Laboratory, Villawood, New South Wales, where 23,412 measurements were made during the year for the Division of Animal Health and Production, including yield determination, density, mean diameter, staple length and crimp, an economy of 50 per cent was effected in the use of detergents and in electric power for the large scour. The general research programme at the Poultry Research Centre, Werribee, Victoria, remained unaltered. The studies on cobalt deficiency in sheep, with the publication of maps showing the widespread distribution of cobalt deficiency in southern Australia, have led to the use of cobalt-containing licks as supplements for flocks, with a dramatic improvement in their general health and productivity. Experiments have been made to determine the relative efficacy of widely spaced dosing with quantities of cobalt greater than would be required for frequent administration, while the methods evolved for fighting the maladies arising from copper deficiency in sheep are now universally employed in the affected areas. Other studies relate to the effect of molybdenum on the copper metabolism of sheep, the nutritional physiology of cobalt-containing vitamin B_{12}, the processes of rumination, carbohydrate metabolism, chronic fluorosis, infertility and physiology of reproduction and energy metabolism. A series of complete energy-balances on sheep confined to rations of dried lucerne have established the fundamental law that the extra heat production which occurs on feeding is linearly related to the amount of combustible energy in the digestion products that are absorbed. Studies were continued on chronic copper-poisoning of sheep, on the resistance of sheep to nematode parasites, and on protection against body blowfly strike, while work on cattle has included attempts to improve the toxicity of DDT to cattle tick, and studies on the loss of efficiency of benzene hexachloride dipping fluids, on the distribution of tick larvæ in a paddock and on the physiology of milk secretion.

The main emphasis in the work of the Division of Entomology is on the elucidation of fundamental facts about insects with the idea of finding weaknesses in the insect's defence where it can be most effectively attacked. Further progress has been made in elucidating the mechanisms involved in keratin digestion, and it has been established that keratin-digesting insects are characterized by the high reducing capacity of their mid-gut juices. Experiments with the sheep blowfly have shown that heavy destruction in certain circumstances leads to much higher population levels, although in other circumstances the population is reduced, and the definition of the conditions under which these effects are produced appears to be leading to conclusions of great practical importance. Relatively small field experiments indicate that the Argentine ant can be eradicated from residential areas by applying barrier sprays containing two per cent chlordane in the form of a grid over the area: treatment inside houses is unnecessary for complete control. A survey has been commenced of the distribution, seasonal incidence and relative economic importance of caterpillar pests of pastures and field crops in Australia. Investigations were continued on three strains of houseflies differing in susceptibility to DDT.

Fisheries research has included ecological investigations on an enclosed brackish-to-fresh lake on Moreton Island, Queensland, and on a partly enclosed area in Port Hacking, a full programme of investigations on the humpback whale, investigations on the racial relationships of salmon from Western and South Australia and Tasmania, on the alleged deterioration of trout fishing in Tasmania, on fresh-water fish culture in Tasmania, on the microbiology of the inter-tidal estuary in relation to fish and oyster culture, and on pearl shell and oyster hydrology. A paper on the biology of the school shark was almost complete, and the plankton programme was redesigned to provide data to study the regional and temporal fluctuations of the composition, succession and relative abundance of the plankton.

Some of the work of the Division of Food Preservation and Transport was also concerned with chemical methods for estimating the spoilage of fish. A second paper has been published on the fundamental principles of canning processes, and an experimental survey of fruit cool stores in the deciduous fruit-growing areas of New South Wales, Victoria and Tasmania has been completed. An accurate and rapid method for determining nitrogen in the most refractory heterocyclic amino-acids has been devised, while polarographic methods have been used extensively in the investigation of the combination of amino-acids with heavy metals and in determining trace elements in canned foods. Microbiological investigations were concerned mainly with those environmental factors which affect the growth or death of food-spoilage micro-organisms, while the work of the new Plant Physiological Research Unit has helped to provide a background of the knowledge of the behaviour of cells and tissues required for the proper understanding of fruit and vegetable storage problems. During the past three years investigations have been directed towards finding the rate at which a pea crop matures, and there are preliminary indications that it will be possible to predict the weight of cut vines to be transported to the vining station and the yield of peas to be handled in the cannery. The maturometer, an instrument developed for the rapid measurement of maturity, has been patented and is now being produced commercially under licence. The use of fatty-acid esters, containing a paraffin chain of suitable length with a polar group at one end, in the cold-dip process for sultana drying has been further investigated, and further work has been done on the utilization of skim-milk solids by addition to bread, as well as on cheese starters and the flavour chemistry of Australian cheddar cheese.

The Division of Forest Products has identified more than eleven hundred timber specimens during the year, and has revised completely the card-sorting key developed to place timbers in their correct families or family groups. A preliminary study has been made on the removal of lignin and pentosan from *E. regnans* on alkaline pulping, and on the effect of temperature, time and concentration on the yield and permanganate number of the pulp. Two cationic urea formaldehyde resins gave satisfactory wet-strength development when applied to bleached and unbleached eucalypt kraft pulps. A detailed study has been made of the variation in shrinkage throughout a tree of *Eucalyptus regnans*, and much work has been done on the mechanical properties of radiata pine grown in Victoria. Tests with the high-pressure pilot cylinder have indicated that preservative treatment of the heartwood of eucalypt timbers is possible. Preliminary work to develop a standard laboratory technique for determining the resistance to decay of timbers has been almost completed as well as a study of the drying behaviour of twenty New South Wales and Queensland rain-forest species. Observations were made on the effectiveness of incorporating benzene hexachloride in casein glue for immunizing plywood against *Lyctus* borer damage, and interest was maintained in the utilization of waste wood.

In the Division of Building Research, where some cuts had to be made in the research programme, concrete investigations centred on foamed concrete made by the entraining process, while the study of the relation between the flow properties and the composition of oil-based caulking compounds continued with direct measurements of the flow properties of thick pastes. A study of concrete floor surfaces to determine the conditions necessary for concrete floors to be acceptable in domestic construction is almost complete, and a new mathematical treatment has made practicable the calculation of temperatures inside houses and other buildings exposed to fluctuating external temperatures. Polystyrene tiles installed three and a half years ago in kitchens and bathrooms are still giving good service, but bond failures are now extensive on all types of background where the filled drying oil–resin type of adhesive has been used.

A major objective of the work on wool textiles is to improve the competitive position of wool relative to synthetic fibres. Investigations in progress included the relationship of elastic properties to processing behaviour and 'handle'; the interaction between wool and water and its effect on mechanical behaviour; and elastic behaviour under loads insufficient to remove crimp. The molecular structure of proteins was being investigated by studies of the constituent α-amino-acids and lower peptides by

X-ray crystallographic and infra-red spectroscopic methods, while an examination of cultures of *Aspergillus oryzae* by paper chromatography and filter-paper electrophoresis has revealed many enzymes capable of attacking the products of cellulose degradation. Of moulds capable of initiating the breakdown of cellulose, *Stachybotrys atra* has been selected for intensive study. A detailed survey has been made of the scutching operation and the staff problems it involves in Victoria flax mills; considerable progress is reported in developing economical methods of utilizing short flax crops, and work has been continued on the identification and estimation of materials associated with the cellulose of flax fibre and their effects on the spinning quality of the fibre.

Besides its work on processing the titaniferous uranium ores of South Australia, the Division of Industrial Chemistry has been concerned with the utilization of the extensive deposits of high-grade rutile from eastern Australian beaches, the separation of thorium, cerium and the cerium group of lanthanons, the fundamental and applied aspects of dry-cell chemistry, the general mechanism of the cement-aggregate reaction, and the physical properties of fluids as affected by temperature and pressure; and applications have been filed for patents covering a process of separating antibiotics such as penicillin and streptomycin by counter-current extraction in which a solid absorbent of the antibiotic descends through a rising column of liquid which removes the contaminants. The *p*H gradient in the adsorption columns corresponds to the temperature gradient of a distillation column. A highly successful column partition chromatographic method has been developed for determining variations in the alkaloid content of the hepatotoxic *Heliotropium europaeum*, and a study of the rate of reaction of phenols and formaldehyde was continued. Tannin–formaldehyde adhesives for plywood which maintain their fluidity long enough for commercial requirements have now been obtained by first heating the tannin solution with sodium sulphite, while yields of more than 60 per cent of a-tetramethyl dihydropyridine have been obtained from acetone and ammonia using an alkali catalyst.

The study of the flotation process has been continued, and satisfactory progress has been made in a comprehensive survey of the ignition and combustion characteristics of Australian coals with particular reference to the evaluation of coal for combustion. In the Division of Tribophysics advances are reported in our understanding of the distortions produced by plastic deformation, of phase changes in metals and of the mechanism of the slow combustion of hydrocarbons. Work is being done on diffusion on solid surfaces, and on the properties of surface films of long-chain compounds and of silicone lubricants. As during 1950–51, the work of the Division of Metrology has been directed largely towards meeting statutory requirements in respect of national standards. Some experience has been gained with the use of the geodetic base, and satisfactory progress made in the production of the working standards of mass. Development work has been continued on instruments and techniques for the precise measurement of engineering quantities such as force, pressure, stress and strain, angular speed, hardness and vibration, while the Division of Physics is likewise engaged in research designed to increase the precision of maintenance of standards and the measurement of basic physical quantities, particularly in temperature and photometry. Theoretical studies have also been made of electrical and thermal conductivity at low temperatures, and the efficiency of the helium liquefier has been improved. The Division of Electrotechnology, which forms part of the National Standards Laboratory, has also been investigating the dielectric properties of mixtures and of hydroxy compounds as well as the marked increase in conductivity of inorganic salts, minerals and some inorganic compounds when they are freshly ground.

Following the discovery in the United States of an atomic spectral line in the radiation from the galaxy, the Division of Radiophysics completed the first survey of these radio waves over the sky. A radio interferometer of thirty-two aerials was brought into operation and was being used for detailed observations of the sun, while, besides an extensive study of the effects of magnetic storms on the ionosphere, substantial progress has been made in work on the physics of rain and clouds and on the artificial production of rain. Statistical arguments in the Radiophysics Laboratory have established the existence of two classes of radio stars, and it has also been established that radio stars have angular diameters up to a degree. The development of the Division's microwave navigation system was virtually completed. Experiments on the measurement of the momentum and ionization of charged cosmic-ray particles were continued; the work on tracer elements has been reorganized and is now being carried out in a section of the Organization located in the Chemistry School of the University of Melbourne. In nuclear physics the main activities have been centred around the three particle accelerators and the cosmic-ray spectrometer. The 750-kV. high-current electrostatic generator was being operated continuously, and the 14-MeV. electron synchrotron became fully operational. The work on analogue instruments has been devoted mainly to operational use of the Organization's differential analyser, while work on electronic devices for use with digital machines has been concentrated on the development of the beam-deflexion type of high-vacuum tubes for carrying out logical binary functions.

PILTDOWN MAN

A CRITICAL re-examination of all the Piltdown specimens was undertaken this year by the British Museum (Natural History) in conjunction with the Department of Anatomy, University of Oxford. The results, published over the names of Dr. J. S. Weiner, Dr. K. P. Oakley and Prof. W. E. Le Gros Clark, demonstrate clearly that the jaw and the canine tooth are in fact deliberate frauds (*Bull. Brit. Mus.* (*Nat. Hist.*), 2, No. 3; 1953). The Piltdown brain-case must still be regarded as a genuine fossil (an Upper Pleistocene variety of modern man). The jawbone and tooth which had been falsely associated with this human cranium were so entirely out of character that, even when allowance was made for different parts of the human skull having evolved at different rates, it became increasingly difficult as time went on to reconcile them with the evidence of human evolution obtained elsewhere. The removal of the 'ape-jawed Piltdown man (*Eoanthropus*)' from the fossil record thus actually clarifies the problem of human ancestry.

In their remarkably flat wear the molar teeth in the Piltdown jawbone resemble man rather than ape.

Microscopical examination of these flatly worn surfaces showed that they are due to artificial abrasion and not to natural wear. The canine is a young tooth with incomplete root, so the fact that it has been worn right down to the pulp cavity, as in an aged individual, is only explicable by artificial abrasion.

Re-determination of the fluorine content of all the specimens, using an improved technique, has shown that whereas the brain-case contains the same amount of fluorine as some local Upper Pleistocene fossils, the jawbone and the canine contain no more than modern specimens. The organic content of all the specimens has also been determined. The jawbone and the canine contain as much nitrogen as fresh bones and teeth; but the brain-case contains only the small quantity expected in Upper Pleistocene fossils.

Finally, evidence has been found which indicates that the jawbone was artificially stained by iron salts and potassium dichromate prior to its being 'discovered' by the excavators. Some who were at first sceptical about the association of the human brain-case with an ape-like jaw and canine tooth became convinced that it was a genuine association, and not a fortuitous one, when it was announced that remains of another individual had been found at a second site. Tests applied to the two pieces of skull bone alleged to be from the second site show that whereas one piece is fossilized and probably belongs to the skull from the first site, the other piece is comparatively modern and has been artificially stained in an attempt to match it in colour. A molar tooth reputed to be from this second site shows signs of artificial abrasion and almost certainly came from the original 'Piltdown mandible'.

The tests and other investigations reported above were carried out jointly in the Departments of Geology and Mineralogy of the British Museum, in the Department of Anatomy and the Clarendon Laboratory, University of Oxford, and in the Department of the Government Chemist, London.

These investigations serve to confirm the doubts expressed by certain men of science during the controversy which raged for some years after the original discovery in 1912. For example, exactly forty years ago, Prof. D. Waterston, then professor of anatomy in King's College, London, after superimposing tracings of the radiograms of the Piltdown mandible and that of a chimpanzee, wrote (*Nature*, 92, 319; 1913): "The similarity of the specimens brought out in this way is very striking, for the outlines are practically identical. . . . The cranial fragments of the Piltdown skull, on the other hand, are in practically all their details essentially human. If that be so it seems to me to be as inconsequent to refer the mandible and the cranium to the same individual as it would be to articulate a chimpanzee foot with the bones of an essentially human thigh and leg". A similar view was expressed by Mr. G. Miller, jun., in the United States after systematic comparison of the casts of the Piltdown fossils with the corresponding bones of men and apes.

OBITUARY

Dr. O. F. Hudson

Dr. Hudson, whose death occurred on October 8, had taken an early and prominent part in the development and application of the techniques of metallography and thermal analysis, and had made valuable contributions to progress, both as a teacher and by his researches, at a time when there were but few workers in this field.

Born in 1878, Oswald Freeman Hudson was educated at Alleyn's School, Dulwich, and entered the Royal College of Science in 1897, taking the associateship in chemistry in 1900. After a period at the Royal School of Mines, under Prof. Roberts-Austen, he went to the Mint as one of his research assistants. It was there that he had what was at that time the almost unique opportunity of acquiring experience in metallurgical research, under the guidance of the late Prof. W. H. Merrett. Work was then in progress for the sixth of the series of reports which Roberts-Austen had made to the Alloys Research Committee of the Institution of Mechanical Engineers during the preceding decade.

In 1902 the late Prof. Thomas Turner was engaged in planning and equipping the Metallurgical Department in the new buildings of the University of Birmingham, and Hudson went there as his lecturer in metallurgy. During the next fourteen years he devoted himself wholeheartedly both to teaching and to research. His work, chiefly on the copper-zinc alloys, and partly in collaboration with the late Dr. G. D. Bengough, appeared in the *Journal of the Society of Chemical Industry*. With the advent, in 1908, of the Institute of Metals, of which he was an original member, he became a regular contributor to the *Proceedings* and discussions of that body. He took a leading part in forming the London Local Section, and became the first chairman in 1921. The breadth of his metallurgical interests while at Birmingham is shown by the publication of a concise but admirable text-book on "Iron and Steel" in 1913, to which his friend Bengough contributed a section on corrosion.

In 1916, Hudson returned to London to collaborate with Bengough in the urgent work of the Corrosion Research Committee, sponsored by the Institute of Metals and under the chairmanship of the late Sir Harold Carpenter at the Royal School of Mines.

Two years later he was appointed metallurgist to the Admiralty Engineering Laboratory at West Drayton, Middlesex. There he remained until 1924, the nature of his work being confidential. Returning to Birmingham, he then assisted Dr. R. S. Hutton (now emeritus professor at Cambridge) in setting up the British Non-Ferrous Metals Research Association, afterwards transferred to the present buildings in Euston Street, London. As research superintendent he served this body for the next fifteen years, and was retained as consultant until 1944. During the Second World War he resumed his association with Prof. Hutton as a part-time lecturer at Cambridge and he also responded to a similar call for assistance at the Royal School of Mines.

Thus, over a period of more than forty years, Dr. Hudson had taken a prominent part in many new metallurgical developments and had witnessed the striking advances that have been made. His self-effacing modesty and natural gift for friendly collaboration had endeared him to a wide circle of fellow-metallurgists, who, either as former students or as colleagues, had profited by his guidance and help in their work.

S. W. Smith

NEWS and VIEWS

Mineragraphic Section of the Australian Commonwealth Scientific and Industrial Research Organization : Dr. F. L. Stillwell

Dr. Frank L. Stillwell has recently retired from his post as officer-in-charge of the Mineragraphic Section of the Australian Commonwealth Scientific and Industrial Research Organization after a long and successful career as a geologist and mineralogist mainly in the service of various government organizations in Australia. As a young graduate of the University of Melbourne, Dr. Stillwell was selected as a member of staff of the Australian Antarctic Expedition of 1911–14, and his studies of the metamorphic rocks encountered during that assignment attracted world-wide interest. Then for a time he was engaged on gold research and made notable contributions to geological thought concerning the origin of the Bendigo auriferous quartz reefs. In association with the Mines Department of New South Wales he contributed notably to knowledge of the Broken Hill Lode and the rocks of its immediate environment. Dr. Stillwell spent the years 1922–23 visiting South Africa, Europe and the United States. On return to Australia the application of newly acquired techniques in the investigation of opaque ore-minerals led him to reveal important economic considerations in the mechanical treatment of Broken Hill ores preparatory to smelting. He was then, in 1927, appointed petrologist to the Mineragraphic Research Section of the Council for Scientific and Industrial Research, now the Commonwealth Scientific and Industrial Research Organization. Since then his Research Section has developed, with marked efficiency, to great importance in the field of economic geology in Australia. His personal contributions have been many and his achievements widely recognized, culminating in the award by the Australian Institute of Mining and Metallurgy of its much-prized medal.

Dr. A. B. Edwards

Dr. A. B. Edwards, who succeeds Dr. Stillwell, graduated in the Department of Geology of the University of Melbourne and was awarded an 1851 Exhibition scholarship to continue his studies at the Imperial College of Science and Technology, London. His first major undertaking was an extensive petrological investigation relating to Victorian Cainozoic basalts, and this was followed by a notable contribution to the petrology of the Tertiary basalts of the Kerguelen Islands, dealing with material collected by the British, Australian and New Zealand Antarctic Research Expedition. On his return to Australia, Dr. Edwards was appointed to the Mineragraphic Laboratory as assistant to Dr. Stillwell, and there he has proved a most assiduous and able investigator in a wide range of problems undertaken in that Laboratory, contributing notably to mineralogical and petrological science in Australia. Among his major works in this connexion are field and laboratory studies of the great iron-ore deposits at Yampi Sound in north-western Australia and of the better-known iron-ore deposits of the Middleback Ranges in South Australia. Dr. Edwards now occupies a unique position among Australian petrologists and mineralogists.

Agricultural Research Council : Appointments

The Agricultural Research Council announces that Dr. R. Scarisbrick has been appointed to an additional post of scientific assistant to the Secretary of the Council. Dr. Scarisbrick, who will act as the Secretary's assistant in the fields of animal health and husbandry, will have the rank of deputy chief scientific officer. He will take up his new duties on January 1, 1954. Dr. Scarisbrick graduated in biochemistry and after a period of research work in Cambridge and at the Maudsley Hospital took his veterinary qualification at the University of Liverpool. His research experience includes work on the physiology of ruminants under the late Sir Joseph Barcroft and studies in pathological physiology in the former Institute of Animal Pathology, Cambridge. Since 1949 Dr. Scarisbrick has held the appointment of lecturer in animal pathology in the University of Cambridge School of Veterinary Medicine.

The Council also announces that Dr. E. E. Cheesman has been promoted to the grade of deputy chief scientific officer with effect from July 1. Prior to his joining the staff of the Council in 1949, as one of the scientific assistants to the Secretary, Dr. Cheesman was professor of botany in the Imperial College of Tropical Agriculture, Trinidad. He is responsible for advising the Secretary on matters affecting research on plants and soils. The mycological and entomological aspects of this work will continue to be the special responsibility of Mr. G. G. Samuel, also a scientific assistant to the Secretary and formerly chief plant pathologist at the Harpenden Laboratory of the Ministry of Agriculture.

University of Leeds

Dr. S. Mackey is on leave for a year from his lectureship in the Department of Civil Engineering, University of Leeds, to go as professor of civil engineering at the Indian Institute of Technology at Kharagpur. The University has received the following gifts : renewal of £750 a year for a further two years to the Department of Pharmacology from the Wellcome Research Laboratories and £315 to the Department from Boots Pure Drug Co., Ltd., Nottingham ; renewal of £600 a year for a further seven years from Turner and Newall, Ltd., Manchester, for Fellowships in engineering, inorganic chemistry or physics.

Atomic Energy Development

In reply to questions in the House of Commons, on November 9, Mr. Duncan Sandys, and on November 10, the Prime Minister, affirmed the Government's readiness to welcome collaboration in the field of atomic energy on a reciprocal basis with the Government of the United States ; but Mr. Sandys pointed out that the Atomic Energy Commission of the United States continues to be precluded by legislation from any effective exchange of information on these matters. In reply to further questions on November 10, the Prime Minister said that he would have the possibility of treating the development of atomic energy for industrial purposes as a Commonwealth matter rather than primarily as a domestic matter studied by the Departments concerned.

Replying to questions regarding uranium deposits, Mr. Sandys said that the most promising region in Great Britain for uranium discoveries is in Cornwall. Pockets of uranium ore occur there; but the quantities so far found would not justify the expense of mining and treatment. The Government's decision to rely on uranium deposits overseas is therefore not a question of policy, but of necessity.

Expenditure of the Department of Scientific and Industrial Research

In a written answer to a question regarding the expenditure of the Department of Scientific and Industrial Research, on November 12, Mr. J. A. Boyd-Carpenter, Financial Secretary to the Treasury, agreed that there had been some slight fall in real expenditure of the Department in 1952–53 compared with 1951–52 and 1950–51. The 1953–54 estimates for the Department, however, provided for an increase of about £400,000 over the 1952–53 level, and a general understanding had been reached between the Department and the Treasury which provided for the gradual expansion of the Department's activities over the next five years.

Analytical Abstracts

The Society of Public Analysts and Other Analytical Chemists has provided abstracts of the literature on analytical chemistry for readers of *The Analyst* ever since the journal was first published in 1876. For the past four years these abstracts have been prepared by the Bureau of Abstracts and supplied to members of the Society and to subscribers to *The Analyst* under the title *British Abstracts C*. The Bureau will cease to exist at the end of this year, and *British Abstracts* will no longer appear in its present form. The Society has therefore decided to issue a new publication, to be called *Analytical Abstracts*, which will cover the whole range of analytical literature in the same way as did *British Abstracts C*. *Analytical Abstracts* will be edited by Dr. Norman Evers and published for the Society by W. Heffer and Sons, Ltd., of Cambridge. It will be published each month in a format similar to that of the abstracts included in *The Analyst* prior to 1950 and will be available in the new year to members of the Society and to subscribers on the usual terms; it will also be sold separately at 50*s*. a year, including the index, or at 60*s*. a year, printed on one side only, without the index.

Journal of Protozoology

The Society of Protozoologists is to publish a new *Journal of Protozoology*, beginning in the spring of 1954. Papers concerned with original work on any aspect of the study of Protozoa may now be submitted to the editor, William Trager, Rockefeller Institute for Medical Research, 66th St. and York Ave., New York 21, N.Y. The journal will consist of four issues a year. The annual subscription will be 9 dollars for all except graduate students, for whom it will be 6 dollars. Inquiries regarding subscriptions and membership of the Society of Protozoologists should be addressed to Norman D. Levine, Secretary, College of Veterinary Medicine, University of Illinois, Urbana, Illinois.

Ammonia Assimilation by *Chlorella*

P. J. Syrett (*Ann. Bot.*, N.S., 17, 65, 1; 1953), in a study of the assimilation of ammonia by nitrogen-starved cells of *Chlorella vulgaris*, has observed that the addition of ammonium sulphate to the culture solution is followed immediately by the rapid assimilation of ammonia and a notable increase in the respiration-rate. This continues until all the ammonia has been assimilated or until some carbon reserve within the cells has been used up. The ammonia is converted into soluble organic nitrogenous compounds, free or combined α-amino-nitrogen or amide-nitrogen during the initial phase of the experiment. Later a smaller proportion of the assimilated ammonia is found in these fractions while appreciable quantities of basic amino-acids are formed. With this assimilation there is an increase in the rate of oxygen absorption and carbon dioxide liberation, the value of the respiratory quotient decreasing. Non-reducing sugar and acid-hydrolysable polysaccharide are rapidly metabolized. Possible explanations of these several phenomena are discussed in some detail. An explanation along the lines that the addition of ammonia to nitrogen-starved cells, which leads to the synthesis of amide, may result in the increased utilization of a substance such as adenosine triphosphate, and hence in an increased respiration-rate, is favoured.

East African Agriculture and Forestry Research Organization: Report for 1952

The report for 1952 of the East African Agriculture and Forestry Research Organization is the first to be issued by the Organization from its new headquarters at Muguga, Kenya. In spite of the unrest in Kenya, considerable progress has been made and three new sections—namely, forest entomology, soil microbiology and soil physics—were opened. The first of these is undertaking a general survey of forest insects and investigating methods for preventing damage from the Cerambycid beetle, which causes serious losses in the exotic plantations of Kenya. Questions of nitrogen supply form the initial programme of the soil microbiology section, while the work of the soil physics department will be based chiefly on soil moisture problems as they affect both agriculture and forestry. In this connexion the recent survey carried out by Dr. C. R. Hursh, of the Southeastern Forest Experiment Station, United States Forest Service, on forest management in East Africa in relation to local climate, water and soil resources, is of special interest. In his report he instances cases where excessive felling of high forest has reduced the mist regarded as desirable by tea growers, and of land deterioration through faulty management of water supplies or overgrazing, and stresses the need for technological development of the results of scientific research if the remaining natural resources of the country are to be safeguarded. The sectional reports show that a healthy co-ordination is in operation both between the various departments within the East African Agriculture and Forestry Research Organization itself, and also with other neighbouring research organizations.

Quartz Clocks of the Greenwich Time Service

A general account of the development of the quartz clocks of the Greenwich Time Service, from the time of the installation of the first quartz clock in 1939 up to the present time, is given in a paper by H. M. Smith (*Mon. Not. Roy. Astro. Soc.*, 113, 1; 1953). It is nearly ten years since the quartz clock completely displaced the pendulum clock in the fundamental work of the Greenwich Time Service, and it has now attained a high standard of reliability. Introduced at first in the Greenwich Time Service as long-term standards, their high stability over periods of two or three years has made it possible to use them for determining the nature of the annual fluctuations in the rotation of the earth. It is worth noticing that the periods of uninterrupted run, given continuity of power supplies, may extend over several years, as has been the case with some of the clocks mentioned. Failure of crystal oscillators is very rare—in six years since the Abinger clocks were transferred to battery operation there has been only one failure of a crystal oscillator.

Index of Theses for Higher Degrees at British Universities

In a paper prepared for presentation to a conference of the Association of Special Libraries and Information Bureaux which was to have been held at Nottingham during September 1939, Colonel Luxmoore Newcombe discussed the accessibility of British university theses and the need for more information about such theses, and went on to raise the question of the feasibility of compiling and publishing a national guide to such theses. Fourteen years later, as a result of discussions of a joint subcommittee appointed early in 1950 by the Library and Information Committee of Aslib and the University and Research Section of the Library Association, this suggestion has come to fruition in a new serial publication of Aslib, "Index to Theses Accepted for Higher Degrees in the Universities of Great Britain and Ireland" (Vol. 1, 1950–51; pp. xii+157. London: Aslib, 1953; 25*s*., or 21*s*. to members). This first volume, which is edited by P. D. Record, covers the academic year 1950–51, except for the University of London, where entries are based on the calendar year 1950. The material has been supplied by the Secretary to the Committee of Vice-Chancellors and Principals, and the Index covers theses accepted by universities in England, Wales, Scotland, Northern Ireland and the Republic of Ireland. Information on availability is summarized in a table appended to an editorial note, and an introduction is contributed by Mr. J. H. P. Pafford. The present volume covers 2,182 theses, and the entries are numbered serially and arranged by subjects, the author's name being given first, followed by the title and the degree for which it is given. The author's university is indicated by an initial letter or letters in parentheses, following his name. An index of authors and a subject index are provided; but the latter, like the classification of the entries, as the editorial note emphasizes, is subject to the hazards and limitations imposed by the absence of any other information as to content beyond that supplied by the titles of the theses.

Radio Instruments and Preferred Valves

The firm of Marconi Instruments, Ltd. (St. Albans, Herts), has recently published a bound catalogue describing and illustrating a large variety of its instruments for those engaged in telecommunications and allied industrial applications. This catalogue is the first of an annual series, and it supersedes the loose-leaf versions which have been issued by the company during the past few years. Among the new instruments described in the present volume are: a series of portable absorption-type frequency-meters covering the range 250–4,000 Mc./s.; a very-high-frequency test set, comprising a signal generator covering frequencies 60–200 Mc./s., power meters for audio and radio frequencies, a radio-frequency field detector, and a multi-range D.C. test meter; and a useful oscillator providing a signal power of about 10–50 mW. over the frequency-range 2,100–3,750 Mc./s. Most of the instruments shown in the section on "Television and Radar Test Equipment" are new, and they include a test set for the 3-cm. band (9,000–9,680 Mc./s.), and a spectrum analyser and noise generator for the 10-cm. band (2,900–3,150 Mc./s.). In order that users of this catalogue may keep up to date with developments in measuring technique, a useful bulletin entitled "Marconi Instrumentation" is issued at frequent intervals and may be obtained on request.

Another most useful publication, which has recently become available, is a booklet entitled "List of Preferred Valves", which has been issued by the Scientific Instrument Manufacturers' Association (20 Queen Anne Street, London, W.1). This comprises in tabular form details of the types and characteristics of a series of valves which, it is believed, will meet most of the needs of those engaged in the scientific instrument industry. The list is divided into two categories—standard-sized valves and miniature valves—and details of the base-connexion arrangements for each type are included.

"Life in A.D. 2000": Royal Society of Arts Bicentenary Competition

The Royal Society of Arts will reach its bicentenary in March 1954, and as part of the celebration of this event the Society is organizing an essay competition with prizes of £250, £100, £50 and ten of £10, making a total of £500. The general subject for the essays is: "The Practical Aspects of Life on this Earth in the Year 2000", and individual competitors are required to submit their forecasts of a single aspect of life at that period related to arts, manufacture or commerce. Entries may be in written or be in visual form (drawings or models, with any necessary explanation in writing); in the former case they must be typewritten and in English and must not exceed three thousand words. The competition is open to all persons of British nationality and Fellows and Associates of the Society of whatever nationality. Competitors must complete an entry form by February 15, 1954, and must submit their essays by June 30. Further details can be obtained from the Secretary, Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2.

History of Regional Farming in Britain

The Association of Agriculture and the British Agricultural History Society are arranging a one-day conference to discuss regional history with special emphasis on the agricultural background, to be held at the Institute of Education of the University of London, Malet Street, London, W.C.1, at 10.30 a.m. on December 5. The first paper will be a general one on "Regional Farming in England", by Dr. W. G. Hoskins. The afternoon session will be devoted to three short papers on "The Farming Regions of Lincolnshire", by Mrs. I. J. Thirsk; "The Rise of Sheep Farming with the Great Enclosures in North Wales", by Prof. R. Alun Roberts; and "Farming Regions with Special Reference to Wiltshire", by

Dr. E. Kerridge; each paper will be followed by discussion. The conference fee will be 5*s*. (2*s*. 6*d*. to members of either of the two organizing bodies). Applications should be sent to the General Secretary, Association of Agriculture, 238–240 Abbey House, 2 Victoria Street, London, S.W.1, or to the Secretary, British Agricultural History Society, Museum of English Rural Life, 7 Shinfield Road, Reading, Berks, from whom further details can be obtained.

Radioisotope Conference at Oxford

A Radioisotope Conference, arranged by the Atomic Energy Research Establishment, Harwell, is to be held in Oxford during the week July 19–24, 1954. This will be similar to a Conference arranged by Harwell in 1951 in Oxford, which was also on these peaceful uses of atomic energy, and was attended by more than five hundred delegates from Britain and many countries overseas. Great progress has been made since then in the use of radioactive isotopes, and the forthcoming Conference will deal solely with developments in recent years. It will discuss methods and results obtained using radioisotopes in all fields of science. On the first three days of the Conference, papers presented will deal with applications in medicine, biology and agriculture. The remainder of the meetings will be concerned with chemical, physical, engineering and general industrial applications. In medicine it is the intention to deal with experimental rather than routine uses. An exhibition of instruments and techniques of interest to radioisotope users will be held in Oxford during the Conference. The printed proceedings will be published, if possible, before the end of 1954. Further details and application forms can be obtained from the Conference Secretary, Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Christmas Lectures for Young People

At the Royal Institution, 21 Albemarle Street, London, W.1, the 124th course of six lectures "adapted to a juvenile auditory" will be given by Mr. J. A. Ratcliffe, of the Cavendish Laboratory, Cambridge, on December 29 and 31, 1953, and January 2, 5, 7 and 9, 1954, at 3 p.m. The general title of Mr. Ratcliffe's lectures will be "The Use of Radio Waves", and he will deal respectively with radio waves and their use for communication; position-finding by radio; radio searchlights and telescopes; radar; the ionosphere; and radio astronomy. The fee for the lectures will be £1 (£2 for adults) and application for tickets should be made to the Royal Institution at 21 Albemarle Street, London, W.1. The Institution of Electrical Engineers (Savoy Place, London, W.C.2) has arranged for Dr. J. H. Mitchell to give a lecture at 3 p.m. on December 31 and again on the following afternoon. Dr. Mitchell will talk on "Electricity through Gases". Admission to the lecture, which is free, can be obtained by writing to the Institution at the above address.

The Night Sky in December

New moon occurs on Dec. 6d. 10h. 48m., U.T., and full moon on Dec. 20d. 11h. 43m. The following conjunctions with the moon take place: Dec. 2d. 04h., Mars 7° N.; Dec. 3d. 12h., Saturn 8° N.; Dec. 4d. 21h., Mercury 7° N.; Dec. 5d. 10h., Venus 5° N.; Dec. 19d. 23h., Jupiter 3° S.; Dec. 30d. 23h., Mars 7° N.; and Dec. 31d. 02h., Saturn 8° N. In addition to these conjunctions with the moon, the following conjunctions with bright stars occur: Dec. 7d. 02h., Mars in conjunction with Spica, Mars 3·5° N.; Dec. 12d. 07h., Venus in conjunction with Antares, Venus 5·2° N.; and Dec. 16d. 09h., Mercury in conjunction with Antares, Mercury 5·4° N. Mercury is a morning star, rising at 5h. 45m. and 6h. 40m. on December 1 and 15, respectively, but later in the month it is too close to the sun for favourable observation. Venus, a morning star, rises at 6h. 25m., 7h. 10m. and 7h. 45m. at the beginning, middle and end of the month, respectively, but at the end of the month this occurs about twenty minutes before sunrise; the stellar magnitude of the planet is −3·4; 0·97 of the illuminated disk is visible at the beginning of the month, and practically the whole towards the end of December. Mars, a morning star, rises about 2h. 55m. throughout December; early in the month it is fairly close to θ Virginis, and towards the end of the month it is near κ Virginis. Attention has already been directed to its conjunction with α Virginis on Dec. 7d. 02h. Jupiter rises in the afternoon and is visible throughout the night, stellar magnitude −2·3. At the beginning of the month it is close to ζ Tauri, from which it slowly moves westward, and on December 13 it is in opposition. Saturn, a morning star, rises at 4h. 30m., 3h. 40m. and 2h. 45m. on December 1, 15 and 31, respectively. In the early part of the month it is a little south of κ Virginis, from which it gradually recedes in an easterly direction during the remainder of the month. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Dec. 1d. 6h. 05·1m., *q* Virg. (*R*); Dec. 11d. 18h. 31·9m., λ Capr. (*D*); Dec. 24d. 23h. 36·3m., 88 *B* Leon. (*R*). *R* and *D* refer to reappearance and disappearance, respectively. The Geminid meteors, radiant near α Geminorum, are active during December 11–13. Winter solstice occurs on Dec. 22d. 04h.

Announcements

H.R.H. the Duke of Edinburgh has graciously consented to accept honorary membership of the Institution of Mining Engineers.

The theme for the next annual meeting of the Société de Chimie Physique, to be held in Paris during June 8–12, 1954, will be "The Structure and Texture of Catalysts". Those wishing to read papers should submit a short résumé before January 15 and the text before March 15, so that they can be printed and circulated in advance of the meeting. Further details can be obtained from the secretary-general, Prof. G. Emschwiller, École Supérieure de Physique et de Chimie, 10 rue Vauquelin, Paris 5e.

Errata. In the communication entitled "Birefringence and Elasticity in Keratin Fibres", by Dr. R. D. B. Fraser, published in *Nature* of October 10, p. 675, it is incorrectly stated that birefringence values could be reduced to a common density by use of the factor $\sqrt{\rho_0/\rho}$; this factor should be ρ_0/ρ. The expression used for calculating birefringence gives only a partial correction for density variation. Line 12 should read ". . . in birefringence during extension . . ."; and the legend to the graph should read ". . . 30 per cent and 50 per cent extensions of human hair".

INTERNATIONAL CO-OPERATION IN AFRICAN BOTANY

SOME seventy members and guests of the Association pour l'Étude Taxonomique de la Flore d'Afrique Tropicale held their second plenary meeting at Oxford during September 29–October 3. The full text of the scientific papers read will be published in Florence in the journal *Webbia*, under the editorship of Prof. R. E. G. Pichi-Sermolli. The following is a brief account of some of the more important results.

After the introductory address of welcome by the president, Mr. A. W. Exell (British Museum, Natural History), Dr. W. Mullenders (Brussels) read a paper on "The Phytogeographical Elements and Groups of the Region of Kaniama (High Lomami—Belgian Congo)". He stated that it is possible to analyse floras according to the phytogeographical groups represented: first, the basic element characteristic of the region dealt with; secondly, connecting groups characteristic of two or several regions; thirdly, pluri-regional groups (palæotropical, pantropical and cosmopolitan); and fourthly, endemics. Dr. Mullenders on this basis made an analysis of the flora of the region of Kaniama (841 species), using the phytogeographical territories established by Lebrun. He found that 31·3 per cent (263 species) belonged to the Guinean element and 31·4 per cent (264 species) to the Sudano–Zambesian element. Plants of the connecting groups comprise 15·3 per cent (129 species); endemics 1·7 per cent (14 species); and species widely spread 20·3 per cent (171 species). The connecting groups showed a decided bias in favour of the Guinean region. The Guinean element was highest in the wetter grass communities and lowest in the dry grass communities, and conversely with the Sudano–Zambesian element. Degradation by fire led to reduction of the Guinean element, while absence of human interference favoured the development of equatorial forest, with, of course, a high proportion of Guinean species. The climax is thus mainly represented by the Guinean element, but the impact of man tends to favour Sudano–Zambesian species. The Kaniama district is thus to be placed in the Guinean region, though close to the boundary of the Sudano–Zambesian region.

Dr. Hugh Scott described and vividly illustrated an adventurous journey to northern Ethiopia, particularly the mountainous High Simien, during November and December 1952, mainly to study the insect fauna of high elevations. His route was from Asmara across the Tacazzé River to Debárec and thence to the High Simien, Gondar and Lake Tana. He visited Mt. Buahit (14,796 ft.) and Ras Degien (15,154 ft.), the highest peak in Ethiopia. On the latter, *L. rhynchopetalum* and the spiny *Helichrysum citrispinum* were characteristic of high altitudes. Here true snow occasionally falls; but Dr. Scott only encountered frozen hail. Among other plants illustrated were tree-heath, bamboo, a giant *Echinops* and *Kniphofia*. The only giant lobelia was *L. rhynchopetalum*, the hollow stems of which are used as trumpets; *L. giberroa*, so abundant in parts of central and southern Ethiopia, and also in Eritrea, was not seen. The top of the plateau of the High Simien has been mostly cleared, but juniper trees around churches give evidence of its original vegetation. No *Podocarpus* was seen.

Dr. J. Léonard (Brussels) directed attention to the difficulties encountered in interpreting large heterogeneous genera—whether to maintain them and at the same time perpetuate bad taxonomy, or to put them in order by making them homogeneous. In order to divide heterogeneous genera, it is necessary to take into account the hierarchy of characters, to study all the species, and to assess the correlation of characters, which may be primary characters derived from the morphology of the flower, or secondary characters which are vegetative and often minor but nevertheless most useful. Good genera should have correlation between primary and secondary characters. Genera with primary characters only are doubtfully valid, and with secondary ones only even more suspect. Where secondary characters are in opposition within a genus, it may imply the existence of overlooked primary ones. He emphasized the need of uniformity in the treatment of genera.

Species of the savannah and miombo are often extremely variable and thus to some extent subjective, while in forest species there is, on the other hand, a tendency to fixity of characters, thus making the species objective. Bad taxonomy and a mixture of species is often implied by a very variable forest species, or by geographical or ecological discontinuity. Dr. Léonard gave examples in the genera *Guibourtia* and *Afzelia*. He finally emphasized the need for systematists to study all available material of a group.

Prof. P. Duvigneaud (Université Libre, Brussels) then discussed "La Géographie des Caractères et l'Étude de la Flore Africaine", with special reference to the Soudano–Zambesian region. When the flora of this region was being first described, there was little material available, and in some groups further collections have served to link up the earlier described species in a remarkable way, so that to-day certain species prove to have a range of variation much greater than was originally thought possible. He went on to analyse geographically this range of variation in certain groups, notably in *Erythrina*, *Diplorrhynchus* where six described species were shown to be referable to only one with geographical sub-species, and the suffrutiocose species of *Cryptosepalum* where there is a quite extraordinary range of variation. He contrasted these genera with others where similar characters have proved to be not only quantitative but qualitative as well and have served to define good species. Prof. Duvigneaud went on to discuss the reasons for the extraordinary range of variation found in some groups, suggesting that it might be due to past climatic changes and introgressive hybridization favoured by a uniform topography. He emphasized the necessity of examining the entirety of material of a species before deciding upon the limits of its variation.

The morphology of the African species of *Loranthus* was considered by Mlle. S. Balle (Université Libre, Brussels). In the African continent some three hundred species are found, belonging to thirty-two well-characterized groups or sections. The morphological characters of taxonomic importance are mainly derived from the flowers, which show a wide range of structure, the perigone being either gamo- or poly-petalous, mostly zygomorphic, but sometimes actinomorphic, with 4–7 segments; the stamen filaments may be erect, reflexed or curled, with or without a tooth, and may show thickening above.

The morphology of the style also varies. Mlle. Balle compared the characters of groups represented in Africa and those represented in Asia and Oceania. She then analysed the distribution of the different sections in different territories in Africa according to their degree of evolution, finding that the most primitive sections are poorly represented or absent in West Africa but much better represented in East Africa. She finished by posing the problem of whether to maintain *Loranthus* as a single genus or to split it up into a constellation of smaller genera.

Mr. F. White (Imperial Forestry Institute, Oxford) then discussed "The Distribution of some African Species of *Diospyros*", the largest and most widespread genus of the Ebenaceae, agreeing with the rejection of *Maba* as a distinct genus. Though *Diospyros* grows in every territory and climatic zone of Africa except the very driest, he presented evidence to indicate that it is essentially a forest genus. He also directed attention to the concentration of species in the coastal forests of East Africa, where fourteen species occur of which eleven are endemic; nine of the latter have no close affinity with other species of tropical Africa, though two are very closely related to West African species. He gave further examples of vicarious species in East and West Africa.

In a paper on "Pollen Morphology and Taxonomy of Certain African Plants", Prof. G. Erdtman (director of the Palynological Laboratory, Stockholm) showed for the first time some electron micrographs of ultra-thin sections (200 A. thick) of pollen grains and spores prepared by a special technique, mainly developed by Dr. Sjöstrand (Stockholm). He then went on to describe various instances among African plants where pollen morphology gives valuable support to taxonomic views already expressed, or makes new suggestions which the taxonomist must consider. The validity of the following families, Dioncophyllaceae, Ctenolophonaceae and Barbeyaceae, is thus confirmed. Other suggestions were that Canellaceae may be related to the Magnoliales; that *Pentadiplandra* has pollen similar to that of Capparidaceae, but not to that of the Olacales; that *Jollydora* is anomalous in Connaraceae; that *Craterogyne* is distinct from *Trymatococcus*; that *Choristylis* and *Itea* have similar pollen and may constitute a separate family; that *Roussea* and *Ribes* have fairly similar pollen grains; that *Kirkia* is anomalous in Simaroubaceae; and that an affinity for Thymelaeaceae is to be sought among the crotonoid genera of Euphorbiaceae. Prof. Erdtman finally directed attention to the recently formed International Commission on Palynology and asked that polliniferous or sporiferous material of species of new genera, sub-genera, etc., should be sent to him when they are described, in return for a diagnosis of the pollen grains or spores.

Dr. R. A. Maas Geesteranus (Rijksherbarium, Leyden) discussed two features concerning the lichens of Kenya. *Xanthoria parietina*, common in the northern hemisphere in nitrogenous or maritime habitats, is also found in North Africa, at the Cape and in a few stations in Kenya at about 2,000 m. altitude, which may be connected with neighbouring soda lakes the dust of which is often widely dispersed by wind. His second topic was the development of lichens in the bamboo zone and the way in which they colonize old bamboo stems, starting at the internodes with crustaceous species, which can survive on atmospheric moisture and retain it, and are then followed by foliaceous and fruticose species. The internodes are ultimately invaded from the nodes.

The nomenclature of the vegetation zones on the mountains of tropical Africa was considered by Prof. A. S. Boughey (University College, Achimota), who pointed out the extraordinary duplication of names given by different authors for the same community, and emphasized the need for some uniform system. He suggested a division into zones rather than belts —since the latter imply too much spatial continuity— using floristic differences as a basis, delimited by differences in altitude. He proposed the following six zones: lowland, 0–800 m.; foothills, 800–1,500 m.; highland, 1,500–2,100 m.; montane, 2,100–3,000 m.; temperate, 3,000–4,500 m.; and mountain desert, above 4,500 m. He finished by comparing these proposed zones with those used by Prof. C. G. G. J. van Steenis in Malesia.

Prof. L. Hauman (Brussels) read a paper, "Sur la Nécessité de distinguer une Région afro-alpine pour la Végétation africaine". The high mountains of East Africa are equatorial, and thus the temperatures of their high altitudes are uniformly low. Their high altitudes are isolated climatically and poor floristically, but what plants there are are often remarkable, for example, the giant senecios and lobelias. The genera include many that are temperate but apparently none endemic. Continual cloud causes a great richness of bryophytes. Prof. Hauman proposed to consider the vegetation from the zone of giant lobelias and senecios upwards as constituting the Afro-alpine Zone, lying above the sub-alpine zone of heath-forests.

Dr. O. Hedberg (University of Uppsala) dealt with "Some Taxonomic Problems concerning the Afro-alpine Flora", commenting that no allowance for range of variation was made when species were described in the past. By graphical methods he showed continuous variation in such genera as *Sebaea* and *Swertia*, resulting in the reduction to synonymy of numerous species previously considered distinct. In these genera, he said, the idea of vicarious species inhabiting different mountains in tropical Africa has been pushed too far on insufficient evidence. He then gave examples of wide variation within one species shown by *Senecio keniophytum* and *Helichrysum citrispinum*. He also pointed out that insufficient allowance has been made for hybridization, which certainly occurs among the genera *Senecio* and *Lobelia*, and gave a graphical analysis of hybrid populations between two herbaceous species, *Senecio mattirolii* and *S. transmarinus*, demonstrating that certain previously described species are, in fact, elements of a hybrid swarm between these two. He finally announced that he is engaged on a complete revision of the alpine flora of the East African mountains.

Mr. J. B. Gillett (Royal Botanic Gardens, Kew), who has recently returned from southern Ethiopia, considered the relation between the highland flora of Ethiopia and that of Kenya Colony, with reference especially to recent statements that the Ethiopian highlands form a different phytogeographical region from those of East Africa. Mr. Gillett divided a sample of the flora of the southern margin of the Ethiopian highlands into four groups, as follows: (*B*) plants confined to Ethiopia south of 10° N.; (*AB*) plants also found in the highlands of British East Africa; (*BC*) plants found in northern Ethiopia; and (*ABC*) plants found in all three areas. The totals are: (*B*), 10; (*AB*), 41; (*BC*), 12; and (*ABC*), 112.

These figures indicate that the flora of the southern Ethiopian highlands is more closely related to that of the British East African highlands than to that of northern Ethiopia, in spite of the formidable obstacle to the spread of highland plants now presented by the low arid country of northern Kenya.

In a paper on "Some Aspects of the Vegetation of Ruwenzori", Mr. R. Ross (British Museum, Natural History) gave some observations made on the recent expedition to Ruwenzori of which he was a member, discussing particularly the zonation of vegetation. He recognizes the following zones: 1,200–2,100 m., *Pennisetum* savannah. 2,100–2,600 m., montane forest: probably complex, much affected by climatic and biotic factors—for example, elephants. 2,600–3,100 m., bamboo zone: divisible into four topographical types, two characterized by Ericaceae, thus simulating the true ericaceous zone higher up. 3,100–3,300 m., *Rapanea-Hagenia* forest: a tree lobelia and senecio occur. 3,300–3,900 m., ericaceous zone: *Philippia longifolia* forest dominant, mostly about 10 m. high, sometimes less; a bog vegetation of tree senecio and lobelia occurs, to be distinguished from similar communities higher up. 3,900–4,800 m., alpine zone: a mosaic of *Alchemilla* heath, *Helichrysum* scrub and tree senecio forest; these may be intermingled where the soil is continually wet. Above 4,800 m., glaciers.

Mr. Ross particularly noticed a repetition at different altitudes of communities similar in appearance but floristically different.

J. P. M. BRENAN

GENETICS AND PLANT PATHOLOGY

THE breeding of resistant strains offers a valuable means of reducing the loss of production caused by disease in our domestic plants; but if his work is to be efficient and successful the breeder must enjoy the co-operation of the plant pathologist. A welcome opportunity for a joint discussion of their common problems was provided for pathologist and breeder at the meeting of the British Mycological Society held at Birkbeck College, London, on October 16. The subject was "Genetical Aspects of Plant Disease" and the chair was taken by Dr. C. J. Hickman.

In the introductory paper, Prof. K. Mather sketched in the nature of the host–disease relation from the genetical point of view. Host and pathogen are in permanent conflict: resistance in one puts a selective advantage on virulence in the other, while virulence in its turn puts a premium on new resistance. The situation is seen almost diagrammatically with bacteria and their phages. Exposure to the phage will select out the few resistant mutants from a colony of susceptible bacteria. The resistant colonies grown from these will in their turn select out mutants with new powers of attack from the, to them, otherwise innocuous phage; and so on. In bacterium and phage these changes are attributed to fresh mutation, but in higher plants and fungi a store of variation exists as a permanent feature of populations and species, both in the wild and in domestication. The variation affects properties of resistance and pathogenicity as well as all the other characters, morphological and physiological, of the plant, so that the selection of new mutant forms of the crop or virulent strains of the disease need not wait on the chances of mutation.

The mode of storage of the variability and its availability to selection depend on the system of variation of the species. In crop plants it may exist within varieties where cross-breeding is the rule, or between varieties of inbreeders, or in wild relatives of the domestic species. The breeder may draw on any of these for the raw materials of improved resistance. The systems of variation in fungi are less well understood; but there can be little doubt that variation for pathogenicity is common in the wild. The variation may be stored by genic balance within nuclei and released by sexual recombination, or it may be hidden by balance between nuclei in heterokaryons and released by sorting out in asexual spore production. The reaction of the fungal population in producing new pathogenic strains to the introduction of resistant host varieties must clearly depend on the system of variation. A fuller understanding of these systems in fungi is therefore a prime requisite for an adequate programme of breeding for disease resistance.

Mr. E. W. Buxton then gave an account of his investigations into the variation of *Fusarium oxysporum*, the imperfect fungus which causes the yellows disease of *Gladiolus*. Variation was observed in respect of both morphological characters and pathogenicity in cultures of the fungus isolated from diseased *Gladiolus* plants. Although some mutation appears to occur, it is too infrequent to account for the variation to be seen in the cultures, which must therefore have been present in the original isolates from the host plants.

While the older cells of the hyphæ generally contain but one nucleus, the tip cells have an average of seven nuclei, and anastomoses are common between adjacent hyphæ. Thus all the requirements for the formation of heterokaryons are present, and heterokaryons can indeed be readily synthesized in experiment. The nuclear ratio of a heterokaryon has been shown to vary characteristically with the carbon content and carbon/nitrogen ratio of the medium on which it is grown, adjustment to the medium taking place in a matter of a few days. There can be little doubt that heterokaryosis is an important factor in the storage of variation for morphological characters, and that it has complicated the taxonomy of this fungal group. Though there is less experimental evidence about variation in pathogenic properties, such variation undoubtedly occurs in the wild and it appears to be uncorrelated with the morphology of the fungus. Heterokaryosis may well be important also in regard to these pathogenic properties, and a number of questions, such as whether the hyphæ in the soil and those which invade host tissues are heterokaryotic, suggest themselves for further study.

The third paper, by Mr. P. R. Day, also dealt with an imperfect fungus, *Cladosporium fulvum*, which is a serious pest of the tomato. Three resistance genes are known in the tomato, so that 2^3 physiological races of the fungus can be distinguished by all-or-none tests of infectivity. Of the eight possible races, seven have been recognized in Canada and five of these have been found in Britain. The fungus may be heterokaryotic but inoculation tests have so far proved inconclusive and the controlled synthesis of a heterokaryon has yet to be achieved. Marker mutations have been induced in the fungus by irradiation but, perhaps for technical reasons, no mutation affecting pathogenicity has yet been found, even though loss mutation could bring about specialization should immunity of the host spring from a reaction induced in it by the attacking fungus. The radiation-induced markers were used to follow the effects of competition in a susceptible host between races of the fungus differing in their levels of host specialization. It has been claimed that, in the blight fungus, races with wider host ranges have lesser virulence—a relation which would be of great importance in the conservation of variation in natural populations—but the results with *Cladosporium* were not fully consistent. Mr. Day concluded by suggesting the growing of genetically mixed stands of host plants to control the spread of the disease fungus.

The remaining two papers took up the story from the point of view of the host crop. Dr. H. W. Howard described work on breeding potatoes for resistance to disease, especially late blight. In first reviewing the general considerations which the plant breeder must have in mind, Dr. Howard pointed out that a decision must be taken as to which of the many diseases must be given pride of place in the breeding programme; that sources of resistance must be sought within the crop itself and in wild relatives; that some knowledge of the genetics of resistance is valuable, though it need not be precise; that easy methods of testing resistance are desirable even though not essential; and that a knowledge of variation in the pathogen is essential but may not come along until resistant varieties of the host plant are available.

Cultivated potatoes differ quantitatively in their degrees of attack by late blight (*Phytophthora infestans*). The related species, *Solanum demissum*, is field immune in Great Britain, though it suffers from blight attacks in its native Mexico. Up to now blight resistance has been sought by the transfer of major genes for resistance from *S. demissum* to the potato. These varieties of potato with new properties of resistance, however, tend to go down under the attack of new physiologic strains of the fungus showing the specialization necessary for the successful attack of the new varieties. Indeed, where mixed stands of potatoes have been grown, they have served to reveal the simultaneous presence of all the strains of fungus necessary to attack the host plants with their various types of resistance. Thus the variation for pathogenicity is present in the natural population of the fungus, perhaps as a simple mixture of genetic types, perhaps in heterokaryons. Immediate mutation can scarcely account for the presence of the many strains, for although occasional mutation of type has been seen in culture, the fungal strains are in general stable in respect of their pathogenic properties. But whatever the way in which these fungal strains appear, the future of the *demissum*-type of resistance in potato breeding is far from certain: it may have to be reinforced, or even replaced, by selection of the quantitative type of resistance found in *tuberosum* itself.

The fifth and last paper of the meeting was a fascinating account of his work in breeding strawberries resistant to the red core fungus, *Phytophthora fragariae*, by Mr. R. D. Reid. When the breeding work was started it was not even known with certainty that red core was due to a *Phytophthora*. With the isolation and description of the fungus by Dr. Hickman, the first great step forward was taken. Mr. Reid then described how he had sought for sources of genetic resistance, how these had been found despite many disappointments and difficulties, and how the resistance had been combined with good plant characters; how specialized races (of which some ten have now been identified at least tentatively) have appeared in the picture, and how the search for sources of genetic resistance is still going on with the aim of using them to keep the strawberry ahead of the fungus. Again the question, as yet unanswered, of the origin and rise of the new strains of fungus is at the centre of the breeder's problems.

Discussion was opened by Mr. G. G. Samuel, who began by pointing out the great economic importance of breeding for disease-resistance. Biffen's wheats and Reid's strawberries, for example, show what immense rewards can result from successful breeding—at least for the grower if not for the breeder. Great needs still exist: the breeding of potatoes able to stand up to the root eelworm could, for example, save up to £2,000,000 a year in the potato crop of Britain. Genetics—in the present connexion fungal genetics, particularly Jinks's study of heterokaryosis—is now coming to the aid of the breeders seeking to produce disease-resistant types, and it promises to be an ally of the utmost value. But, despite the breeding successes of the past, are we working on the necessary scale? Where we now work in thousands, should we not think in terms of, and plan for, tens and even hundreds of thousands of seedlings annually, as do breeders in some other countries? Should we not aim at a bigger effort? A general discussion, ranging over such diverse topics as the genetical requirements of mycologists, technical aspects of assessing disease resistance and methods of controlling the spread of new pathogenic strains of fungi, then concluded the meeting. K. MATHER

RECRUITMENT FOR THE CIVIL SERVICE

REPORT OF THE COMMISSIONERS FOR 1949–52

AT the Universities and Industry Conference organized by the Federation of British Industries at Ashorne Hill in October 1952, Sir John Maud expressed the view that, although the Civil Service requires a larger proportion of first-class graduates than it has been having, it is probably in the national interest that more, at any rate, of those of marginal first-rate standard should go into industry or trade rather than into the Civil Service. The report of the Civil Service Commissioners for the period April 1, 1949–March 31, 1952*, suggests that this may now be happening. At the beginning of the period the Commissioners did not find enough candidates of good quality for the administrative class. Although afterwards there was no difficulty in filling the vacancies—about sixty each year—throughout the period, they were unable to fill all the vacancies in the senior branch of the Foreign Service and in the special departmental classes (mainly inspectors of taxes), in which there were more posts to be filled than before the War. The Commissioners have formed the general impression that the number of outstanding candidates who wish to join the Home Civil and Foreign Services is smaller than it used to be. Throughout the period they were unable to fill all the available posts in the scientific classes, and for most of the period all the growing requirements of departments for the professional engineering and analogous classes could not be met. The biological field was the only one in which the number of good candidates was larger than the number of vacancies; but even here all the posts could not be filled since some of them required specialized ability and training. The general standard of the candidates accepted was good; but there were not enough of really first-class quality suitable for the most exacting kinds of original work.

---

* Report of Her Majesty's Civil Service Commissioners for the Period 1st April, 1949, to 31st March, 1952. (Being the Eighty-Fifth Report of the Commissioners.) Pp. 61. (London: H.M.S.O., 1953.) 2s. net.

The system of continuous recruitment, previously tried and now adopted in all competitions for the senior scientific officer and scientific officer classes, under which candidates could apply at any time during the year, has been extended to the recruitment of professional engineers, surveyors and architects, with a consequent improvement in the position; and by further substantial salary increases and raising the upper age-limit to sixty, a sufficient number of good candidates was attracted by the beginning of 1952 to fill the reduced number of posts available, apart from those for quantity surveyors. Evidence of the diminished appeal of the Civil Service to the scientific worker or technologist is to be seen, however, in the figures given for the competitions for the scientific classes for 1949–50 and 1950–51. During the former year there were some 211 applications for 30–40 posts as senior scientific officer, of whom 115 were interviewed or examined and 40 were accepted. For 1950–51 there were 262 applications for 77 posts, but only 109 were interviewed and 51 accepted. For scientific officers the trend is the same: during 1949–50, 1,196 applications for 265 posts, 745 interviewed and 285 accepted; during 1950–51, 610 applications for 398 posts, 338 interviewed and 158 accepted; and during 1951–52, 212 applications for 85 posts, 97 examined or interviewed and 59 accepted.

There is as yet little evidence on which to judge the value of the new selection methods for the administrative class. The details of the place of education and the university degree of successful candidates for the administrative class in the Home Civil Service and the senior branch of the Foreign Service during 1949–52 indicate that the new methods have made little difference to the social structure of the Service. A wide range of public and grammar schools is represented; but few schools provide more than one entrant a year. In the Foreign Service, Oxford and Cambridge are much more dominant among the universities in providing recruits than they are for the Home Civil Service. This wide distribution of schools providing candidates is possibly encouraged by the depreciation inseparable from the expansion of officialdom; but relatively lower salaries, overwork and a belief which is encouraged, for example, by Treasury parsimony on pension adjustments, that the State is a poor, if safe, employer, may well be important factors in lowering the attractiveness and prestige of the Civil Service.

The Commissioners' report includes one example of official dilatoriness which indicates the seriousness of such factors. In 1949 the Government decided to create a small new general-service class of information officers, and during 1949–50 some 279 candidates were interviewed and 242 appointed. A special competition to fill 80–90 posts in all grades of the class was announced in June 1951. About three thousand applications were received, and 466 candidates were interviewed. "It has not yet been possible," states the report, with unconscious irony, immediately in front of a paragraph dealing with psychologists, "to announce the results of this competition, since the future of the Information Service has come under further review."

INTERNATIONAL SCIENTIFIC ABSTRACTING

The Abstracting Board of the International Council of Scientific Unions came into existence officially on June 1, 1952, but its activities first began about November 1951. A report on its activities to date was presented by the secretary of the Board, Prof. G.-A. Boutry, to the Executive Committee of the International Council of the Scientific Unions for its meeting at Strasbourg during July 9–10, 1953, where the Abstracting Board was itself to meet for the first time. Dispersion of the members of the Board throughout the world has caused some delay without seriously impeding the activities of the Board, apart from secretarial embarrassment, which is likely to persist until the subventions allocated to the Board permit at least one meeting in the year.

A major result achieved by the Board and noted in this report is the formal acceptance of the decisions of the United Nations Educational, Scientific and Cultural Organization and the Royal Society regarding authors' summaries by all periodicals printing papers on physics and published in the United States, the Netherlands, Belgium, France, Italy and, with a few exceptions, the United Kingdom. The Board has also requested the publishers of the more important periodicals printing papers on physics to forward a set of the final page-proofs of each of their issues to one or both of the editors of *Science Abstracts* and the *Bulletin Analytique du Centre National de la Recherche Scientifique* (Paris). This action was at first limited to a few selected periodicals in each country, and the report lists the periodicals which are co-operating in this way in the United Kingdom, the United States, France, the Netherlands, Switzerland, Canada, Australia and Japan, and further periodicals published in France, Italy and India, with the editors of which negotiations are still proceeding. As a net result a delay of six to eight weeks in the appearance of the most important abstracts in these two periodicals has been eliminated.

Measures have also been taken to increase the number of non-periodical publications dealt with. Physical societies have now agreed that, when an advance note of a paper or meeting is published, the account will mention the later publication of the full paper. Non-periodical publications in France will be reviewed by the editor of *Bulletin Analytique*, who will forward to *Science Abstracts* documents he considers should be abstracted, and a reciprocal service for non-periodical publications of the United Kingdom will be undertaken by the editor of *Science Abstracts*. Action is now being taken to extend this work to northern countries and also to cover, where necessary, colloquia and symposia organized under the auspices of the International Union of Pure and Applied Chemistry, though the Board recommends that, whenever possible, papers presented at such meetings should be published in one of the regular periodicals of physics. It is also stated in the report that the *Physikalische Berichte*, which is resuming publication, is to apply for membership of the Board and that Dr. L. H. Lampitt was attending the Strasbourg meeting as an observer on behalf of the International Union of Pure and Applied Chemistry. The lists of periodicals of physics published in the Spanish and Portuguese languages have recently been reviewed, and inquiries made with the view of compiling similar lists for Japan and the northern countries of Finland, Norway, Sweden, Denmark and the Netherlands. It has also been arranged that the Italian periodical *Il Nuovo Cimento* will publish in 1953 an extra number, including ten to twelve articles reviewing the work of Russian schools in certain special branches of physics.

AUTOMATIC GRAIN COUNTER FOR ASSESSING QUANTITATIVELY HIGH-RESOLUTION AUTORADIOGRAPHS

By Dr. R. A. DUDLEY* and Dr. S. R. PELC

Medical Research Council Radiotherapeutic Research Unit, Hammersmith Hospital, London

AN instrument for automatically counting photographic silver grains has been developed to permit the use of high-resolution, low-exposure autoradiography as a quantitative method. It is expected that this extension of autoradiographic techniques to yield quantitative information will greatly increase the value of this method.

The particular autoradiograph technique for which the grain counter has been designed is that in which stripping film is employed[1]. In this method a spatial resolution of about 2 μ can be obtained, through the use of a thin (3–4 μ), fine grain (0·3 μ diameter) emulsion (Kodak, Ltd., *NT2a*), superimposed in intimate and permanent contact over the tissue section. Background is very low.

Of the various possible methods of assessing quantitatively the photographic 'image', automatic grain counting is the most suitable. Microdensitometry is not practical with this emulsion, because density is too low to permit useful measurement. For example, a grain concentration of 6 grains/100 μ^2, which in favourable cases may be two or three times background fog, corresponds to an optical density of only 0·002. In autoradiographs, densities as low as this would be hopelessly masked by variations in background density in other parts of the preparation, such as in the tissue section itself. Experience has shown that the use of larger grains, big enough to give a significant density, would limit the high spatial resolution which is the chief merit of the stripping-film technique. Visual counting of grains is far too laborious as a method of quantitative measurement, except for the most specialized problems. Visual counting of tracks caused by β-particles, a possibility with the more sensitive minimum-ionization emulsions, is even more laborious and subjective than grain counting. Automatic counting of β-tracks is at present too difficult to be considered. The method of choice, automatic counting of grains, has the great advantages of high sensitivity, speed and freedom from subjective error; its one serious disadvantage is the instrumental complexity.

The automatic grain counter which has been built is basically similar to the flying-spot microscope and particle counter designed by Roberts[2]; a detailed technical description will be published elsewhere. In brief, the operation of the instrument is as follows. A scanning spot of light is produced on a television projection tube, placed about 10 in. above the eyepiece of a microscope. This spot sweeps out an ordinary television raster (pattern of closely spaced parallel lines). The raster, projected down through the microscope (thus in the reverse direction from that used in conventional microscopy), is focused on the autoradiograph emulsion placed in the ordinary object plane of the microscope. Both scanning spot and complete raster are reduced in size by a factor equal to the reciprocal of the magnification of the microscope. With an objective having a numerical aperture of 1·3 N.A., the spot diameter can be as small as 0·3 μ, the size of the grains. On the autoradiograph, the full raster covers an area of 50 μ × 50 μ; by masking off part of the projection tube screen, it is possible to limit the scanning to any desired part of the square. Beneath the microscope condenser is a photomultiplier which continuously measures the amount of light passing through the autoradiograph. When the scanning spot crosses a silver grain, which causes 30–50 per cent absorption of the light, the brief interruption of the light beam is converted to an electrical pulse at the photomultiplier output. These pulses are then amplified, sorted according to height, and fed into a scaler. The sorting is performed by a single-channel differential-amplitude discriminator, which eliminates both those pulses which are too small (for example, noise) and those which are too large (for example, 100 per cent extinction of scanning spot during the backsweep of the spot) to be pulses caused by grains. The complete field of view is scanned once every 0·02 sec., but for greater accuracy the count is summed over about 175 successive scans in a period of 3·5 sec.

The automatic count is not absolute, although it can be calibrated by a visual count if desired. The larger grains are probably counted somewhat more frequently than the smaller ones; but this condition can be improved, if required, by careful adjustment of the discriminator levels.

Besides the counting circuits, provision is also made for a flying-spot microscope picture of the area being scanned. This is produced on a television display tube the spot of which traces out a raster synchronized with the projection-tube raster. The output from the photomultiplier controls the instantaneous brightness of the display spot, which therefore 'paints' on its screen a picture of the field of view. A useful visual check on the automatic counting process is provided by arranging that, at the instant a count is recorded by the scaler, a brightening pulse is fed on to the display tube. The picture then shows the silver grains in the field as black dots; those grains which are being counted are followed immediately by a bright dot.

One optical problem in the counting is that the emulsion is too thick for all the grains to be in focus at once. A method of surmounting this problem is to count at several planes of focus, each separated by a small, accurately reproducible distance from its neighbours. Simple depth of focus adjustment is possible by altering the mechanical tube-length of the microscope. If a 95 × objective is in use, lifting the eyepiece 1 mm. raises the plane of focus 0·1 μ.

Experience shows that this adjustment can be carried out, for a range of at least 4 μ depth of focus, without seriously affecting either microscope magnification or aberrations.

The fundamental instrumental difficulty in the grain counter has lain in reducing spurious counts to such a low number that they do not mask true grain counts. The most troublesome source of spurious counts is the inherent statistical fluctuations in the small number of light photons which examines each potential grain site in the emulsion. However, this problem has been satisfactorily solved by careful attention to the signal-to-noise ratio problems throughout the optics and electronics.

A set of preliminary grain-counting tests has been carried out with the instrument. While more experience must be acquired before the performance of the counter can be fully assessed, these first tests have proved that it will fulfil its purpose. Short-term stability is very good. Repeated counts on the same area of film have been made over various periods of time extending up to 1½ hr. In all cases, drifts amounted to less than 2–3 per cent. Sensitivity, in terms of minimum measurable grain concentration, is satisfactory. It was found that the minimum grain concentration ever encountered, namely, fog background of about 2 grains/100 μ^2 (equivalent to a density of 6×10^{-4}), could be reliably measured above the spurious counting-rate. Absorption of the scanning light by the tissue section, unstained or lightly stained, will introduce only second-order interference.

Emulsion sensitivity is sufficiently uniform to make it possible to compare counts on different areas of a single slide. In testing this, automatic grain counts were taken at 27 points over an area of 1 cm. × 3 cm. of a slide uniformly exposed to γ-rays, each count covering a square of 33 μ × 33 μ. The standard deviation of the individual counts was 6 per cent, of which at least a considerable part could be attributed to true statistical fluctuations in grain number.

The magnitude of the automatic grain count is very closely proportional to the exposure of the emulsion. An example is shown in Fig. 1, for which exposures were produced by thick sources of strontium-90 – yttrium-90 incorporated in plaster of paris. Development of the emulsion was carried out for 5 min. at 17·5° C. in *D* 19 *b*. With a counting time of 3½ sec., the automatically counted number of grains per 100 μ^2 is about 80 per cent of the number counted visually. The total height of the vertical line through each point in Fig. 1 is equal to twice the standard deviation in the number of grains counted at that point.

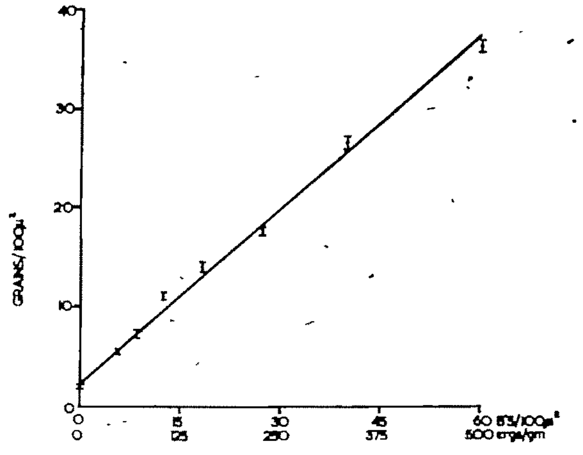

Fig. 1. Plot of automatic grain count *vs.* associated β-ray exposure on *NT2a* stripping film. Exposure is given in absolute units of both dosage and number of β-particles per unit area. Vertical lines through points represent standard deviation based on number of grains counted

We are indebted to Mr. F. Roberts for his generous help and advice, and to Messrs. J. Crawley and T. Davis for technical assistance. [Oct. 1.

THE B-VITAMINS IN WHEAT: THE UNIQUE ALEURONE LAYER

By Dr. J. J. C. HINTON, F. G. PEERS
and Dr. B. SHAW

Research Association of British Flour Millers, Cereals Research Station, St. Albans

THE content of certain nutrients in a flour is determined by the distribution of these factors in the wheat grain and the milling technique used in producing the flour. It is thus important to have precise information as to the distribution of these nutrients in the grain.

The first attempt to separate the various anatomical fractions of the wheat grain for analysis was made by Girard[1], who obtained nitrogen figures for the embryo, endosperm and outer layers. More recently, information has been derived by the examination of the various milling streams, for example, the work of Andrews, Boyd and Terry[2] on riboflavin, Thomas, Bina and Brown[3] on nicotinic acid and Teply, Strong and Elvehjem[4] on nicotinic acid, pantothenic acid and pyridoxin. Such results, however, are not so informative as those obtained by analysis of the anatomical fractions of the dissected wheat grain.

Hinton[5,6] has developed microdissection techniques for the study of the distribution of nitrogen, aneurin and nicotinic acid in wheat var. Thatcher. The present communication extends this work to riboflavin and pantothenic acid. In addition, from assays of folic acid, biotin and pyridoxin in various flours, it is at least possible to suggest the probable distribution of these factors.

The dissections were carried out manually under a low-powered microscope, and the methods used have been fully described elsewhere[6]. The grain was divided into the principal anatomical regions, namely, pericarp + testa, aleurone, embryo, scutellum and endosperm. The factors were assayed by the microbiological techniques described by Barton-Wright[7], with the exceptions of folic acid and aneurin, which were determined by the methods of Jones and Morris[8] and Ridyard[9] respectively. With riboflavin and pantothenic acid, when only small amounts of certain fractions were available for assay, the method of extracting the factor was modified as described for nicotinic acid by Heathcote *et al.*[6].

Riboflavin. The results obtained are presented in Table 1 and are expressed on an air-dry weight basis equivalent to 87 ± 1 per cent dry matter. The figures in the table refer to the material dis-

Table 1. DISTRIBUTION OF RIBOFLAVIN IN *Triticum vulgare* VAR. THATCHER

	Proportion of grain by wt. (per cent)	Riboflavin in fraction (μgm./gm.)	Riboflavin in grain (μgm./100 gm.)	Proportion of that in whole grain (per cent)
Whole grain	100	1·8	180	—
Pericarp + testa	8·2	—	—	—
Aleurone	6·7	10·0	67	37
Embryo	1·6	13·8	22	12
Scutellum	2·0	12·7	25	14
Endosperm	81·5	0·7	57	32
	100·0		171	95

Table 2. DISTRIBUTION OF PANTOTHENIC ACID IN *Triticum vulgare* VAR. THATCHER

	Proportion of grain by wt. (per cent)	Pantothenic acid in fraction (μgm./gm.)	Pantothenic acid in grain (μgm./100 gm.)	Proportion of that in whole grain (per cent)
Whole grain	100	7·8	780	—
Pericarp + testa	8·2	7·8	64	8
Aleurone	6·7	45·1	302	39
Embryo	1·6	17·1	27	3·5
Scutellum	2·0	14·1	28	4
Endosperm	81·5	3·9	318	41
	100·0		739	95·5

sected from a number of grains and not to the fractions of an individual grain. The pericarp + testa fraction contained very little riboflavin (less than 5 per cent), and accordingly no attempt was made to obtain the exact figure because of the tedium in dissecting the large amount required. The other figures are the means of duplicate determinations, and there is good agreement between the riboflavin content of the whole grain and the total of that in the various fractions.

Pantothenic acid. The results, again expressed on an air-dry weight basis and the means of duplicate assays, are given in Table 2. With this vitamin it was possible to obtain a figure for the pericarp + testa fraction on a relatively small amount.

In Table 3 the results obtained previously for aneurin[8] and nicotinic acid[9] have been summarized, together with the results reported above for riboflavin and pantothenic acid. The table shows clearly the differences in the pattern of the distribution of these four vitamins. Common to them all, however, is the relatively high concentration of each in the aleurone layer, nicotinic acid being, of course, outstanding: in fact, we believe the aleurone layer of cereals to be the richest natural source of this vitamin.

In wheat, the aleurone layer is derived from the endosperm tissue, which is generally accepted to result from the fusion of the polar nuclei with the second male gamete, the first gamete fertilizing the ovum to produce the embryo. This aleurone layer, which constitutes less than 7 per cent of the total weight of the grain, contains 31 per cent of the aneurin, 84 per cent of the nicotinic acid, 37 per cent of the riboflavin and 39 per cent of the pantothenic acid.

Other B-vitamins. Accurate information on the distribution of the remaining B-vitamins is not yet available. Table 4, however, shows the vitamin content of certain flours with respect to pyridoxin, folic acid, biotin and the four factors already discussed. These figures suggest that pyridoxin and folic acid are distributed in a similar manner to riboflavin, whereas the distribution of biotin may resemble either that of nicotinic acid or that of pantothenic acid. Furthermore, from the figures quoted by Pringle and Moran[10] for the phytin content of various milling fractions, it would appear that about 80 per cent of the total phytin is found in the bran, which is composed of the pericarp, testa and aleurone layers together with small amounts of endosperm. Hence, since most of the inositol (another member of the B-group of vitamins) in wheat is present in this form, that is, a mixed calcium and magnesium salt of inositol hexaphosphoric acid, it is probable that a high concentration of this vitamin also exists in the aleurone layer. Thus the conclusion is that all those members of the B-vitamin group upon which we have any data are present in high concentration in this layer.

Discussion. The various members of the B-vitamin complex are all thought to be coenzymes or to be involved in some way in specialized enzyme systems. Thus, aneurin is known to be involved in several enzymatic reactions connected with carbohydrate metabolism, the best known of which is probably the carboxylase reaction; riboflavin and nicotinic acid are known to enter into several mechanisms concerned with the transfer of hydrogen and thus respiration; pantothenic acid is concerned in acetylation reactions, while pyridoxin derivatives

Table 3. DISTRIBUTION OF CERTAIN B-VITAMINS IN THE WHEAT GRAIN

Fraction	Total in fraction as percentage of that in whole grain: Aneurin	Nicotinic acid	Riboflavin	Pantothenic acid	Concentration in each fraction in μgm./gm. Aneurin	Nicotinic acid	Riboflavin	Pantothenic acid
Pericarp + testa	1	4	~5	8	0·6	25·7	~1·0	7·8
Aleurone	31	84	37	39	16·5	741	10·0	45·1
Embryo	2	1	12	3·5	8·4	38·5	13·8	17·1
Scutellum	62·5	1	14	4	156	38·2	12·7	14·1
Endosperm	3	11·5	32	41	0·13	8·5	0·7	3·9

Table 4. THE B-VITAMIN CONTENT OF FLOUR
(All figures are expressed as μgm./gm. flour at 13 ± 1 per cent moisture)

Flour	Aneurin	Nicotinic acid	Riboflavin	Folic acid	Biotin	Pyridoxin	Pantothenic acid
1. Patent	0·54	8·7	0·55	0·10	0·011	3·3	1·0
2. White flour (77·4 per cent extraction)	1·79	14·9	0·70	0·13	0·020	3·8	1·9
3. National flour (80 per cent extraction)	2·31	17·0	0·69	0·13	0·025	4·0	2·3
4. 'Low-grade' flour rich in germ and bran	3·36	22·7	0·90	0·17	0·031	4·4	2·9
5. Wholemeal flour or whole grain	3·75	59·3	1·70	0·37	0·090	9·3	7·4

enter into several enzymic reactions concerned with amino-acid metabolism.

Although distribution studies have not been carried out upon the enzymatic reactions involving these co-factors, Engel and his co-workers[11] have studied the distribution of a number of enzymes in wheat, using techniques based upon serial sectioning of the grain. Their results show that amylase is found principally in the outer endosperm and scutellum but not in the aleurone layer or embryo; proteinase is found mainly in the aleurone layer and not in the endosperm, small amounts being found in the embryo and scutellum; dipeptidase and esterase activities are high in the scutellum, embryo and aleurone layer and low in the endosperm. A study of phytase[12], based upon the dissection techniques used in this communication, has also shown that the aleurone layer and the scutellum have the highest activities. Hence, with the enzymes so far studied, with the exception of amylase, their activity is high, if not greatest, in the aleurone layer. Another point of interest in connexion with the aleurone layer is that the ash content and thus the mineral content is higher than that of any other fraction of the wheat grain (unpublished observations by Hinton).

In seeds, the potential centre of metabolic activity is the embryo, and the high concentration of aneurin in the scutellum, which is a specialized part of the embryo, could be explained on this basis. It is another matter, however, to find the concentration of essential metabolites mentioned above in the aleurone layer, which is a tissue unrelated to the embryo. On the other hand, it is customary to regard the carbohydrate and protein found outside the embryo of a resting seed as deposits to be mobilized as required by the developing seedling. It might therefore be suggested that these 'deposits' of vitamins and enzymes in the aleurone layer could have the same role. Against this, however, it is known that excised cereal embryos will develop to maturity on a nutrient medium which does not contain any added source of vitamins or growth factors[4,13]. Though the growth of the plant is somewhat weak, development can proceed normally to maturity, as is shown in the accompanying photographs.

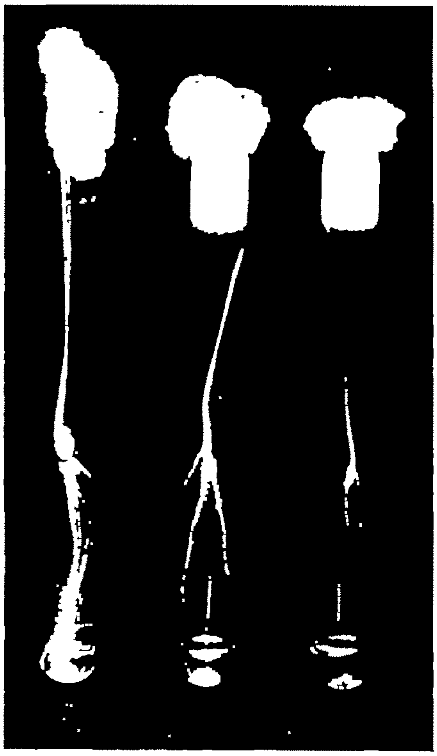

Fig. 1. Wheat plants in test-tube culture seven days after germination. Left, from whole seed; centre, from embryo plus scutellum; right, from embryo alone

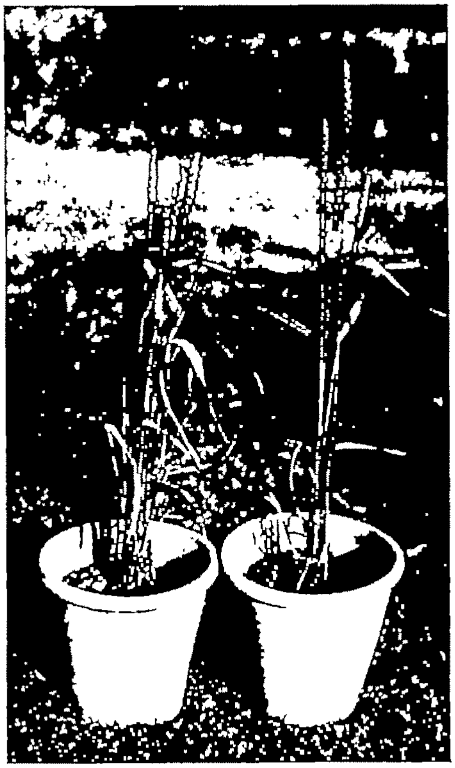

Fig. 2. Mature wheat plants (var. Atle) from excised embryos grown in 10-in. pots. Left, from embryo alone, right, from embryo with scutellum. The grain was under-weight, but normal and viable

The significance, therefore, of the high content of the B-vitamins and of minerals and the high enzymic activities in the aleurone layer still awaits explanation. Certainly they do not appear to play a decisive part in the metabolic processes of the developing embryo.

We are indebted to Mr. H. N. Ridyard for the aneurin estimations in Table 4. [Oct. 13.

Fine Structure of the Extra-terrestrial Radio Source Cygnus I

THE investigation of the nature of the intense localized sources of extra-terrestrial radio emission which were discovered in 1948 has been hampered by the technical difficulties of achieving sufficient resolution to measure their dimensions. Partial solutions of these difficulties were reached simultaneously in 1952 by independent developments at Cambridge, Jodrell Bank and Sydney[1-3], as a result of which preliminary measurements of the angular diameters of the intense sources in Cassiopeia and Cygnus were made. These measurements were not in complete agreement, particularly in the case of the Cygnus source, where the Jodrell Bank results indicated that the source might be markedly asymmetrical. During the past year the fine structure of this source has been studied in greater detail, and the present communication summarizes the results obtained.

The investigation has been made on a frequency of 125 Mc./s. with an interferometer which has been described elsewhere[1,4,5]. It measures the variation of the correlation function ρ^2 with the aerial separation in terms of wave-lengths (N), where

$$\rho^2 = \frac{F^2 \cos\psi + F^2 \sin\psi}{F^2 \cos(o)}$$

and $F \sin\psi$ and $F \cos\psi$ are the sine and cosine terms of the Fourier transform of the angular distribution of intensity across the source[4]. The original measurements made by Hanbury Brown, Jennison and Das Gupta[1] with this interferometer were carried out at position angles of 58°, 113°, 179°, and the results indicated that the source was radially asymmetrical with a major axis near position angle 90°. In order to obtain a self-consistent set of results with these earlier measurements in a direction close to the major axis, the present investigation has been made at a number of spacings in the position angle 113°. The correlation function and the corresponding values of N are given in the accompanying table.

The measurements of Smith[2] and Mills[3] were made in position angle 90°, and in order to compare the three sets of results the present observations have been transformed into a position angle of 90°. This has been done by projecting the values of N from position angle 113° to 90°, and the values are given in the table.

The intensity distribution shown in Fig. 1 compares these results with those of Smith and Mills. The magnitude of the secondary maximum indicates that the source must have at least two distinct centres of emission. The distribution of intensity across the source cannot be determined uniquely since the phase of the transform is unknown; however, the shape of the curve in Fig. 1 suggests that the phase of the transform is reversed in the secondary maximum, and this favours a symmetrical source with two centres of emission.

INTERFEROMETER SPACINGS N AND CORRESPONDING CORRELATION COEFFICIENT ρ^2 FROM THE EXTRA-TERRESTRIAL RADIO SOURCE CYGNUS 1

1,952	1,800	0·245
2,100	1,930	0·280
2,220	2,050	0·290

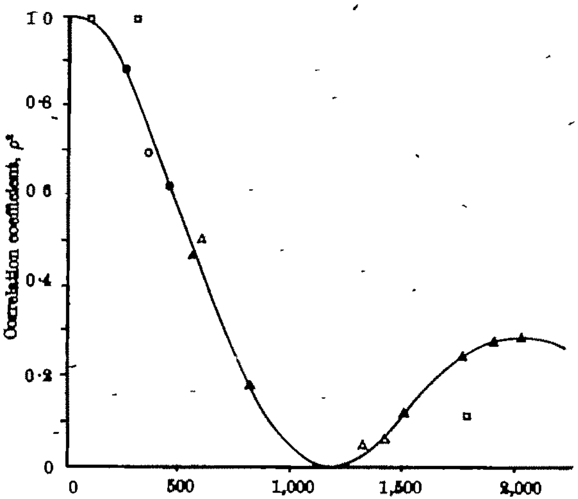

Fig. 1. Correlation coefficients ρ^2 measured at various interferometer spacings, N, for the radio source in Cygnus. Observations by Smith, ○; observations by Mills, □; observations by Jennison and Das Gupta, △. The continuous curve denotes the theoretical transform of the distribution shown in Fig. 2

The simplest distribution which will yield the transform shown in Fig. 1 consists of two components of equal intensity, each of length 51″, separated by 1′ 28″. The additional information[1] supplied by the results obtained on bearings of 179° and 58° indicates that the source has a very small minor axis—less than 35″ in a position angle of approximately 180°—and it is apparent that the components forming the source must be distributed in a narrow strip as shown in Fig. 2.

The accurate position of the radio source in Cygnus has been determined by Smith[6]. It coincides with an extra-galactic object photographed at the 200-in. Hale telescope by Baade and Minkowski[7]. This object has a maximum diameter of 30″ in position angle 150° and shows a high excitation emission spectrum with marked signs of tidal distortion. It has been interpreted by Baade and Minkowski as two late-type spiral galaxies in collision. Although Fig. 2 represents the most compact distribution of

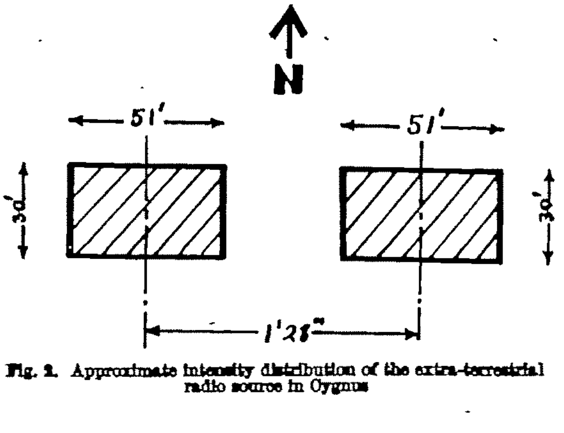

Fig. 2. Approximate intensity distribution of the extra-terrestrial radio source in Cygnus

the radio source which can be derived from the measurements shown in Fig. 1, it is nevertheless much larger than the visual object described above. The two components of the radio source straddle the visual object with little overlap between the regions of optical and radio emission. If this identification of the radio source is correct, there would appear to be no direct correlation between the radio emission and the visible light from the colliding galaxies.

The work was made possible by a grant from the Department of Scientific and Industrial Research. We wish to thank Prof. A. C. B. Lovell and Mr. R. Hanbury Brown for their interest in the investigation. We are also indebted to Drs. Baade and Minkowski for the information about their work on the colliding galaxies in advance of publication. One of us (M. K. D. G.) is indebted to the Government of India for a scholarship and to the Department of Scientific and Industrial Research for a maintenance grant, and the other (R. C. J.) to the Royal Society for the Mackinnon studentship.

An Extended Radio-frequency Source of Extra-galactic Origin

THE detection of the radio-frequency radiation from the Galaxy[1] together with that from a number of individual nebulæ[2-5] (types *Sb* or *Sc*) suggests that the emission of radio energy is a common property of the spiral nebulæ. It is therefore to be expected that the marked irregularities which are observed in the distribution of extra-galactic nebulæ (see Fig. 1) will give rise to corresponding irregularities in the radio isophotes of the sky. In a previous publication[5] we reported the detection at 158·5 Mc./s. of an extended band of low-intensity radiation, lying between declinations N. 44° and N. 54° and centred at R.A. 12h., and we suggested that the irregularity is associated with a concentration of nebulæ.

Since the publication of these preliminary results, the observations of the band have been extended to cover the declination range N. 40° to N. 70°, which represents the limit of the field of view of the aerial system (the 218-ft. paraboloid of the Jodrell Bank Experimental Station). The boundaries of the band observed over this region are given by the heavy lines in Fig. 1, and a comparison with the distribution of bright nebulæ indicates that the band is associated with the dense strip of nebulæ which extends over a wide range of declination and lies between R.A. 11h. and R.A. 13h. This identification has recently received support from some observations of Kraus and Ko[6], who have measured the radiation at 250 Mc./s. from that part of the band of nebulæ which lies between N. 15° and S. 15°. The broken lines in Fig. 1 show the loci of maximum intensity in the band of radiation which they reported. They noted that the band is about 15° wide and is bifurcated above the celestial equator.

The intensity of the band observed at 158·5 Mc./s. is about 3×10^{-24} W./sq. m./c.p.s./sq. degree, while the intensity of the band at 250 Mc./s. is given as 1×10^{-23} W./sq. m./c.p.s./sq. degree at a declination of S. 5°. The spectrum of the radiation from the band has been estimated from some observations made at 72 Mc./s. and 158·5 Mc./s. with the 218-ft. paraboloid, and the intensity appears to vary inversely as the square root of the frequency. Assuming this spectrum, the intensity observed at S. 5° corresponds to an intensity at 158·5 Mc./s. of $1·5 \times 10^{-23}$ W./sq. m./c.p.s./sq. degree, which is greater by a factor of 5 than that observed between declinations N. 40° to N. 70°. This increase of intensity towards the Virgo region is to be expected from the distribution of the bright nebulæ, and the factor of 5 is in reasonable agreement with the plot of nebular density given by de Vaucouleurs[7].

A comparison has been made of the observed radio intensity with that to be expected if all nebulæ show the same ratio of radio flux to light flux as that found for individual spirals[8]. The analysis is based on a detailed survey made by Shapley and Jones[9], which gives the counts of nebulæ on a series of photographic plates taken in a strip 5 degrees wide and centred on declination N. 43°. When estimating the total light flux from the nebulæ in this strip, it was assumed that they obey Holmberg's luminosity function, and a correction was applied to the counts for nebulæ below the plate limits. An additional small correction was applied to the integrated light flux to allow for the absorption of visual radiation by interstellar matter in nebulæ viewed edge-on. It was found that the observed radio flux is more intense

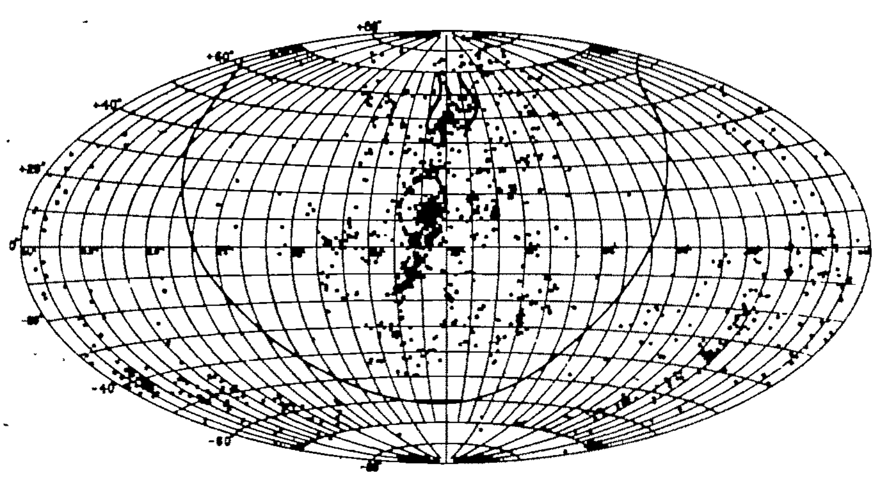

Fig. 1. Distribution of extra-galactic nebulæ brighter than the 13th photographic magnitude as given by Shapley and Ames. The heavy full lines show the boundaries of the band of radio-frequency radiation observed at 158·5 Mc./s. The broken line represents the loci of the points of maximum intensity of the band observed by Kraus and Ko at 250 Mc./s.

by about 1·7 magnitudes than that calculated. Part of this discrepancy may be caused by failure of the photographic observations to measure the light from the outer regions of the faint nebulæ, but it seems unlikely that the correction for this effect can reduce the discrepancy to less than 1 magnitude. This result may indicate that the ratio of radio to light flux for late-type spirals does not hold for all types of nebulæ.

The work has been carried out at the Jodrell Bank Experimental Station of the University of Manchester. We wish to thank Prof. A. C. B. Lovell for his interest in the investigation. One of us (R. H. B.) is indebted to Imperial Chemical Industries, Ltd., for a research fellowship.

Thermal Decomposition of Dolomite

In 1951, Wilsdorf and Haul[1] estimated from X-ray powder diagrams the size of the magnesium oxide crystallites formed when dolomite is heated to 600°–640° C. to be 10^{-5} to 10^{-4} cm. in diameter, and presumed that the crystallites were located on the periphery of the recrystallized calcite. In this work a pure dolomite crystal from Binnental, Switzerland, was used.

During the course of a joint study of dolomites, two showing distinct differences in their thermograms—from Steetley, Co. Durham, and from Loch Kishorn, Ross and Cromarty (Fig. 1)—were selected for further investigation, and powdered samples of these were heated in the differential thermal analysis apparatus[2] to the temperature corresponding to the junction between the two peaks. X-ray examination at this point revealed the presence of only magnesium oxide and calcium carbonate.

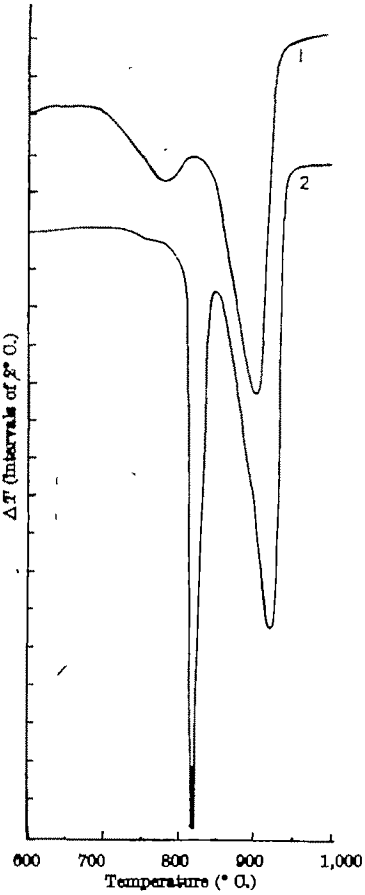

Fig. 1. Differential thermogram of (1) Steetley dolomite, (2) Loch Kishorn dolomite

Electron micrographs made by one of us (R. M.) at the Rheinisch-Westphälisches Institut für Übermikroskopie show large crystals covered with small crystallites. In the pictures of Steetley dolomite (Fig. 2), the commonest sizes of the crystallites are 1–4 × 10^{-5} cm. in diameter; but the total range is 1–6 × 10^{-5} cm., agreeing closely with X-ray evidence on a different material. That the crystallites in the Loch Kishorn dolomite appear to be smaller (mainly 1 and 2 × 10^{-5} cm. in diameter) is perhaps not surprising as the difference in rate of decomposition of the two samples (Fig. 1) would suggest that the magnesium oxide crystals from Steetley would have relatively more time to grow. In both preparations a small proportion of the crystallite material is seen apart from the larger crystals.

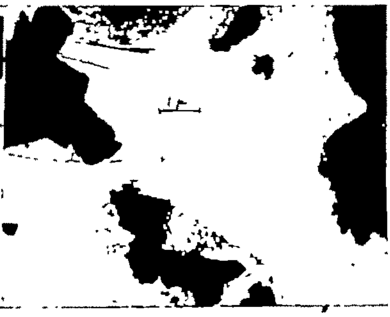

Fig. 3. Half-burnt Loch Kishorn dolomite after long heating and hydration

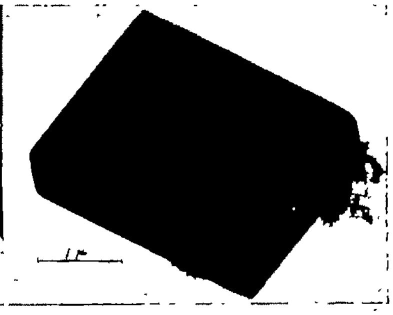

Fig. 4. Half-burnt Loch Kishorn dolomite after long heating and treatment with ammonia solution

When the dolomites were heated to 1,000° C., X-ray examination showed them to consist only of magnesium oxide and calcium oxide; the crystallites of magnesium oxide have now grown to about twice the size, and rather larger quantities have parted from the mother crystals, which are now pseudomorphs after calcite. One can also see that the crystallites nearest the decomposed calcite are often spherical or botryoidal in shape and that those farther away are usually unevenly grown octahedra.

Great care was taken to keep these samples dry; but one set of samples, after heating to 800° C. for a short time and then at 750° C. for 2 hr., was allowed to pick up atmospheric moisture (Fig. 3). In this case the magnesium oxide crystallites had been almost entirely replaced by an envelope of magnesium hydroxide enclosing the calcite crystals. In some of the clearest pictures, these hulls are seen to consist of an open network of minute needles.

When the half-burnt preparations from the last experiment were dispersed in a large volume of $N/100$ ammonium hydroxide solution (probably containing ammonium carbonate) the magnesium hydroxide crystallites dissolved and the remaining calcite (Fig. 4) is seen to have a perfect rhombic habit. Although the photograph shows a large single crystal about 3×10^{-3} cm. in length (with a little magnesium hydroxide still adhering), the calcite occurs mainly as aggregates of rhombs, about $0{\cdot}5$–1×10^{-3} cm. in length. Half-burnt dolomites from the differential thermal analysis apparatus, on the other hand, had been in the temperature-range 700°–800° C. for only 10 min., and in this time the calcite crystals, extracted with the ammonium hydroxide solution, are much less perfectly crystallized.

Electron micrographs of finely ground dolomite showed no perfect rhombs and few good cleavage planes. The present work confirms, therefore, that calcite crystallizes as the magnesium oxide leaves the dolomite lattice and becomes more perfect in crystal habit on continued heating.

We acknowledge the interest shown and help given by Dr. R. C. Mackenzie and Mr. W. A. Mitchell, of the Department of Pedology, Macaulay Institute for Soil Research, Aberdeen.

Creep Curve for a Precipitation-hardened Alloy

In recent years, there has been much interest[1–3] in the nature of creep curves obtained when metals are deformed at constant stress and temperature. Most of the experiments in this field refer to pure metals, but there has been some theoretical and experimental work[6,7] on the interesting subject of a precipitation-hardened alloy.

Some experiments have been performed here on creep deformation in a polycrystalline precipitation-hardened alloy, which show novel features depending mainly on the temperature of deformation. A binary alloy was used of composition 97 per cent copper–3 per cent silver, which was heat-treated to give a Widmanstätten structure of maximum hardness and stability. Wires of this alloy were subjected to small axial creep strains at constant stresses and temperatures.

Two distinct transient creep mechanisms and a quasi-viscous creep mechanism were observed. The first transient creep mechanism occurs at the lower temperatures (100° C. and 150° C.) according to the equation:

$$\epsilon = \alpha \ln t,$$

where ϵ is the creep strain at time t. This equation is typical of the exhaustion theory of transient creep[5,6] and is accounted for by a discussion put forward by Smith[3]. At higher temperatures (200° C. and 250° C.), the second transient creep term which obeys Andrade's law[1] is dominant over the first, and an additional quasi-viscous term is present:

$$\epsilon = \alpha \ln t + \beta t^{1/3} + \gamma t.$$

A similar relationship in regard to α- and β-transient creep has been found in pure metals by Wyatt[4].

At the highest temperatures used (275° C. and 300° C.), α-creep is negligible and the γ term is valid only up to a critical time (t_c) beyond which it is reduced exponentially with time:[7]

$$t < t_c \quad \epsilon = \beta t^{1/3} + \gamma t$$

$$t > t_c \quad \epsilon = \beta t^{1/3} + \gamma t_c + a\gamma \{1 - \exp -(t - t_0)/a\}.$$

The critical time effect is believed to be due to the comparatively large instantaneous plastic strain (P) on initial stressing, giving rise to a disordered structure at crystal boundaries, and allowing a limited boundary creep strain (γt_c) before further strain hardening. This view is supported by the constancy of the ratio $\gamma t_c/P$. It is hoped to publish full details of this work elsewhere.

I am indebted to Mr. J. V. Hardwick for discussions on the above work and to Mr. L. J. Davies, director of research, The British Thomson-Houston Co., Ltd., for permission to publish this communication.

Structure of Ion-exchanged Forms of Chabazite

The structure proposed by Wyart[1] for chabazite includes only the case for the divalent calcium ions, in the positions ± (0·17, 0·17, 0·17). In the case of a chabazite containing monovalent ions, these must also be placed on the triad axis if the symmetry D_{3d}^{5} is to be maintained without the formation of a 'defect structure'. Barrer[2] has shown that ion-exchanged forms of chabazite rich in the alkali metal cations, among others, give X-ray powder photographs showing negligible alterations in spacings when compared

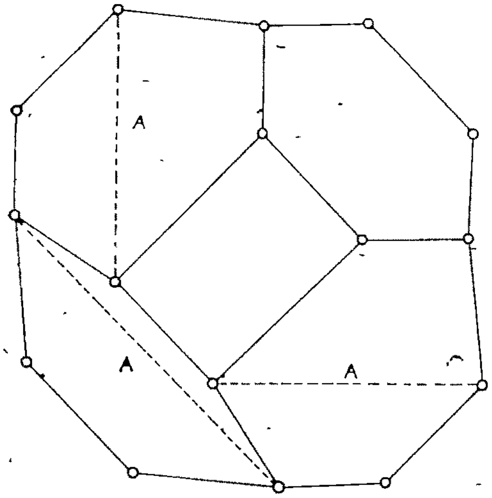

Fig. 1. Projection of the four six-membered rings of aluminiums and silicons in the upper half of the unit cell of chabazite

with the parent mineral. This indicates that the alumino-silicate network is essentially the same for all the cations, from lithium to cæsium. Initially, it would appear suitable to place these ions at the points (0, 0, 0), (0·5, 0·5, 0·5) and ± (0·25, 0·25, 0·25). However, these four positions are not all equivalent to one another, and, further, the situation of a cation at (0·5, 0·5, 0·5), for example, where it is in the centre of a cage which is otherwise devoid of atoms, is unlikely.

A further alternative, also mentioned by Wyart as a possibility for the calcium form, is that the ions occupy the positions (0·25, 0·25, 0·75), giving, as he states, six equivalent positions. This would result in a 'defect structure', similar to that of analcite as originally proposed by Taylor[3], with either two divalent or four monovalent ions in a statistical distribution between six of the lattice points.

Fig. 1 is a projection of the four six-membered silicon and aluminium rings found in the upper half of the unit cell of chabazite. The centres of three of these approximately planar rings represent half the six crystallographically equivalent positions (0·25, 0·25, 0·75) denoted by *A*. The dotted line in each of the *A* rings indicates the position of the widest portion of the hexagon formed (7·4 A.), the other distances being smaller and equal (6·2 A.). Each silicon or aluminium takes part in four rings of the type shown, so that on the average each contains four silicons and two aluminiums. A little consideration will show that it is impossible to place silicons and aluminiums in these rings so that the positions *A* are equivalent while the ratio of silicon to aluminium remains at two to one. Therefore, it follows that two only of these positions can be energetically equivalent, due to the presence of both aluminium and silicon atoms, although all three are crystallographically equivalent.

From the above discussion, it is apparent that the four monovalent ions in the unit cell of chabazite may be in four of the six positions given by (0·25, 0·25, 0·75) without the resultant lattice necessarily having the characteristics of a 'defect structure'. There is not room to accommodate the larger cations exactly in these sites, with the result that some slight displacement of these ions to fresh equilibrium positions will occur.

It is possible to apply similar reasoning to the case of a chabazite containing only divalent ions, since a position of minimum potential energy for a monovalent ion is not necessarily representative of the potential energy-well for a divalent ion. In complex structures of this type, it is probable that cation–cation coulombic repulsion forces are of great importance in determining the equilibrium position. Incidentally, it would appear that there is an error in "Strukturbericht"[4], where the positions of the silicon–aluminium atoms in chabazite are shown with $Z_{Si} = -0{\cdot}14$. This should read $Z_{Si} = -0{\cdot}01$.

Small-Angle X-Ray Scattering and Interparticle Interference in Rayons

THE scattering of X-rays at small angles by fibres furnishes important information about their microcrystalline structure. In a systematic study of this type of X-ray scattering by fibres[1], it was found that in the swollen condition these materials exhibit a more intense scattering over a much wider angle than in the dry state; this has been confirmed by others[2,3]. The effect was explained by the denser packing of the scattering particles (microcrystallites) in the dry state, and the greater extent of interference of the scattered radiation from neighbouring particles to be expected in this condition, as compared to the swollen condition where the particles scatter more independently.

An investigation of the scattering by fibres in stages between the dry and highly swollen condition proved of interest for obtaining a deeper insight into the phenomenon of interparticle interference in these materials and with regard to the experimental conditions ensuring a reliable determination of microcrystallite size in fibres.

The material reported on in this preliminary note are two rayons of high orientation: 'Fortisan' (courtesy of the Celanese Corporation of America) and 'Fiber G' (courtesy of the du Pont de Nemours Company). Highly monochromatized K_{α} radiation and a beam of high quality obtained with two combined quartz crystals was used for the investigation. The distance between sample and film was 20 cm.

Fig. 1, *A* and *B* are full-size reproductions showing the scattering by these fibres, *A* in the dry condition, *B* in the water-swollen condition, *C* swollen beyond the water-swollen condition. The exposure in *A*, *B* and *C* is the same and the same fibre sample was used in each case. The proportions of average diameter of fibres in *A*, *B* and *C* are about 3½–4½ to 5–5½ to 6. The swelling beyond the water-swollen state is still of a purely intermicellar nature. The exact distribution of intensity is given by the curves of Fig. 2.

From the patterns and curves it is seen that the scattering of the fibre in the dry condition, *A*, is limited to a narrow angular distance from the centre, whereas the swollen fibres, *B* and *C*, show a wider distribution of intensity. In the water-swollen condition, *B*, the intensity passes through a maximum and minimum. This has also been observed but not explained by others[3]. Maxima or inflexion points are found in almost any condition between the most compact (driest) and fully swollen states; some examples are given by the curves *B*, *B′* in Fig. 2. If the fibre is swollen beyond the water-swollen condition as represented by *C*, a distinct maximum is no longer observed. A slight inflexion is still seen in the curve *C* for 'Fortisan'; but even this is no longer present in curve *D* in Fig. 2 (for 'Fiber *G*'). The overall intensity in cases *C* and *D* is very much higher than in any of the other cases notwithstanding the higher absorption of X-rays by the highly swollen material.

The above finding that the extent and shape of the inflexion in the scattering curves varies with the degree of swelling can be fully explained on the basis of interparticle interference in the denser states of packing. The presence of a minimum, maximum or inflexion point at lower degrees of swelling can be predicted mathematically on this basis. At a sufficiently high degree of swelling, the particles will scatter independently and the 'single-particle curve' is obtained. This is in agreement with the complete disappearance of the inflexion as observed with 'Fiber *G*' in the highest swollen condition.

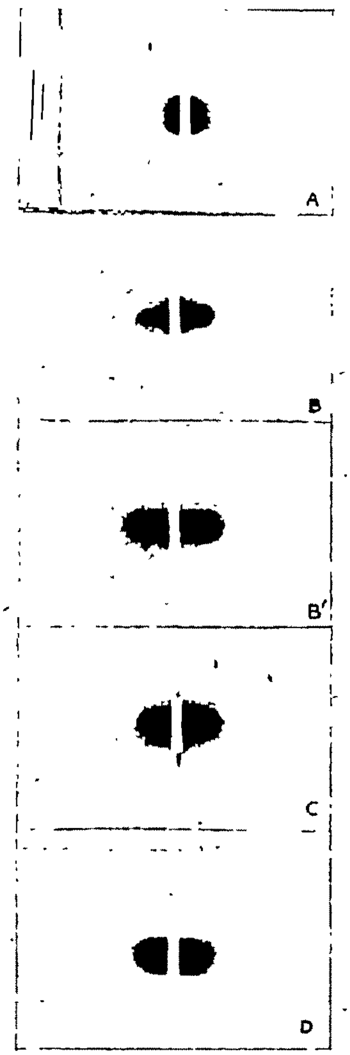

Fig. 1. Small-angle X-ray scattering by 'Fortisan' and 'Fiber *G*'. (*A*) 'Fortisan' in the dry state. (*B*) 'Fortisan' swollen in water. (*B′*) The same. (*C*) 'Fortisan' swollen beyond the water-swollen state. (*D*) 'Fiber *G*' swollen beyond the water-swollen state. Note limited scattering area in *A*; larger area and presence of a maximum in *B* and *B′*, and high intensity and absence of a maximum in *C*. Original size; sample to film distance, 20 cm.

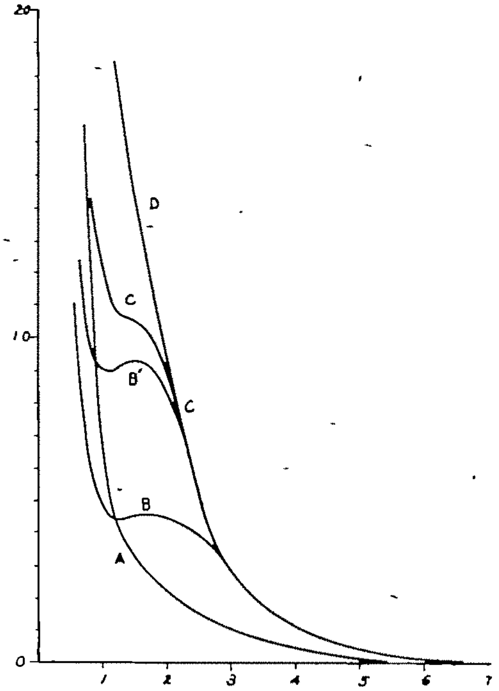

Fig. 2. Distribution of intensity in small-angle scattering by 'Fortisan' and 'Fiber *G*'. Abscissa: angle in 1/100 radians; ordinate; density, which is linearly proportional to intensity. (*A*) 'Fortisan' in dry state. (*B*) 'Fortisan' in water-swollen state. (*C*) 'Fortisan' swollen beyond the water-swollen state. (*D*) 'Fiber *G*' swollen beyond the water-swollen condition; the curve does not show any inflexion point. The curves obtained in other conditions of swelling with 'Fiber *G*' are very similar to those obtained with 'Fortisan' (*A*, *B*, *C*)

From the 'single particle curve' it is possible to determine the size of the scattering particles by plotting the logarithm of the intensity against the square of the scattering angle (see ref. 1, 1950 *b*). If a straight line is obtained, the particle size can be calculated from the slope of this curve. From scattering curves of type *D*, straight-line logarithmic curves were actually obtained, from which a particle size of 45·9 A. was calculated for 'Fortisan' and of 40·6 A. for 'Fiber *G*'. (The value for particle size refers to the diameter of the elongated cylinder supposed to constitute the microcrystallite. If the particle is not cylindrical, the value is a measure of the radius of gyration of the particle around its long axis.) If rayons are investigated under unsuitable experimental conditions (for example, curves of type *A* and *B*) straight-line logarithmic curves are not obtained.

A full account of the above experiments and of small-angle X-ray scattering by rayons in general will be published elsewhere.

Use of Non-geometrical Perspective in the Two-dimensional Representation of Solid Objects

If a scene be photographed with a camera the lens of which is at a distance D from the negative, it is generally agreed that a print from the developed negative, viewed from the same distance D, may be held up in front of the original scene so that it will then be observed to provide a representation of the original which is 'correct' in perspective. If the print be a transparency and viewed with one eye, points on the original may be seen to be covered exactly by corresponding points on the photographic image.

Such prints are described as giving 'correct perspective' when viewed from the distance D. By photographic 'enlargement' or 'reduction', print dimensions corresponding to multiples (or fractions) of D may be had from the same negative. This is, of course, the usual practice in modern photographic work. For example, prints held in the hand and viewed from a distance of 10–12 in. may thus be obtained in 'correct' perspective, even though the distance D in the camera was much less than this amount.

It is, however, noteworthy that if tests be made away from the original scene with a number of prints of differing degrees of enlargement, the print selected as presenting the most lifelike representation of the original will be not that which gives 'correct perspective' under the particular conditions of viewing, but one which would require to be viewed at a greater distance if 'correct perspective' conditions were to be obtained. This fact is widely exploited by professional photographers, theories of geometrical perspective notwithstanding.

Consideration of an address by Dr. R. H. Thouless[1] provides an explanation of this anomaly. The following quotation, removed from its context, may be inserted here. "If an object is moved to twice its previous distance from our eyes, it does not look half its previous size. It may, for different individuals, look three-quarters of its previous size or nineteen-twentieths. With rare exceptions . . . the apparent size is in between the retinal size and the real size." Hence a two-dimensional print, viewed from a fixed distance, will appear more like the original scene of finite depth when the diminution of scale of reproduction with distance is less than correct geometrical perspective would dictate. This is provided in practice by the use of a print which is viewed at a distance which is less than that necessary for 'correct perspective'. The optimum ratio of enlargement will differ for various individuals; but in theory at least, the ratio could be chosen to give a print which was most generally acceptable as providing an appearance of correct perspective, that is, appearing 'lifelike', under given viewing conditions. These observations should be qualified by certain limitations mentioned in Thouless's address (*loc. cit.*, p. 207).

Similar considerations may provide one reason for the lack of artistic success of art students who attempt drawings of solid objects as if they were exercises in geometrical perspective, measuring up the scene on a pencil held at arm's length.

So far, neither artists nor photographers have been able to explain in terms acceptable to the scientist why representations in correct geometrical perspective are not those most acceptable to the eye, even where they have clearly understood this fact. It would appear, however, that the key to the statement and discussion of the phenomenon in scientific terms has been available for some time.

I am much indebted to Dr. V. R. Pickles for his advice in this matter.

Pozzolanic Activity of Ash produced by the Eruption of Mt. Lamington, New Guinea

On January 21, 1951, Mt. Lamington, New Guinea, commenced a series of violently explosive eruptions during which large quantities of steam and ash were ejected. Further explosions occurred on January 27–28 and on February 19, 1951, after which volcanic activity slowly subsided.

Such accumulations of volcanic ashes can be of interest because they may constitute suitable sources of a pozzolanic material. Lea[1] has defined pozzolanas as "siliceous materials which, though not cementitious in themselves, contain constituents which, at ordinary temperatures, will combine with lime in the presence of water to form compounds which have low solubility and possess cementing properties". In recent years much interest has been aroused in the use of pozzolanic materials in mass concrete work. Such materials, blended in suitable proportions with portland cement, not only increase the supply of available cement at very low cost, but also are regarded as improving the durability of concrete.

Samples of Mt. Lamington ash, which were obtained by the Bureau of Mineral Resources, were subjected to examination and to a number of tests to determine their pozzolanic activity. The ash, which had the chemical composition of an andesite, consisted largely of particles that passed through a No. 18 and were held on a No. 150 B.S. sieve. Tests, according to the procedure of Mielenz *et al.*[2], showed that the samples of ash reacted readily with sodium hydroxide solution and that silica was dissolved. These observations indicated that the ash should act as a pozzolana and that fine-grinding, which enhances reactivity, would be necessary for the satisfactory preparation of the pozzolana.

Flexural strength tests were made on small-scale ($\frac{1}{2}$ in. × $\frac{1}{2}$ in. × 4 in.) mortar specimens and, after rupture, the ends of the specimens were tested in compression. The technique of making the specimens, their storage and details of the testing procedure will be described elsewhere. The mortars consisted of a pozzolanic cement and quartz sand (-25 to $+52$ B.S. mesh) mixed in the ratio 1 : 1 by weight. The pozzolanic cement consisted of mixtures of pozzolana (ground to -300 B.S. mesh) and hydrated lime in the ratio of 2 : 1 by weight. For control purposes lime alone was used in some specimens as the cementing material. The modulus of rupture and compressive strength at ages up to twenty-eight days of the different mortars are given in the table. The material used in pozzolanic mortar A was taken from the lower ash layer, that in mortar B was from the upper layer.

These results indicate that Mt. Lamington ash possesses pozzolanic properties and that it could be used, at least locally, for blending with portland

Type of mortar	Water : cement ratio	Strength at various ages (days) after fabrication					
		Modulus of rupture (lb./sq. in.)			Compressive (lb./sq. in.)		
		7	14	28	7	14	28
Pozzolana *A*	0·24	433	499	546	3,850	4,100	5,350
Pozzolana *B*	0·24	276	342	508	2,250	3,100	4,450
Lime	0·23	92	83	101	770	730	1,000

cement. The results also suggest that other similar volcanic deposits may be potentially valuable. Further work on the behaviour of blended portland–pozzolana cements is in progress and will be reported elsewhere.

We are indebted to Dr. H. G. Raggatt, former director, to Dr. N. H. Fisher, chief geologist, to Mr. A. H. Debnam and to other officers of the Bureau of Mineral Resources for securing the samples of ash from Mt. Lamington and for chemical analyses.

Amino-Acids and the Growth of Isolated Oat Embryos

THERE have been numerous reports of interactions between amino-acids in their effects on the growth of bacteria and fungi, while relatively few interactions of this type have been reported in studies with higher plants. Mixtures of amino-acids have been found to interact in their effects on the growth of immature *Datura* embryos[1]. Antagonisms have been reported between canavanine and structurally related amino-acids in their effects on the growth of *Avena* coleoptile sections[2] and immature embryos of maize[3]. Experiments reported here extend these observations in so far as they expose a series of interactions between amino-acids in their effects on the growth of mature embryos of oat. These interactions have been observed as antagonisms between individual amino-acids in their effects on root growth.

Embryos of oat (var. Victory) were grown in sterile culture in the dark at a temperature of 25 ± 1° C. Each embryo was grown in a separate culture vessel, in which it was supported at the surface of 50 ml. of liquid medium. The basal medium, to which the amino-acids under test were added, contained: (1) inorganic salts as used by Burstrom[4] for the culture of excised roots of wheat but with potassium chloride and calcium chloride substituted for the corresponding nitrates and with ferric sulphate omitted; (2) organic growth factors as used by White[5] for the culture of excised roots but with glycine omitted; (3) 0·2 *M* sucrose. The initial *p*H of all media was adjusted to a value of 6·2 ± 0·2 by the addition of suitable quantities of 0·01 *N* sodium hydroxide. The media were sterilized by autoclaving at a pressure of 15 lb. for five minutes.

It was found that the total linear growth of the embryos could be substantially increased by the addition of a vitamin-free casein hydrolysate to the basal medium. The effect of the hydrolysate could be simulated by supplying a synthetic mixture of eighteen amino-acids in its place. The effect of twelve of these amino-acids was studied by supplying them alone and in pairs, at the same concentrations as those used in the mixture. The table shows the effects of the amino-acids supplied alone (Exp. 1) and in combination with phenylalanine (Exp. 2) and with valine (Exp. 3) on the growth in length of the roots. When supplied alone, eleven out of the twelve amino-acids were inhibitory to root growth, while one, arginine, had little effect. In the majority of cases where amino-acids were supplied in pairs, the pair proved to be less inhibitory to root growth than was the most inhibitory of its constituent amino-acids supplied alone. In certain instances interactions were very marked. Phenylalanine was particularly effective as an antagonist for tyrosine and also showed marked interactions with serine and with threonine. Valine, which was the most inhibitory of the amino-acids when supplied alone, was effective in relieving the inhibition of growth produced by leucine and by isoleucine. These two interactions involving valine were striking in that the growth value obtained with the combination of acids exceeded that obtained with either alone.

THE EFFECT OF AMINO-ACIDS SUPPLIED ALONE AND IN COMBINATION WITH PHENYLALANINE AND WITH VALINE ON THE LENGTH OF THE ROOTS OF ISOLATED OAT EMBRYOS MEASURED AT THE END OF A SEVEN-DAY CULTURE PERIOD. ALL VALUES ARE BASED ON THE MEANS OF MEASUREMENTS MADE ON AT LEAST TEN SEEDLINGS

Amino-acid	Conc. mgm./l.	Length of roots as percentage of control (basal medium) in each experiment		
		Exp. 1. No addition	Exp. 2. Addition of L-phenylalanine, 17·5 mgm./l.	Exp. 3. Addition of DL-valine, 35·2 mgm./l.
None	—	100	70	14
L-Arginine	17·5	106	86	23
L-Phenylalanine	17·5	72	—	22
L-Aspartic acid	26·3	66	79	20
L-Glutamic acid	87·6	64	58	20
L-Proline	35·2	47	62	28
L-Lysine 2HCl	30·4	39	33	18
DL-Threonine	17·5	30	59	25
L-Leucine	21·9	29	37	41
DL-Isoleucine	21·9	28	42	44
L-Tyrosine	26·3	27	64	23
DL-Serine	26·3	21	45	17
DL-Valine	35·2	15	22	—
Length of roots in basal medium (control) in mm.		317	308	304

The results of further experiments have confirmed the existence of a marked interaction between DL-valine and DL-isoleucine and have indicated that no similar interaction occurs between DL-isoleucine and L-leucine. Evidence has also been obtained for interactions between glycine and DL-serine and between L-arginine and L-lysine.

I wish to express sincere thanks to Dr. H. E. Street, under whose direction this work was carried out in the Department of Botany, University of Manchester.

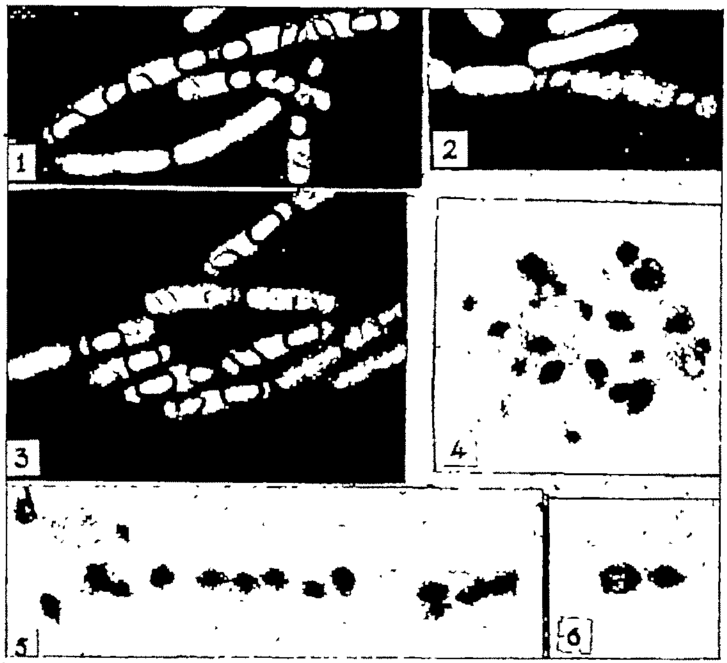
Crystalline Inclusions in Aerobic Spore-forming Bacteria

B. thuringiensis Berliner[1] is an aerobic spore-forming bacillus, classified by Smith, Gordon and Clark[2] as *Bacillus cereus* var. *thuringiensis*, because apart from its pathogenicity for certain insects and the tendency of the spores to lie obliquely in the cell, the organism is indistinguishable from *B. cereus*.



(1) *B thuringiensis.* Air-mounted nigrosin film. Unstained. Robinow's technique (ref. 5). × 2,400
(2) Crystal-bearing cell of *B. thuringiensis* in which the spores have lysed before reaching maturity. × 2,400
(3) Crystals and spores in Bacillus No. 1. A constituent of 'Sporeine' powder which is pathogenic for *Ephestia kuhniella* Zell. Jacobs (ref. 6). × 2,400
(4) Free crystals and spores of *B. thuringiensis.* Hydrolysed at room temperature in $N/3$ nitric acid containing 0·1 per cent potassium permanganate (Method 2, Robinow, ref. 7). Stained with crystal violet and photographed mounted in water. × 2,400
(5) Crystals alternating with spores in a chain of *B. thuringiensis.* Hydrolysed in hydrochloric acid at 60° C. for 15 min. and stained with crystal violet. Photographed mounted in water. × 2,400
(6) Crystal attached to free spore. Stained with crystal violet and photographed mounted in water. × 3,600

During a study of spore formation in this organism, it was noted that the spores were invariably accompanied by what appeared to be diamond-shaped crystals (Fig. 1). Each cell contained only one crystal, and the order in a chain of cells was random. The crystals vary a great deal in size (Fig. 4) but are always the same shape, and are set free with the spores and persist indefinitely. Occasionally a crystal may be firmly attached to a spore (Fig. 6). Lysis may occur in the early stages of spore formation so that a cell may contain a crystal but no spore (Fig. 2).

Cultures of spore-forming insect pathogens (variants of *B. cereus*) from other sources have been examined and it has been found that the majority form crystals on sporulation (Fig. 3). All strains of *B. cereus* that were obtained from other sources and which were not known to be pathogenic for insects, together with strains isolated from soil and foodstuffs, failed to form crystals on sporulation.

The crystals stain readily with Giemsa but more intensely with basic fuchsin and crystal violet, and most cleanly with Victoria blue. With the acid dye ponceau de xylidine dissolved in $N/10$ hydrochloric acid they stain a pale orange-red. After hydrolysis in N hydrochloric acid at 60° for 15 min. or in $N/3$ nitric acid with 0·1 per cent potassium permanganate, the crystals both free and within the cells are unaltered in size and shape and take up the stain more easily than before hydrolysis (Figs. 4 and 5).

The crystals are readily soluble in dilute alkali but are insoluble in water, physiological saline, ethanol, methanol, chloroform, ether, benzene and acetone. When dilute alkali is run under an air-dried coverslip preparation of crystals and spores, the crystals, while still retaining their shape, greatly increase in size, then lose their refractility and finally disappear, leaving behind a thin shell or membrane.

A biological phenomenon in which crystalline inclusions have only been found in strains of bacteria pathogenic for insects must inevitably, in the absence of additional observations, lead to some speculation as to the possible association of inclusions with pathogenicity. The crystals have certain features in common with the nuclear polyhedral crystalline inclusion bodies as elucidated by Bergold[3]; but their ability to take up stains is similar to the cytoplasmic inclusion bodies of Smith and Xeros[4]. They differ, however, in that so far as has been observed, only one crystal is formed in each cell. At the moment nothing is known about their composition, whether they contain a virus or phage, or whether the crystal formation is a genetical characteristic of the organism which is in some way connected with the formation of a toxic substance encouraging septicæmia of the insect larvæ.

Acetylcholine in Blowflies

A STUDY of two species of blowfly, *Calliphora erythrocephala* and *Lucilia sericata*, has shown that a rapid synthesis of an acetylcholine-like substance can take place in extracts prepared from these insects. This synthesis, which occurs in the absence of additional substrate, may account for some of the high concentrations of acetylcholine which have been previously reported in insects[1–3].

Flies were immobilized by cooling at 0° C., weighed, and extracts prepared according to one of the following methods: (*A*) grinding in a Potter–Elvehjem homogenizer[4] with Ringer solution containing 0·001

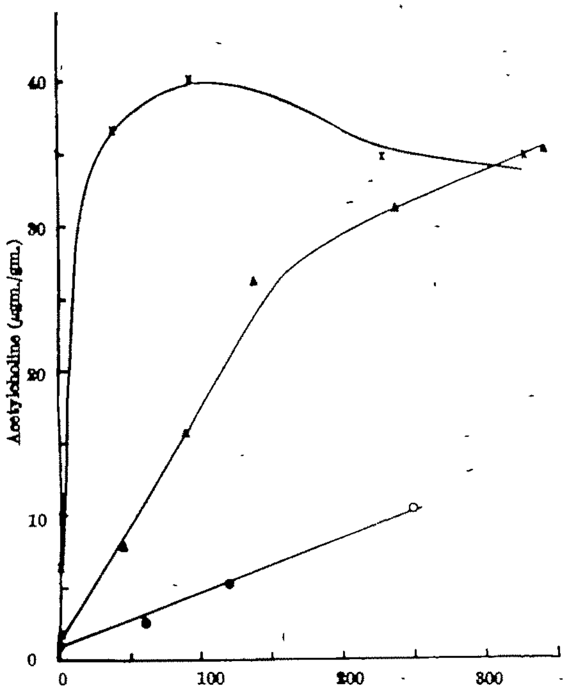

Fig. 1. Synthesis of acetylcholine in extracts from *Lucilia sericata*: ▲—▲—, whole insect; ×—×—, head (0·05 per cent eserine); ○—○—, thorax

per cent eserine sulphate and acidified with 0·33 *N* hydrochloric acid, followed by boiling as described by Feldberg[5]; (*B*) homogenizing with non-acidified Ringer solution containing either 0·001 or 0·05 per cent eserine sulphate, using 1 ml. Ringer/100 mgm. fly tissue. In each case the homogenate was centrifuged to remove chitin and tissue debris. The acetylcholine content was then assayed immediately or after incubation at 18° C., using the frog rectus abdominus muscle preparation, allowance being made for the presence of sensitizing substances in the extract as recommended by Feldberg[6]. Results obtained with extracts prepared according to method *A* are given in Table 1.

When tissue extracts were prepared by method *B*, the acetylcholine content was much greater, and increased rapidly on incubation (Fig. 1). In a sample taken 45 min. after homogenizing and boiled for 1 min., the acetylcholine content remained constant at 7·5 μgm./gm., while in the incubated extract it increased to 35 μgm./gm. in 350 min.

Supporting evidence for the identity of the substance synthesized in the fly extracts has been obtained by chromatographic analysis. An incubated extract was deproteinized with 10 per cent trichloracetic acid, and the supernatant extracted with ether and concentrated *in vacuo* at 40° C. The concentrate was extracted with ethanol and the extract again concentrated *in vacuo*. Two equal portions were taken and 15 μgm. acetylcholine added to one of them. Both portions were then run on Whatman No. 4 paper using the *n*-propanol/formic acid/water mixture described by Whittaker and Wijesundera[7]. The chromatogram was cut into ten sections, and each section eluted with 10 ml. Ringer solution and the eluates then assayed on the muscle preparation. The results showed no detectable separation of the active material in the extract from the acetylcholine added.

Table 1. ACETYLCHOLINE CONTENT OF EXTRACTS FROM FLIES
(μgm./gm. tissue, fresh weight)

Head	6·4	6·3
Thorax	—	1·0
Abdomen	—	<0·25

Table 2. ACETYLCHOLINE IN EXTRACTS FROM FLIES TREATED WITH DDT
(μgm./gm. tissue, fresh weight)

Incubation time (min.)	Untreated insects	Insects treated with DDT (time after treatment)	
		1 hr.	4·5 hr.
35	—	16	—
75	31	—	60
150	41	26	80

Tobias *et al.*[3] have shown that there is a considerable increase in the acetylcholine content of flies after poisoning with DDT. They found 47 μgm./gm. in normal flies (*Musca domestica*), whereas DDT-poisoned flies examined at the prostrate stage contained 131 μgm./gm. The methods used by these workers would not have excluded the possibility of synthesis occurring in the extract, and therefore this effect was re-investigated. Adult flies (*Calliphora erythrocephala*) were confined for 10 min. in a glass cylinder coated with DDT. Symptoms of poisoning developed rapidly and the insects were prostrate in about 4 hr. At this time the synthesis in extracts prepared from these flies by method *B* was found to be much greater than in extracts prepared from control flies. In extracts prepared from flies showing intense activity 1 hr. after treatment with DDT, the synthesis was less than in the controls. The results in Table 2 show the amounts synthesized in extracts prepared from heads and thoraces at 1 hr. and 4·5 hr. after DDT treatment.

These results suggest that the large increase in acetylcholine in flies poisoned with DDT and at the prostrate stage is due to an increased rate of synthesis in the extract which is not necessarily related to the acetylcholine content of the insect.

There is, however, a small increase in the biological activity of extracts prepared by method *A* from flies poisoned with DDT. The increase was equivalent to less than 0·5 μgm./gm. and could be demonstrated in flies only 20 min. after exposure to DDT; it is therefore not due to a rapid synthesis occurring during the preparation of the homogenate. This increase in biological activity has also been demonstrated in flies which were killed by immersion in liquid nitrogen 20 min. after treatment with DDT. In this case the frozen insects were homogenized in 10 per cent trichloracetic acid and the extract assayed after removal of the acid with ether. The nature of the substance remains to be investigated.

This work was carried out while on leave from the Pest Infestation Laboratory, Slough, and I wish to thank Dr. T. Mann for his advice and interest.

Detection of Fœtal and Sickle-cell Hæmoglobins in Human Anæmias

We have systematically examined a large number (175) of normal and anæmic bloods for the presence of fœtal hæmoglobin (F-Hb)[1] by three methods: (*a*) the position of the tryptophan fine-structure band[2], using the moving-plate method of Holiday[3], from which the relative proportions of adult (A-Hb)[1] and fœtal hæmoglobin can be estimated[4] when more than 10 per cent of the latter is present, though smaller proportions cannot be detected; (*b*) the Rich 'slope' method[5], using the Unicam *SP*.500 spectrophotometer, which has the same order of sensitivity; (*c*) the rate of alkaline denaturation at *p*H 12·8, which provides a sensitive means of detecting the more alkaline-resistant fœtal hæmoglobin[6].

A photoelectric colorimeter is used for measuring the rate of increase of absorbance (optical density) at 640 mμ due to the formation of alkaline hæmatin, and the observations are treated as a first-order process. Normal adult hæmoglobin shows a single component with half-reaction time ($t_{\frac{1}{2}}$) at 20° of 11·3 sec. (S.D. 2·3), whereas at birth cord-blood contains 70–80 per cent of fœtal hæmoglobin with $t_{\frac{1}{2}}$ of the order of 10^3 sec. As little as 2 per cent of fœtal hæmoglobin can be detected by 'tailing' of the main slope, and when more than 7 per cent is present, a good estimate of the fœtal component can be obtained by extrapolation.

The presence of sickle-cell hæmoglobin (S-Hb)[1] is readily determined by measurement of the solubility of the reduced hæmoglobin in *p*H 6·7 phosphate buffer at ionic strengths (Γ/2) between 3·84 and 5·45[7]. Regression lines differing in height on the (log) solubility axis but not in slope have been obtained for the solubility of normal adult hæmoglobin and for the mixed hæmoglobins from sickle trait and sickle-cell anæmia erythrocytes. At Γ/2 = 4·75, the mean solubilities for hæmoglobins from the three groups were 6·38, 2·00 and 0·66 gm./litre respectively. (The greater proportion of sickle-cell hæmoglobin in sickle-cell anæmia erythrocytes, as compared with sickle trait erythrocytes, is presumably the explanation for the higher birefringence of the former after reduction.)

The three methods for detection of fœtal hæmoglobin are very reliable when used in conjunction. The 70–80 per cent of fœtal hæmoglobin present at birth is rapidly replaced by adult hæmoglobin during the first four months of life. Blood from cases of acute leukæmias, erythro-leukæmia, myelosclerosis, paroxysmal nocturnal hæmoglobinuria, aplastic, hypochromic and megaloblastic anæmias, and from a target-cell anæmia in liver disease, has been examined; also from a wide variety of familial hæmolytic anæmias associated with spherocytosis or ovalocytosis, or in various atypical forms[8]. The great majority has contained only adult hæmoglobin, or not more than a trace of fœtal hæmoglobin (less than 3 per cent, and this detectable by the alkaline denaturation method only). However, in one child of three years with acute paramyeloblastic leukæmia, 10–20 per cent of fœtal hæmoglobin was present.

In Mediterranean and sickle-cell anæmias fœtal hæmoglobin may be encountered more frequently[8,9,10]. We have found 12–20 per cent of fœtal hæmoglobin in the erythrocytes of a Cypriot child of three years; this child's parents' cells, and those of two other Mediterranean traits, contained only the adult form. In sickle-cell anæmia, we have encountered 20 per cent of fœtal hæmoglobin persisting in a child of one year, but none in a further five cases in adults or in sixteen cases with the sickle trait. Both parents of individuals with anæmia of sickle-cell type do not always carry the sickle trait, but one may carry the Mediterranean or some other trait[10]. In our work, erythrocytes from three affected offspring from three such families were found to contain 20 per cent, 3 per cent and no fœtal hæmoglobin.

It appears that the presence of fœtal hæmoglobin after infancy is associated with the hereditary Mediterranean, sickle-cell and related diseases. In other hereditary hæmolytic conditions, and in severe blood dyscrasias, even those with extra-medullary hæmopoiesis, the hæmoglobin is most usually of the normal adult type.

We are grateful to many colleagues for blood samples. A fuller account will appear elsewhere.

Prevention and Cure of Enzootic Muscular Dystrophy in Beef Cattle

INVESTIGATIONS carried out in collaboration with the veterinary investigation officers in Scotland have shown that a muscular dystrophy of suckling beef calves is quite commonplace. In Inverness and adjoining counties it appears that the disease occurs on some 15–25 per cent of all farms rearing beef cattle, and that the incidence on these farms may occasionally approach 90 per cent. Studies of the gross and microscopic pathology have shown the disease to be very closely comparable to both experimental vitamin E deficiency[1] and the cod-liver oil toxicity syndrome[2,3] of calves. Furthermore, analyses of the feeding-stuffs making up the winter rations of the cows in these areas indicate that the intake of α-tocopherol is very low[4]. The disease almost invariably occurs in calves born indoors in spring to mothers which have been housed since the previous autumn.

Experiments, which have now been carried out on twenty 'susceptible' farms in the vicinity of Inverness, show that vitamin E will prevent the disease. On each farm half the cows were given α-tocopheryl acetate before parturition, and the remainder were

INCIDENCE OF DYSTROPHY IN GROUPS OF 42 CALVES ON 20 FARMS

	Dam received no tocopherol before calving		Dam received tocopherol before calving	
	Calf not treated	Calf given tocopherol	Calf not treated	Calf given tocopherol
Total No. of cases	11	3*	2	0
Deaths	3	0	0	0
Slight involvement only	3	3	2	0

* Dystrophy was diagnosed before the third day of life, that is, prior to treatment of the calf with tocopherol. It receded when tocopherol was given.

not treated. The calves born to these two groups were again subdivided, half receiving α-tocopheryl acetate and half none. The incidence of dystrophy, including deaths due to cardiac failure associated with degeneration of the myocardium, is summarized in the accompanying table.

No cases were observed in the group in which both dam and calf received tocopherol; but an incidence of more than 25 per cent occurred in the groups which received none at any time. In calves which died, dystrophic lesions were found and the creatine content of the muscles was depressed. When diagnosis was unequivocal, treatment of the calves was instituted, with complete recovery in all cases. Further field observations have also shown treatment, if commenced in the early stages, to be completely effective.

Studies of blood tocopherol concentration have shown that on farms where the disease is severe the concentration of tocopherols in the serum was less than 40 μgm./100 ml., which is considerably below the normal value of more than 150 μgm./100 ml. found in normal healthy calves in Ayrshire.

Full details of these experiments will be published elsewhere. We are indebted to Roche Products, Ltd., for gifts of some of the tocopherol used in these studies and to our colleagues for their assistance.

Linkage between Pulmonary Tumours and Vestigial Tail in the House Mouse

THE occurrence of pulmonary tumours in the mouse has been shown to be controlled by multiple genetic and non-genetic factors, the tumours appearing when the combined effect of these factors surpasses a physiological threshold[1]. Tests for linkage[2,3] have demonstrated association between the occurrence of pulmonary tumours and the genes, lethal yellow (A^y), flexed tail (*f*), hairless (*hr*), and the linked genes shaker-2 (*sh*-2) and waved-2 (*wa*-2). There was evidence that the relationship to A^y was due to the positive effect of the gene itself upon susceptibility to this type of tumour. Whether or not the relationship to the other genes represented true linkage was not ascertained; but certain evidence suggested secondary effects.

Recently, tests have been made for linkage between pulmonary tumours and vestigial tail (*vt*), a new recessive mutation that arose in this laboratory[4]. During this time, Michie[5] has located *vt* in linkage group VII within a few units of *sh*-2 and about 19 units from rex (*Re*). This would place *vt* about 35 units from *wa*-2, which is on the other side of *sh*-2 from *Re*. Results reported herein indicated an association between occurrence of pulmonary tumours and *vt*, and are in line with Michie's evidence of close linkage between *vt* and *sh*-2 and with the preceding demonstration of association between pulmonary tumours and *sh*-2.

This test utilized backcross mice produced by mating three strain *A* females to the vestigial-tailed male and backcrossing the F_1 males and females to vestigial. In strain *A* mice eighteen months of age, the incidence of pulmonary tumours is 90 per cent, which is the highest incidence reported for any strain. Following the intravenous injection of 0·5 mgm. of 1 : 2 : 5 : 6 dibenzanthracene, pulmonary tumours occur in all mice of this strain at six weeks of age, and at sixteen weeks there is an average of 75 tumours in the lungs of each. The vestigial-tailed mice were of a stock developed through vestigial × vestigial matings of hybrids of the original analysis of the trait[4].

Two hundred and two of the backcross animals divided approximately equally between + *vt* and *vt vt*, and as to sex, were tested for degree of susceptibility to pulmonary tumour development by injecting each intravenously at two months of age with 0·5 mgm. of 1 : 2 : 5 : 6 dibenzanthracene dispersed in 0·5 c.c. horse serum. At eight months of age, each animal was killed and the number of tumours appearing on the pleural surface was recorded. The number of tumours has proved to be a sensitive quantitative measure of degree of susceptibility used in demonstrating differences due to genes or other biological factors and also chemical factors. As shown in Table 1, the normal tailed (+ *vt*) segregants were more susceptible to pulmonary tumours than were the vestigial-tailed (*vt vt*) segregants. The mean number of tumours in the two groups of + *vt* males combined was 10·5, whereas that for the two groups of *vt vt* males combined was 4·0. The difference between these means is highly significant; $t = 4 \cdot 26$; $P < 0 \cdot 01$. The mean number in the two groups of + *vt* females combined was 16·0 and that for the two groups of *vt vt* females combined was 8·96; the

Table 1. OCCURRENCE OF PULMONARY TUMOURS IN THE SEGREGATED BACKCROSS HYBRIDS

Genotype and sex	Sex of F_1 parent	Total mice	Mice with given No. of tumours				Mean No. of tumours
			0	1–10	11–20	21 +	
Vt vt ♂	♂	35	2	16	8	9	12·8
Vt vt ♂	♀	15	2	13	0	0	4·7
vt vt ♂	♂	45	8	31	5	1	4·6
vt vt ♂	♀	11	5	5	0	0	1·1
Vt vt ♀	♂	38	0	14	10	14	17·5
Vt vt ♀	♀	8	0	6	1	1	8·1
vt vt ♀	♂	40	3	23	10	4	9·8
vt vt ♀	♀	11	1	8	1	1	5·0

difference between these means is likewise highly significant; $t = 3 \cdot 31$; $P < 0 \cdot 01$. Thus, an association between susceptibility to induced pulmonary tumours and *vt* is clearly established.

In former tests it had been suggested that the decrease in both spontaneous and induced pulmonary tumours associated with *sh*-2 and *wa*-2 was due to *sh*-2 itself. No difference in occurrence of pulmonary tumours had been noted when *wa*-2 had been tested in the absence of *sh*-2. Furthermore, there was a positive correlation between increased body-weight and increased occurrence of pulmonary tumours, and certain genes, including *sh*-2, and other factors affecting body-weight were shown to be associated with a similar effect upon occurrence of pulmonary tumours. Contrary to this former suggestion, true linkage is now indicated. In the present tests *sh*-2 was not involved and, furthermore, *vt vt* did not reduce body-weight more than could have been expected from the absence of most of the tail. This would indicate a gene (or genes) influencing susceptibility located in linkage group VII at a locus near enough to *sh*-2 and *vt* to result in a difference in backcross segregants, but possibly so far from *wa*-2 that its effect was not detected in the test involving *wa*-2 alone. It is possible, however, that in the test of *wa*-2 alone the parental stocks were alike in respect to this susceptibility gene or these genes.

In the backcross hybrids of this test there was a sex difference in susceptibility to induced pulmonary tumours in that the females had on the average more tumours than the males. The mean number of tumours in all + *vt* females was 16·0, as compared with a mean number of 10·5 in all + *vt* males. The difference between these means is highly significant; $t = 2 \cdot 38$; P is between 0·01 and 0·02. Furthermore, the mean number of tumours in all *vt vt* females was 9·0 and that in all *vt vt* males was 4·0; the difference between these two means is also highly significant; $t = 3 \cdot 91$; $P < 0 \cdot 01$. In many former tests of strain *A* mice and their hybrid derivatives, sex differences have not been observed, whereas in certain groups of mice of other strains and hybrids of various types, sex differences have been observed; but in these cases the males have been more susceptible than the females[6].

In the present backcross segregants it was also noted that more tumours occurred in mice from matings of F_1 males × *vt vt* females than in those from F_1 females × *vt vt* males. This is of doubtful significance, however, inasmuch as there may have been genetic variation in the *vt vt* mice in respect to pulmonary tumours which could account for more tumours in progeny of F_1 males, especially since only two F_1 males were used in the backcross matings.

Transphosphorylation between Nucleoside Polyphosphates

DURING an investigation of the mechanism of phosphorylation of glucose by nucleoside triphosphates we have observed the transfer of the terminal phosphate group of adenosine triphosphate to inosine diphosphate. The reaction can be formulated as follows:

$$\text{ATP} + \text{IDP} \rightleftharpoons \text{ADP} + \text{ITP}. \qquad (1)$$

This reaction is catalysed by an enzyme present in baker's and brewer's yeast and in extracts of rabbit muscle. It has been directly demonstrated in the following manner: adenosine triphosphate equally labelled in both labile phosphate groups with phosphorus-32 was incubated with inosine diphosphate and a dialysed protein fraction from brewer's yeast. The appearance of radioactivity in the inosine polyphosphate fraction was determined after separating it from adenosine di- and tri-phosphate by paper ionophoresis at pH 3·5 in $M/50$ citrate buffer. The results of a typical experiment are shown in Table 1. Also included is an experiment in which inosine triphosphate was the labelled substrate.

Table 1. TRANSFER OF PHOSPHATE FROM NUCLEOSIDE TRIPHOSPHATE TO NUCLEOSIDE DIPHOSPHATE

Exp. No.	Labelled substrate	Time (min.)	Radioactivity (counts/min.)		Percentage transfer of P
			ATP + ADP	ITP + IDP	
A	ATP	0	13,300	116	—
		5	12,500	930	6·9
		10	12,300	1,210	9·0
		20	9,700	1,740	15·0
		60	10,200	2,760	21·2
		120	9,400	2,640	21·4
B	ITP	0	810	5,580	—
		20	1,920	4,770	28·3
		40	2,140	4,550	32·0
		160	1,970	4,800	29·1

The reaction mixture for experiment *A* contained: $M/10$ *tris*-hydroxymethyl aminomethane buffer, pH 8; $M/60$ magnesium chloride; $M/150$ phosphorus-32-labelled adenosine triphosphate; $M/150$ inosine diphosphate; 1 mgm. yeast protein fraction; total volume, 1·0 ml. For experiment *B*: $M/10$ *tris*-hydroxymethyl aminomethane buffer pH 8; $M/60$ magnesium chloride; $M/500$ phosphorus-32-labelled inosine triphosphate; $M/500$ adenosine diphosphate, 0·5 mgm. yeast protein fraction; total volume, 1·0 ml.

It can be seen that reaction (1) could result from the transfer of an amino group as well as of a phosphate group. To distinguish between these two possibilities, each of the four components was isolated after an experiment similar to *A* in Table 1. The fractions containing adenosine and inosine were first separated as described above and then subjected to paper ionophoresis at pH 4·7 in order to separate the di- and tri-phosphates. The results obtained, together with the values predicted for either type of mechanism, are presented in Table 2. It is clear from the results that the reaction is a transphosphorylation.

The reversibility of reaction (1) is demonstrated by the ability of inosine triphosphate to phosphorylate adenosine diphosphate (experiment *B*, Table 1). In experiment *A* the reaction proceeds until the amount of radioactive phosphate incorporated into the inosine polyphosphate fraction approaches a quarter of that originally present in both labile phosphate groups of adenosine triphosphate. The reaction in the opposite direction (experiment *B*) approaches a similar limiting value. Since in both cases the initial nucleoside triphosphate was labelled equally in both labile phosphates, and the newly formed triphosphate contained only one labelled

Table 2. DETERMINATION OF THE SPECIFIC ACTIVITY OF THE COMPONENTS OF THE REACTION
(Figures represent counts per min./micromole)

Compound isolated	Theoretical for Transamination	Theoretical for Transphosphorylation	Formed
ATP	1,920	1,920	1,920
IDP	0	0	0
ADP	0	960	1,045
ITP	1,920	960	930

The reaction mixture contained *M*/10 *tris*-hydroxymethyl aminomethane buffer *p*H 8; *M*/50 magnesium chloride; *M*/150 phosphorus-32-labelled adenosine triphosphate; *M*/150 inosine diphosphate; 0·25 mgm. yeast protein fraction; total volume, 0·65 ml.

phosphate (Table 2), the equilibrium constant of the reaction is approximately 1.

The reaction is specific for nucleoside triphosphates as donors and nucleoside diphosphates as acceptors. Nucleoside monophosphates do not participate in the reaction. We therefore propose the name 'nucleoside diphosphokinase' for the new enzyme.

The transphosphorylation reaction can also be demonstrated spectrophotometrically. In the presence of yeast hexokinase[1] and a preparation of glucose-6-phosphate dehydrogenase[2,3], which contains 'nucleoside diphosphokinase', the rate of phosphorylation of glucose by inosine triphosphate (as measured by reduction of triphosphopyridine nucleotide at 340 mμ [4]) is markedly increased by catalytic amounts of adenosine diphosphate and approaches the rate found with adenosine triphosphate. A similar effect is seen if the new nucleoside triphosphate, uridine triphosphate[5], is used as the phosphate donor. The results of an experiment with the latter are shown in Fig. 1. It is seen that, as in the case with inosine triphosphate, the rate of phosphorylation of glucose by uridine triphosphate alone is very slow. On the addition of adenosine diphosphate, however, there is an immediate rapid reaction. The increase in absorption at 340 mμ has been adapted for use as a quantitative measure of uridine triphosphate. We have assayed a synthetic preparation of uridine triphosphate, kindly furnished by Prof. A. R. Todd, and the value obtained was in agreement with the estimate derived from chromatographic analysis. This technique would thus seem to offer a rapid and sensitive assay for nucleoside triphosphates.

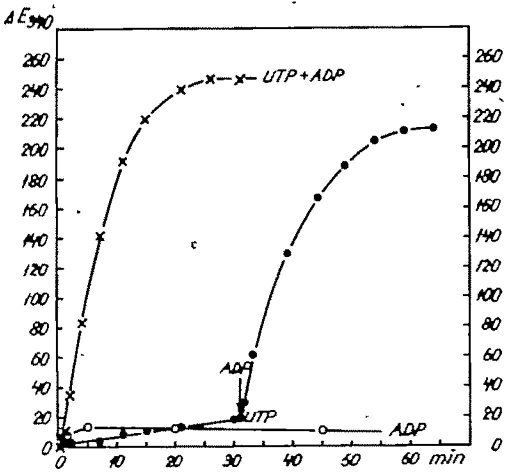

Fig. 1. Effect of adenosine diphosphate on the phosphorylation of glucose by uridine triphosphate.
Abscissa: time in minutes; ordinate: extinction × 10³ at 340 mμ.
The components of the reaction mixture were: *M*/10 *tris*-hydroxymethyl aminomethane buffer *p*H 8·2; *M*/100 magnesium chloride; *M*/50 glucose; *M*/5,000 triphosphopyridine nucleotide; *M*/20,000 adenosine diphosphate (added where indicated); *M*/20,000 uridine triphosphate (added where indicated); hexokinase, 'nucleoside diphosphokinase' and glucose-6-phosphate dehydrogenase as a yeast protein fraction 0·5 mgm.; total volume, 1·0 ml.

It appears likely that the previously reported formation of uridine diphosphoglucose from adenosine triphosphate and uridine diphosphate in the presence of glucose-1-phosphate[6] involved 'nucleoside diphosphokinase', since uridine triphosphate and glucose-1-phosphate react to form uridine diphosphoglucose[5].

It is also possible that the previously reported slow rate of glucose phosphorylation by uridine triphosphate[7] and inosine triphosphate[8] may be due entirely or in part to the contamination of these compounds by traces of adenosine diphosphate, since 'nucleoside diphosphokinase' occurs in the hexokinase and *Zwischenferment* preparations used to test these potential phosphate donors.

We would like to thank Dr. H. M. Kalckar for his encouragement and continued interest during this work.

Culture of *Fucus* Hybrids

IT has long been known that cross-fertilization could be carried out between any two of the three species of *Fucus*, *Fucus spiralis* L., *Fucus vesiculosus* L. and *Fucus serratus* L., and that sometimes quite a high percentage of hybrid zygotes would result[1–3]. There are no records, however, of the growth of hybrid sporelings in culture beyond the first few segmentations. There are also only very few satisfactory records of naturally occurring hybrids, though it might be assumed, since the cross can be made quite readily in culture, that it would also frequently occur in the sea.

We have recently[3] described two *Fucus* populations, one produced as the result of a clearance experiment on the shore at Port St. Mary, Isle of Man, and the other occurring naturally on the sandstone bank of the River Mersey at Eastham, Cheshire, populations which we believe to be hybrid swarms among the three *Fucus* species mentioned above.

Since fertilized eggs of hybrid origin are known to segment, and suspecting that hybrid populations occur naturally, it seemed at least possible that hybrids could be raised in culture. Attempts to raise such hybrids have been successful, and we have sporelings of *Fucus serratus* L., *Fucus vesiculosus* var. *evesiculosus* Cotton and the two reciprocal crosses between these two species growing in culture. The hybrids appear to develop as readily as the parent

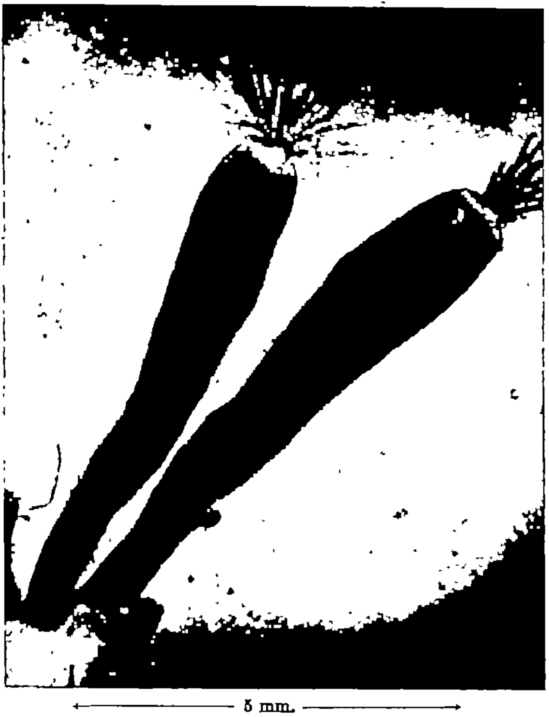

Fig. 1. Sporelings of *Fucus vesiculosus* var. *vesiculosus* ♀ × *F. serratus* ♂, 4 months old

species. All have reached a comparable stage and at four months old are 4–7 mm. in length. Although the majority are still in the cylindrical stage with well-developed apical hairs (Fig. 1), some have already flattened and are producing cryptostomata.

The sporelings have been raised on glass slides and small stones in glass vessels containing Erdschreiber culture solution in sea-water. The vessels are suspended in a constant-temperature culture tank kept at 10° C. and lighted from above by 'Daylight' fluorescent tubes for 18 hr. each day. No attempt has yet been made to imitate conditions of tidal exposure, and this has not appeared to be necessary.

We wish to thank Prof. N. A. Burges, in whose Department this work is being carried out.

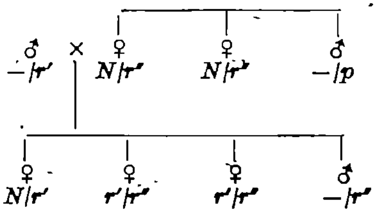
A Pedigree for Three Types of Colour-Vision Defect

The following pedigree is of interest because it shows three types of red-green colour vision defect together, namely, protanopia (*P*), extreme protanomaly (*EPA*) and protanomaly (*PA*) with darkened red, and because it supports the theory that *PA* is dominant to *EPA*[1,2].



The gene for *P* is represented as *p*, that for *EPA* as r'' and that for *PA* with darkened red as r'. *N* is the normal gene of the 'protan' series, and the gene for *PA* with red of normal brightness would be shown as *r* but does not appear in this pedigree.

The maternal uncle is a protanopic dichromat. He must have inherited his defect from his mother. The father is protanomalous with darkened red. The mother and her sister are presumably *EPA*-normal heterozygotes, their defective genes having come from their father. The first daughter is normal in colour vision and must be a *PA*-normal heterozygote. The second and third daughters are protanomalous and must be *PA–EPA* heterozygotes in which r' is dominant to r''. The son is an *EPA* subject and must be a hemizygote for the gene r''.

The second daughter is exactly like her father in colour vision, but the third daughter is slightly more defective, in the sense that she has a larger matching range but a smaller mean deviation. In order to account for this, it must be assumed that in her the gene r'' has more penetrance than in her sister, owing to unknown physiological differences, and that in her r' is incompletely dominant to it. The brother is much more defective, and includes the normal matching point in his matching range, but he is far from being a dichromat. All defectives in this pedigree failed the Ishihara test unequivocally and it did not distinguish them from each other.

Zoological Nomenclature

Notice is hereby given that the International Commission on Zoological Nomenclature has under consideration the following cases involving the possible use of its plenary powers for the purposes specified against each entry. Full particulars of these cases have been published in the *Bulletin of Zoological Nomenclature* in Double-Part 4/5 of Volume 9. (1) *Astacus* Fabricius, 1775 (Class Crustacea, Order Decapoda), validation of (correction of an error in *Opinion* 104); (2) *Favus* Lanchester, 1900 (Class Crustacea, Order Decapoda), validation of (correction of an error in *Opinion* 73); (3) *flavipes* Olivier, 1795, *Dytiscus* (Class Insecta, Order Coleoptera), validation of, by the suppression of *flavipes* Fabricius, 1792, *Dytiscus*.

Comments on the above cases should be sent as soon as possible to me.

Francis Hemming

Regent's Park, London, N.W.1.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, November 30

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Anniversary Meeting.

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (in the Lecture Room, Science Museum, South Kensington, London, S.W.7), at 5 30 p.m.—Dr. H. R. Calvert · "The Scientific Work and Inventions of Charles, 3rd Earl Stanhope".

Tuesday, December 1

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. R. A. Stirton (California): "Australian Mammalian Fauna and its Origin".*

ROYAL AERONAUTICAL SOCIETY (in the Library, 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. K. L. G. Legg: "Integral Construction".

Wednesday, December 2

BRITISH PSYCHOLOGICAL SOCIETY, INDUSTRIAL SECTION (in Room 106, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 1 p m.—Dr. R. Harper: "The Assessment of Foodstuffs".

INSTITUTE OF PETROLEUM (at 26 Portland Place, London, W.1), at 5.30 p.m.—Dr. F. P. Bowden, F.R.S.: "The Friction of Solids" (Redwood Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS, RADIO SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. T. Hayton, Mr. C. J. Hughes and Mr. R. L. Saunders: "Telegraph Codes and Code Convertors"; Mr. R. O. Carter and Mr. L. K. Wheeler: "Code Convertors for the Interconnection of Morse and Teleprinter Systems".

ASLIB, ECONOMICS GROUP (at The Goldsmiths' Hall, Foster Lane, London, E.C.2), at 6 p.m.—Mr. D. H. Lock: "Statistics: their Compilation"; Mr. W. Davies: "Statistics: their Use"; and Dr. H. Durant: "Statistics: their Application".

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at the Chemical Society, Burlington House, London, W 1), at 7 p.m. Prof. C. H. Gray: "Recent Advances in Medical Chemistry".

WOOL EDUCATION SOCIETY (in the Lecture Hall, Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7.30 p m.—Dr. Arthur Raistrick. "The Role of the Yorkshire Cistercian Monasteries in the History of the Wool Trade in England".

SOCIETY OF COSMETIC CHEMISTS OF GREAT BRITAIN (at the St. Ermin's Hotel, Caxton Street, London, S.W.1), at 7.45 p.m.—Dr. J. H. Schulman: "Molecular Interactions at the Solid-Liquid Interface with Special Reference to Emulsions Stabilized with Solid Particles".

Thursday, December 3

INSTITUTE OF LARYNGOLOGY AND OTOLOGY (at the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2), at 5.30 p.m.—Dr. Michael Ward: "The Ascent of Mount Everest: Medical Problems".*

INSTITUTE OF PHYSICS, LONDON AND HOME COUNTIES BRANCH (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. J. Topping. "The Use of Approximations in Physics".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5 30 p.m.—Mr. W. S. Procter, Mr. M. J. L. Pulling and Mr. F. Williams: "Technical Arrangements for the Sound and Television Broadcasts of the Coronation Ceremonies on June 2, 1953".

SOCIETY OF CHEMICAL INDUSTRY, MICROBIOLOGY GROUP (at the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W.1), at 6.15 p m.—Scientific Papers on "Dextran". (Speakers · Prof. M. Stacey, F.R.S., Mr. A. B. James, Dr. F. Fletcher, Mr. A. R. Lockwood and Mr. A. W Wilkinson.)

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

Friday, December 4

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. W. H. Bardgett and Dr. C. L. Clark: "Comparative High Temperature Properties of British and American Steels"; Dr. R. W. Bailey, F.R.S. "A Critical Examination of Procedures Used in Britain and the United States to Determine Creep Stresses for the Design of Power Plant for Long Life at High Temperatures".

BRITISH GLACIOLOGICAL SOCIETY (at the Scott Polar Research Institute, Cambridge), at 8.30 p.m.—Dr. W. S. Rogers and Dr. Irena Modlibowska: "Frost Damage to Plants".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. N. F. Mott, F.R.S.: "Dislocation, Fracture and Fatigue".

Saturday, December 5

ASSOCIATION OF AGRICULTURE, and BRITISH AGRICULTURAL HISTORY SOCIETY (at the Institute of Education, University of London, Malet Street, London, W.C 1), at 10.30 a.m.—Conference on "Studies in Regional History".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT, Grade B, IN MATHEMATICS, and an ASSISTANT, Grade A, IN MATHEMATICS AND SCIENCE, at Derby Technical College—The Principal, Derby Technical College, Normanton Road, Derby (December 5)

ASSISTANT, GRADE B (with good qualifications in physics, and preferably with teaching and/or industrial experience), IN THE DEPARTMENT OF PHYSICS AND MATHEMATICS—The Registrar, College of Technology, Suffolk Street, Birmingham 1 (December 5).

LECTURER (with good honours degree in chemistry, and research or industrial experience in physical or inorganic chemistry) IN CHEMISTRY—The Registrar, The Technical College, Sunderland, Co. Durham (December 5).

PHYSICAL CHEMIST (preferably with experience in the macromolecular field)—for a senior research post—The Director, Brewing Industry Research Association, Nutfield, Surrey (December 5).

SENIOR LECTURER (with honours degree, and preferably with industrial and teaching experience) IN THE DEPARTMENT OF CHEMISTRY—The Registrar, College of Technology, Suffolk Street, Birmingham 1 (December 5).

RESEARCH ASSISTANT (graduate in physics or mechanical science) IN PHYSICS, to carry out fundamental studies on stress waves in solids—The Registrar, University College of Wales, Aberystwyth (December 7).

SECRETARY (male, with university degree and experience of administration and editing, and preferably with a knowledge of science)—The Secretary, British Association, Burlington House, Piccadilly, London, W 1 (December 11).

CHEMIST and PHYSICIST (with at least H.S.C. (science) or equivalent, and preferably with experience in analytical chemistry, corrosion of metals, biochemistry, meteorology or physical testing, including optics), at the Ministry of Supply Tropical Testing Establishment, Port Harcourt, Nigeria, to assist in study of effects of tropical conditions on service materials and equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.591/53A (December 12).

MATHEMATICIANS (Scientific Officer, Assistant Experimental Officer and Experimental Officer grades) in Ministry of Supply Research and Development Establishments, mainly in the South of England, for work which includes research into aerodynamics and aircraft structures, high speed electronic computors, radio and radar, including aerial design and radiation problems, engineering problems, and trials work—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.117/53A (December 12).

SENIOR RESEARCH ASSISTANT (preferably of Ph D. standing, and with experience of X-ray techniques, including counters), and a RESEARCH ASSISTANT (with experience in vacuum or electronic techniques) IN THE ELECTRON MICROSCOPE SECTION of the Cavendish Laboratory, in connexion with the work which is being carried out on the X-ray microscope—The Secretary, Department of Physics, Cavendish Laboratory, Free School Lane, Cambridge (December 12).

FUEL TECHNOLOGIST (Coke Technical Officer) to be responsible for advising on all technical aspects of coke development—The Secretary, North Western Gas Board, Bridgewater House, 60 Whitworth Street, Manchester 1 (December 14).

CHAIR OF BACTERIOLOGY in the Faculty of Medicine—The Secretary, Queen's University, Belfast (December 15).

SENIOR LECTURER or LECTURER (Grade A) IN PHYSICS, and LECTURERS (Grade A or B) IN BOTANY, ZOOLOGY, CHEMISTRY and MATHEMATICS at the Kumasi College of Technology, Gold Coast—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (December 15).

ASSISTANT EXPERIMENTAL OFFICER (with a pass degree in botany or other suitable qualification) at the WELSH PLANT BREEDING STATION, for work in grass and clover breeding—The Registrar, University College of Wales, Aberystwyth (December 19).

CHAIR OF PHILOSOPHY—The Registrar, The University, Liverpool (December 19).

SCIENTISTS (with good honours degree, or equivalent in a science subject, and preferably with a sound background in geology and chemistry) IN THE COAL SURVEY LABORATORIES at Glasgow and Nottingham, for work which will include the preparation of detailed reports on the structure and physical and chemical properties of the coal seams covered by these laboratories—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/705 (December 19).

LECTURER IN AGRICULTURAL CHEMISTRY at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C 1 (December 31)

PLANT PATHOLOGISTS (graduates from a recognized university, with some postgraduate experience and training in plant pathology) in the Tobacco Research Board of Southern Rhodesia—The Director, Tobacco Research Board of Southern Rhodesia, P.O. Box 1900, Salisbury, Southern Rhodesia (December 31).

SCIENTIFIC ASSISTANT (with a degree in a biological science, and some knowledge of languages) IN THE COMMONWEALTH BUREAU OF ANIMAL HEALTH—The Director, Commonwealth Bureau of Animal Health, Veterinary Laboratory, New Haw, Weybridge, Surrey (January 1).

PROFESSOR OF PSYCHOLOGY at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 25).

AGRICULTURAL OFFICERS (with a degree in agriculture, and not less than two years postgraduate training or experience in agriculture) in the Colonial Territories (at present mainly in East and West Africa and Fiji)—The Director of Recruitment (Colonial Service), Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDR.63/01

ASSISTANT LECTURER IN AGRICULTURAL BOTANY (Plant Pathology)—The Bursar, Royal Agricultural College, Cirencester

Chemist (graduate or equivalent) for research on the drying of printing inks, with special reference to the influence of paper—Printing, Packaging and Allied Trades Research Association, Randalls Road, Leatherhead, Surrey.

Chemist (with first- or second-class honours degree with chemistry as the principal subject, or an equivalent qualification) with the Pyrethrum Board of Kenya, to take charge of chemical laboratories in Nakuru dealing with the analysis of pyrethrum flowers and with chemical investigations in connexion with the growing, preparation and marketing of the material—Box "CC/176", c/o 95 Bishopsgate, London, E.C.2.

Electrical Engineers (preferably graduates or corporate members of I.E.E. or I.M.E., and with sound training and appropriate experience) with the Central Electricity Board, Federation of Malaya—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M2C/28770/T.A.

Entomologist (experienced) with the Empire Cotton Growing Corporation, to take charge of research on cotton pests at their principal research station near Kampala, Uganda—The Secretary, Empire Cotton Growing Corporation, 12 Chantrey House, Eccleston Street, London, S.W.1.

Entomologists (2) in the Colonial Insecticides Research Unit, Tanganyika—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.87/8/01.

Experimental Officer or Assistant Experimental Officer at the National Physical Laboratory, Teddington, for work on design of research equipment and instruments—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.588/53A.

Experimental Officers (with at least H.S.C. (chemistry) or equivalent) (Ref. F.139/53A); and Assistants (Scientific) (Ref. F.140/53A) in the Chemical Inspectorate, Ministry of Supply, for analytical work on atomic energy materials in N.W. England, and for general analytical work in various localities in England and Wales—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King St., London, S.W.1, quoting appropriate Ref. No.

Lecturer or Assistant Lecturer in Animal Physiology—The Secretary and Registrar, The University, Southampton.

Mathematician (with good honours degree) at the British Rayon Research Association, to programme work to their electronic digital computer—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester.

Mechanical Engineers, Aerodynamicists, Physicists, Chemists, Metallurgists and Mathematicians in the Ministry of Supply, National Gas Turbine Establishment, near Farnborough, Hants—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.294/53A.

Physicist (with good honours degree) to assist in research into the fundamental principles underlying the processing of textile fibres into yarns—The Secretary, The British Jute Trade Research Association, Kinnoull Road, Kingsway West, Dundee, quoting Ref. N/1.

Physicists (with sound basic training, and prepared to apply their knowledge to problems from many fields including aerodynamics and aircraft structures, aircraft instruments, armaments, electronic circuits, radio and radar) at Ministry of Supply Research and Development Establishments, for duties mainly experimental, but may include trials work—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.170/53A.

Plant Physiologist (with good honours degree and postgraduate research experience) to direct and undertake fundamental biochemical investigations with a view to the ultimate development of mass culture technique for the lesser known marine algae of potential industrial value—The Secretary, Institute of Seaweed Research, Inveresk, Midlothian.

Principal Scientific Officers (2), (a) Mechanical and Electrical Engineer (with first- or second-class honours degree or equivalent qualifications, and preferably with a knowledge of metallurgy) (Ref. C.606/53A); (b) Physicist (with first- or second-class honours degree or equivalent qualifications, and preferably with industrial experience) (Ref. A.298/53A), at the National Physical Laboratory, Teddington, for scientific information services—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting appropriate Ref. No.

Research Chemist (with good honours degree in chemistry, preferably with Ph.D., or equivalent research experience) in the British Boot, Shoe and Allied Trades Research Association, to study effects of foot sweat on shoe leather and other related problems—The Director of Research, Satra House, Rockingham Road, Kettering, Northants.

Scientific Officer or Senior Scientific Officer (with first- or second-class honours degree or equivalent, and sound knowledge of properties and structure of metals and alloys) to investigate characteristics of radioactive alloy systems (Ref. A.295/53A); Experimental Officers or Assistant Experimental Officers (with at least H.S.C. (science) or equivalent) to work on (a) investigations on radioactive alloy systems, (b) determination of physical properties (for example, thermal expansion, electrical resistance, specific heat) of radioactive metals (Ref. A.296/53A), at the Atomic Energy Research Establishment, Harwell, Berks—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting appropriate Ref. No.

Scientific Officers (with first- or second-class honours degree in physics or electrical engineering or equivalent), and Assistant Experimental Officers (with H.S.C. (science) or equivalent) at the Ministry of Supply, London Headquarters, for research and development of electronic equipment, including guided weapons—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting D.446/53A.

Senior Biochemist (with appropriate university science degree or A.R.I.C., or equivalent qualification, and wide experience in biochemical work) at the Derbyshire Royal Infirmary, Derby—The Secretary, Derby No. 1 Hospital Management Committee, Babington Buildings, Babington Lane, Derby.

Technical Assistant (graduate in mathematical and/or physical science) in the School of Theoretical Physics—The Registrar, Dublin Institute for Advanced Studies, 64 Merrion Square, Dublin.

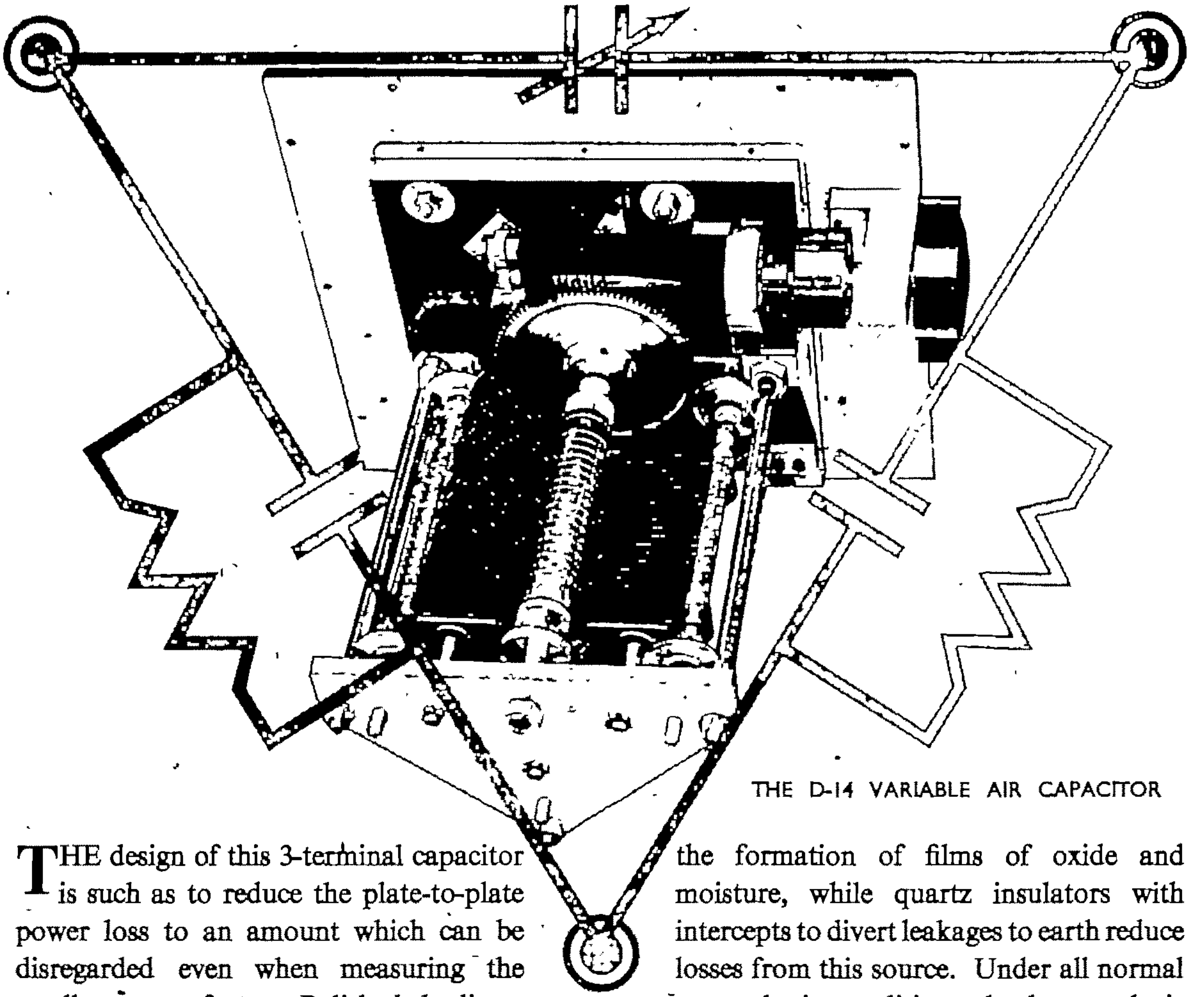
A CAPACITANCE STANDARD WITH ZERO LOSS

88



THE D-14 VARIABLE AIR CAPACITOR

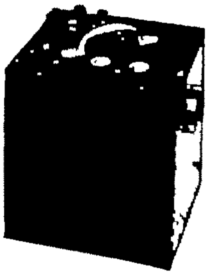
THE design of this 3-terminal capacitor is such as to reduce the plate-to-plate power loss to an amount which can be disregarded even when measuring the smallest power factors. Polished rhodium-plated brass vanes eliminate losses due to the formation of films of oxide and moisture, while quartz insulators with intercepts to divert leakages to earth reduce losses from this source. Under all normal atmospheric conditions the loss angle is less than 7 micro-radians.

SPECIFICATION

CAPACITANCE RANGE D-14A: 100$\mu\mu$F-1250$\mu\mu$F (calibrated); D-14-B: 100$\mu\mu$F-1000$\mu\mu$F (direct reading).

CALIBRATION ACCURACY D-14-A: ±0.3$\mu\mu$F; D-14-B: ±1$\mu\mu$F.

READING ACCURACY 1 part in 20,000 by interpolation.



LOSS ANGLE 1 micro-radian in a dry atmosphere; 7 micro-radians at 75% relative humidity, from 50c/s to 10,000c/s for any capacitor setting.

BACKLASH Less than 0.005%.

DRIVE 50 : 1 worm reduction gear.

DIMENSIONS 12⅞" x 10" x 13⅝" (32.7 x 25.4 x 34.6 cm).

PRECISION BS INSTRUMENTS

Donaldson 6-stimuli Colorimeter

for the accurate measurement and standardisation of colour

The most accurate and reliable colour measuring instrument available for paints, woollens, textiles, signal glasses, powders, liquids, printing inks, foodstuffs, and for general research where colour measurement is important.

We shall at all times be pleased to demonstrate the above instrument at our showroom, or to give any help or advice in connection with the application of this instrument to your problems.

FOULING THE SEAS

THE Minister of Transport appointed a committee of representatives of British shipping, oil companies, dock, harbour and transport authorities and interested Government departments in September 1952, to consider and report upon practical measures to prevent oil pollution. In less than a year, a very informative report was prepared and published*, giving a clear picture of the shocking amount of pollution. The sources are examined in great detail and a long-term policy of introducing effective preventative measures is advocated. As an interim measure, immediate action is recommended prohibiting ships registered in the United Kingdom from fouling the neighbouring seas and shores. The subject was discussed at a full-day meeting in London of interested bodies on October 27 (see p. 1025).

The fouling of the seas, hundreds of miles away, damages the fauna and flora of seas and coastline, and spoils the amenities of sea-shores. The evidence is that oils causing the worst pollution are very stable; there may be slow oxidation, so slow as almost to defy detection, but these oils keep floating almost indefinitely. Oil on water in experimental tanks remained for nearly eighteen months, until the water had disappeared through seepage and evaporation. In the late summer of 1952, British oil companies carried out experiments on the behaviour and drift of oil discharged on the sea. Fifteen tons of fuel oil covered an area of eight square miles six days after discharge, and in eight days had drifted some twenty miles from the point of discharge. The proposed prohibition of discharge of oil within a prescribed zone is only a palliative, but would be a first step towards international agreement to prohibit any fouling of the seas with oil. Further experiments are being conducted with drift cards to obtain more information of the drift under the combined influences of winds and tides. The winds greatly influence drift; it is those shores exposed to the prevailing winds that are the most polluted.

Perhaps one of the most important recommendations is that the various possibilities of chemical treatment as a means of preventing pollution should be explored, and a programme of research ought to be sponsored by the Government at the earliest opportunity.

The sources of pollution have been very thoroughly investigated by the committee; analyses were made of samples of oil found on the beaches and on the plumage of sea birds, and almost without exception they had the characteristics of crude oil residue or fuel oil. One source of oil pollution is not mentioned in the report, namely, the escape of unburnt fuel through the funnels of oil-burning ships. Unburnt fuel, although only one or two per cent of the fuel consumed, may be deposited on the sea and the effect of this should also be investigated, because it is the more deleterious compounds that escape, and even one per cent of the bunker fuel is a very large tonnage each year.

---

* Ministry of Transport. Committee on the Prevention of Pollution of the Sea by Oil. Pp. v+50. (London H.M. Stationery Office 1953.) 2s. net.

Although the committee was not asked to study the damage caused by oil pollution, the ill-effects indicated in the report are: (*a*) the spoiling of beaches and the amenities of coastal resorts; (*b*) the destruction and injury of sea birds; (*c*) the fouling of boats, fishing gear, quays, etc.; (*d*) risk of fire in harbours and other enclosed waters.

The oil is also deleterious to marine flora, and the widespread disappearance during the past twenty-five years of the eel-grass *Zostera marina*, a plant of the inter-tidal zone, is believed by some to have been mainly brought about by oil pollution. The symptoms of the disease of this plant, including the final stage in which it is killed by a parasite, *Labrynthula*, are very similar to the symptoms observed on similar land plants when oil is used as the killing agent. The large areas of eel-grass provided a special habitat for fish and food for wildfowl, and the long fronds were effective breakwaters. Where large areas of eel-grass disappeared there has been a decrease in molluscs and crustaceans, wildfowl have moved elsewhere, and erosion of the coastline has often followed. The conclusions are that waste oil not only fouls, but also kills, and that the cost of the present scale of pollution of the seas of the world is such that vigorous action must be taken at once to halt this menace; and then, as quickly as practicable, on an international basis, to eradicate the sources of oil pollution of the seas.

The highest praise is due to the committee for the presentation of this excellent report within so short a time, and it is hoped that prompt action by the Government will follow, thus giving a lead to other countries on essential standards of cleanliness.

THE INTERACTION OF SCIENCE AND SOCIETY

In recent years, many papers and books surveying the impact of science on society and the influence of the modern democratic State on the progress of science have been published. Some have been confined to a narrow field of interest, whereas others have attempted a survey of the whole broad problem. A recent book on this subject is Mr. Bernard Barber's "Science and the Social Order"*; although this refers particularly to the American scene, its general conclusions are worth consideration in a wider context.

In his view of the nature of science, Mr. Barber follows Dr. J. B. Conant, whom he quotes extensively, adopting a matter-of-fact and realistic treatment which is a valuable feature of his book. He shows both the reason why science alone can never provide for man a complete adjustment to the natural and social world, and also the way in which the good conceptual schemes, which Dr. Conant regards as the essential component of all science, are interwoven with controlled experimentation in scientific advance. A clear understanding of this relation is, as he rightly insists, of great importance in considering the possibilities and technique of scientific advance, especially in the social and biological fields. It is of the greater importance because modern man has to learn not only about, but also to live with, science.

The relation between the conceptual schemes of science and the body of belief and knowledge usually termed 'common sense' is an aspect of the nature of science which is discussed more fully in his review of the development of science. Here he stresses some conceptions which he regards as essential for understanding the social aspects of science: the universality of human rationality; the continuity of the evolution of science; the importance of some social influences, including the economic factor, on the development of science; the relative autonomy of science, considered as a component of society; and the reciprocality of influence between science and the other components of society. Generally, he follows Whitehead and rejects the Marxist view that science is a wholly dependent part of society, moulded fundamentally by the economic factor; he holds that science has a reciprocal influence on the other sectors of society, and thus makes his examination of the characteristics of modern society which are favourable to the development of science more realistic. Incidentally, he brings out the significance of Sir Edward Appleton's recent plea for the pursuit of science for its own sake.

Mr. Barber believes both that only in certain types of society can science flourish, and that without a continuous and healthy development and application of science such a society cannot function properly. Discountenancing extreme statements regarding the effect of political ideology on scientific work, his general discussion of the social organization of science and the affinity between the accepted values of science or the characteristics of the scientific attitude and those of liberal societies is a wholesome corrective to some current polemics. Science, he points out, has its moral values, as well as its conceptual schemes. 'Pure' science is concerned primarily and immediately with the development of conceptual schemes, and applied science with making such schemes instruments to some purpose other than the pursuit of conceptual schemes for their own sake. The moral values of science are also involved, however, just as they are in the motivation of individual scientists, which may determine whether they adopt a career in science or in technology; and although in technology rationality may have a higher limit, other values cannot be disregarded even there.

While Mr. Barber's discussion of the role of the scientific and professional societies and their inter-relations is primarily concerned with conditions in the United States, his observations frequently have a much wider bearing and are highly relevant in considering the future of professional organizations and of scientific societies in Great Britain. The social pattern may differ; but the real problems are essentially the same, though the relative importance of particular factors may vary considerably. For example, the comparatively low prestige of all Government employment in the United States has depressed the public prestige of Government scientific research in that country, with an effect on recruitment the reverse of that which has existed in Great Britain, at least until recently.

---

* Science and the Social Order. By Bernard Barber. Pp. vii+288. (London: George Allen and Unwin, Ltd., 1953.) 20s. net.

In recognizing the interaction of science and society, Mr. Barber discounts any attempt to exaggerate the influence of social conditions on invention or discovery, and he dismisses the allegation that inventions are suppressed for narrow or selfish interests. His discussion of the technological change is, however, brief and stimulating rather than penetrating; and here again he insists on the importance of regarding all the moral values within the context of which science functions. He gives a timely warning against the danger of two extremist positions in accepting any kind of social responsibility of science: acceptance of exclusive responsibility is as dangerous as the 'ivory tower' attitude with its rejection of all responsibility for the social consequences of scientific discoveries. His discussion of what are often called the social responsibilities of science is realistic; for it is clearly impossible to predict the long-term social consequences of a particular discovery, or to dogmatize on the continuous interaction of social factors and science.

The great need, as Mr. Barber sees it, is for more understanding between the physical scientist and the social scientist. Science, he holds, has the obligation to extend its method to the study of the social and political process itself; and further, he makes the point that the social and natural sciences are not so completely separable from one another as is commonly assumed. Even the protagonists of the wholesale planning of science and those of freedom in general differ less than they think, and Mr. Barber remarks with some truth that they could probably collaborate very profitably in the kind of concrete prediction and formulation of programmes that occur daily in science. More of the method of science itself is, in fact, required at exactly this point.

Mr. Barber's critical analysis of the nature and prospects of the social sciences is the more persuasive because of its realism. He never claims too much, and he gives due weight alike to the rationality in society which gives social science its freedom to investigate rationally the very fundamentals of society, to the high degree of indeterminacy in most of the information classed as social science and to the non-rational elements in human life which are no more entirely ignorance and error than that the non-empirical elements are all 'unreal'. Natural science, he reminds us, has not yet given, and never will give, us complete control of the physical and biological universe in which we live. Knowledge does not need to be complete to be effective, and because human knowledge is only one of the factors that determine social behaviour its influence is for that reason limited; we need not fear that social science will create the possibility of complete social control. On the contrary he believes that, just as natural science has been used to give us relative abundance, social science can be used to give us freedom in the same relative measure; nor will science in our present society achieve maturity until social science comes of age with the natural sciences. One of the best auguries of that may well be the increasing awareness among social scientists of the nature of the scientific task which confronts them. Mr. Barber suggests, in conclusion, that in this twentieth century we may see the emergence of the conception of an 'order of human nature', with a fructifying influence on the development of social science comparable with that which the conception of an 'order of nature' has had on the development of natural science since the seventeenth century. His book provides evidence that this optimism is at least reasonable; the arguments merit careful study and discussion.

STUDIES IN ANTHROPOLOGY

Anthropology Today

An Encyclopedic Inventory. Prepared under the chairmanship of A. L. Kroeber. Pp. xv+966. (Chicago: University of Chicago Press; London: Cambridge University Press, 1953.) 67*s*. 6*d*. net.

THE occasion for this collection of studies on the various fields of anthropology was the organization of an international discussion conference in New York last year by the Wenner-Gren Foundation for Anthropological Research in celebration of its tenth anniversary. The authors are mostly, but by no means exclusively, American, and their contributions were prepared and distributed in advance among the members of the conference, both to provide points of departure of a series of discussions and an inventory of outstanding recent advances in anthropology. It should be noted that a detailed and lively report on the views developed during the conference itself has also been published as "An Appraisal of Anthropology Today" (Tax, S., *et al.*, editors. Chic. Univ. Press, 1953).

Owing largely, it would appear, to the traditions and circumstances of university teaching and research there, the interconnexions between the various branches of anthropology have been more effectively maintained in the United States than in Britain and the rest of Europe. This is reflected in both the wide coverage and the conscious efforts at integration which are apparent in this inventory. Thus, the papers variously devoted to aspects of human evolution, to the long-term culture history of the major regions of the world, to analyses of cultural processes and the range of factors underlying cultural variation and development show, for the most part, an awareness of problems, methods and findings in other fields. On the other hand, it can scarcely be claimed that either in coverage or arrangement this series of some fifty papers affords as well-organized and encyclopædic a view of approaches and results as could be desired. Practical and human limitations no doubt account in part for omission and defects, but the grouping of the papers into three main sections labelled "Problems of the Historical Approach", "Problems of Process" and "Problems of Application" is not consistent and fails to bring out significant distinctions among the data and problems of modern anthropology. In this way, Prof. Steward's valuable paper on "Cultural Evolution and Process" is placed under the "Historical Approach", while many of the papers listed under "Process" are, in fact, concerned with field-techniques and methodology. Nor do headings of subsections labelled "Method", "Results" and "Theory" fulfil their promise. More seriously, since the main objective of the conference, as expressed by its chairman, Prof. A. L. Kroeber, the doyen of American anthropology, was to secure the "advantage to be gained from a gathering that would envisage the field as a whole with the intent of pulling together what belongs together", and was to promote the cross-fertilization and integration of anthropological studies, there is little attempt to compare the *raison d'être* of the various approaches and formulate the real possibilities and conditions of their synthesis.

Some aspects of the fundamental distinction between historical and analytical studies in the various fields, which account for differences in the selection and handling of both biological and cultural data, are well sketched by R. Redfield in "The Relation of Anthropology to the Social Sciences and to the Humanities". But the equally important interdependence of historical and analytical studies, and the extent to which the degree of integration achieved in the descriptive studies depends on achievements in the analysis of socio-cultural processes, does not receive adequate attention. Analysis of the important distinction between the cultural and the sociological levels of analysis, on which there is a confusion that leads to misunderstanding and misdirection of effort in both field-work and theoretical studies, is also lacking. The unfortunate cleavage between ethnography and sociology that developed in American academic studies and is only slowly being remedied by the widening of anthropological and sociological theory there, accounts perhaps for the inadequate space (a single stimulating, but almost entirely methodological paper by C. Lévi-Strauss) given to the comparative study of social systems which has been so prominent in recent British anthropology.

But while omissions, some lack of balance and loss of opportunities may be regretted, this volume does include a number of admirable surveys of the achievements and trends in several branches of anthropology that are at once authoritative and critical. On evolution and variation in man there are useful studies on "Primates" (W. J. Strauss), "Race" (H. V. Vallois), "Evolution" (G. S. Carter) and "Methodology" (S. L. Washburn). Present knowledge of Old World culture history has been most competently summarized, and some of the implications concerning basic processes in cultural and social development analysed, in a series of papers by H. L. Movius, V. Gordon Childe and J. G. D. Clark. A similar conspectus is provided for the New World by Wendell Bennett, G. Caso, A. D. Krieger, Irving Rouse and G. Willey. Various anthropological approaches in linguistics are well reviewed by J. H. Greenberg, F. G. Lounsbury and A. Martinet. Several aspects of the study of the socio-cultural patterning of personality and of ethical and æsthetic values are analysed by A. I. Hallowell, Margaret Mead, F. S. C. Northrop, D. Bidney and M. Schapiro; while the application of anthropology in various fields such as medicine, industry and Colonial administration is reviewed by J. M. Tanner, Eliot Chapple, Daryll Forde and others. In all, this volume of nearly a thousand pages provides a useful guide to the approaches, problems and results in the many active fields of anthropological research. The studies for the most part maintain a high standard of clarity in exposition which will enhance their usefulness to scholars in other fields, as well as to students of anthropology. It is perhaps useful to note that the work can be obtained on special terms through membership of the American Anthropological Association.

DARYLL FORDE

BIRD STUDIES

Rare and Extinct Birds of Britain

By Ralph Whitlock. Pp. 224+85 plates. (London: Phoenix House, Ltd., 1953.) 21*s*. net.

THE title of this book is somewhat misleading since many of the birds referred to can scarcely be considered rare, though they are not generally distributed owing to their particular habitats. "Lost Breeding Species" is the heading of the first chapter, and it seems a trifle unnecessary to include here the pelican, of which there is no historical evidence that it ever bred in Great Britain. Among the other species mentioned in this chapter are the crane and the spoonbill, and also the sea eagle and osprey. So far as is known, the first two never nested in any great numbers in Britain, and since they were both esteemed as food they suffered accordingly and ceased to nest long before their feeding grounds had been seriously affected by draining. The case of the sea eagle and osprey is somewhat different, and their extermination as breeding species is a sorry story. In Scotland at least, they suffered from the opening up of the Highlands to sheep-farming and sport—grouse shooting and salmon fishing. The eagle did little harm to grouse; but it was a bird of prey and that was enough. Furthermore, it was fond of young lambs, and so, in addition to the game-keeper, the hand of the shepherd was against it; also the eggs always obtained a ready market. Charles St. John has been blamed for the extermination of the osprey in the north of Scotland; but he was not the only one who shot the nesting birds, and moreover the slaughter of Scottish ospreys in England on migration probably did much to reduce the breeding stock. Unfortunately the osprey lays a very beautiful egg, for which a good price was readily given.

The next chapter deals with "Rare and Local Nesting Species", which is more pleasant reading since a number of the birds referred to have increased (as, for example, the raven, golden eagle and bittern), the avocet has come back to nest in East Anglia, and the little ringed plover is colonizing in Britain. On the debit side the numbers of breeding corncrakes and wrynecks have greatly diminished. Agricultural changes are blamed for the decrease of the corncrake, but no one has yet explained the cause of scarcity of the cuckoo's mate. Surely the fulmar can scarcely be described as a rare or local breeding species at the present time. Dumfriesshire was the great stronghold of the black game, and it is very doubtful if the decrease had anything to do with "the growth of the human population" as the author suggests. It is quite true that draining and other agricultural changes have lessened their haunts; but before these changes had taken place the numbers were in decline.

The author is unfortunate in his quotations from F. O. Morris's book on British birds, and in this connexion it may be mentioned that the dotterel never bred in East Lothian, where there are no hills high enough, though large numbers were shot during the spring migration in the middle of the past century.

Chapters are devoted to "Continental and Allied Subspecies", "Rare Birds of Passage and Seasonal Visitors and Vagrants", and what the author calls "Eccentricities", by which he means birds that have occasionally appeared in Britain far out of their normal range. Much has been learned of late about some of the birds in the above categories from the work carried out at the trapping stations on the coast. But a word of warning is necessary in regard to the identification of rare warblers, especially those belonging to the genus *Phylloscopus*. The late Dr. C. B. Ticehurst informed the reviewer that, when he was engaged in preparing his monograph on that genus, he examined collections from all the leading museums of the world and in several instances found different ornithologists had identified the same bird-skin as belonging to a different race and even to a different species!

In the final chapter there are remarks on the effect of the changes of climate and the increase of certain birds' breeding range.

In the preparation of this work the author must have been handicapped in not having a comprehensive ornithological library at his disposal; but nevertheless he has produced a volume which will be of interest to many. The book is illustrated with more than eighty photographs of birds, all of which are of exceptional merit. N. B. Kinnear

A STATISTICAL STUDY OF THE STELLAR SYSTEM

Statistical Astronomy

By Robert J. Trumpler and Harold F. Weaver. Pp. xxi+644. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1953.) 7.50 dollars.

JUST half a century ago, Kapteyn propounded his famous theory of the two star-streams, based on an analysis of the available material relating to proper motions—the angular motions transverse to the line of sight. The theory was later developed, notably by Eddington, and these early researches form the true beginning of the modern study of the Galaxy. An alternative method of representing the systematic motions of the stars was afterwards suggested by Schwarzschild; this is known as the ellipsoidal theory, the frequency function of the linear components of stellar velocities (freed from the solar motion) being expressed in terms of a quadratic function of ellipsoidal form. A substantial part of the book is devoted to the statistical study of these two ways of describing systematic motions. In more recent times the observational astronomer has considerably increased the numerical data available for the statistician, these including radial velocities, parallaxes, apparent magnitudes and spectral types, in addition to proper motions.

Rather more than one-third of this monumental book of 644 pages (Part 1) is devoted to the general theory of statistics, with applications to many astronomical researches. This part is written with due consideration of fundamental principles and forms a fitting introduction for the professional statistician to some of the important problems with which the astronomer is confronted. Included in this part is a valuable chapter on the integral equations arising in astronomy, with sections on the solution of Volterra's equation of the first kind, and solutions by Fourier transforms, by interpolation functions or series, and by numerical integration. This part concludes with an interesting and important chapter on the testing of hypotheses, contributed by Dr. Elizabeth Scott.

A short part (2) gives a statistical description of the galactic system, the complete account of which is expressed in terms, substantially, of six variables —the three linear components of stellar velocity, parallax, absolute magnitude and spectral type.

Part 3 deals with stellar motions in the neighbourhood of the sun. The two-streams hypothesis and the ellipsoidal hypothesis are examined by the methods of Part 1 with reference to the observational material provided by proper motions and radial velocities in the first instance, and to the space-velocities of stars with measured parallaxes. Despite the relatively high errors in parallaxes, the authors appear to lay considerable emphasis on past investigations based on space-velocities. The theoretical researches of Eddington and Schwarzschild have, regrettably, no place in the book, and it may be that the mechanical methods of the statistician will not commend themselves fully to the astronomer long familiar with the mathematical elegance and descriptive insight of the classical investigations.

Part 4 gives a full and excellent account of the problems associated with the relations between luminosity and spectral type. In Part 5 the space-distribution of the stars is treated authoritatively and at considerable length, with emphasis on the extinction of light in interstellar space; this part will prove of great value in current investigations on the spatial and physical properties of the interstellar clouds.

The final part is concerned with the theory of galactic rotation treated mainly on familiar lines, with a critical discussion of some discrepancies between theory and observation.

The volume ought to prove a very welcome addition to the literature on the galactic system, the copious bibliography appended to the several parts being specially valuable. The authors are to be heartily congratulated on producing a work of such immense range. W. M. Smart

FINE PARTICLES AND STATISTICS

Small Particle Statistics

An Account of Statistical Methods for the Investigation of Finely Divided Materials. By Dr. G. Herdan; with a Guide to the Experimental Design of Particle Size Determinations, by Dr. M. L. Smith. Pp. xxiii+520. (New York and Amsterdam: Elsevier Publishing Co., Inc.; London: Cleaver-Hume Press, Ltd., 1953.) 70*s*.

STATISTICAL principles and methods found their first practical application in the biological, social and economic sciences. More recently the applied physical sciences have recognized the value of planned experimentation and statistical analysis. But this development has been hampered by the strong biological flavour of statistical text-books and by university syllabuses which produce statisticians more familiar with problems drawn from anthropometry or psychology than from, for example, chemical engineering. There is need for statistical treatment of physical, chemical and technological subjects. It requires a considerable mental effort to sustain the translation of bushels of wheat, girth of school-children or cost-of-living indexes into volumes, lengths and reaction-rates; the popularity of Brownlee's short monograph on "Industrial Experimentation" is due, one suspects, as much to its use of examples from the chemical industry as to its readable presentation of statistical methods. But it is not simply a matter of translation from one technical language to another. Apart from changes in emphasis, different statistical procedures being more important in one field of study than another, the proper choice of statistical method and the correct interpretation of statistical analysis require a close collaboration between statistician and physicist or chemist.

A statistical treatment of the subject of fine particles and granular materials, such as Dr. G. Herdan has undertaken in "Small Particle Statistics", is therefore most welcome. The only previous work with a statistical approach is Krumbein and Pettijohn's "Manual of Sedimentary Petrography"—an admirable account up to 1938, but limited to petrographical aspects and now out of date. Dr. Herdan's book covers more ground but is restricted mainly to physical processes.

The field of particle physics is especially in need of such text-books. Statistical methods are obviously important where the first step in any investigation is to take a sample of the powder or granular material; yet few workers report even the standard error of replicate measurements. A more important reason is that the mathematics of particle physics rests on the mathematics of statistics: both are concerned with frequency distributions. Dr. Herdan wants to go further: his object is "to establish the statistics of particles in the sieve and sub-sieve range as a branch of statistics, theory and practice, in its own right". This is a matter of point of view. Most people will think of the study of small particles as a branch of physics (and physical chemistry), in which much use is made of the mathematical procedures of statistics.

The author himself implicitly took the latter attitude when planning his book. He rejected the course of setting out the relevant statistical techniques and illustrating them by examples from particle physics. Instead, the framework of the book is based on the physical processes. The twenty-two chapters are grouped into five parts, the first three dealing with particle size analysis (Part 1), size-dependent properties of powders (Part 2), and size reduction, flocculation and mixing (Part 3). The statistical material is given chiefly in a block of chapters (6–10) linking Parts 1 and 2, but is further amplified in Part 4. The last part (5), written by Dr. M. L. Smith, is, in spite of its title "Experimental Design and Experimental Errors of Particle Size Determination", largely repetitive of material in Part 1, without the algebra, expanded by advice on experimental technique.

This approach was designed to meet the needs of the reader who has no knowledge of either particles or statistics; but to succeed it must have an adequate treatment of the physics of particles combined with a carefully planned presentation that avoids excessive repetition or cross-referencing. The author has not avoided these pitfalls. The impression is given that he never quite reconciled himself to a main theme of particles rather than of statistics.

Throughout the book, the discussion of particle physics, and its relevant algebra, lacks firmness; much is, in fact, a précis of published papers. There is little uniformity of treatment, the graphical or algebraic derivations of the original papers often being retained with little regard for style or conciseness. The reader is not sufficiently warned of the inadequacies of the elementary physics of processes such as sedimentation, light scattering and permeability. An insufficiently critical approach is shown also in some discussions on properly statistical questions: for example, Martin's statistical diameter (p. 67) is not the same as the mean chord, nor is equation 5.1 correct; the mean projected area (p. 95) is equal to a quarter of the surface area only for convex bodies; the light extinction method (pp. 30, 95) does not yield a distribution by surface area as defined in Chapter 4.

Nevertheless, there are many good points. The newcomer to the subject is well warned of the need for a statistical approach and will be struck by the power of statistical analysis as shown in copious examples, calculated in many cases from published, but not previously analysed, data. Those more familiar with the subject will discover many interesting and stimulating ideas, especially in the use of inequalities (Chapters 4, 15 and 16) between means and higher moments of differently weighted size-distributions as measures of spread. All will welcome the accumulation in one volume of a diversity of material.

P. G. W. Hawksley

ANCIENT AND MEDIEVAL SCIENCE IN ASIA

Eastern Science

An Outline of its Scope and Contribution. By Dr. H. J. J. Winter. (Wisdom of the East Series.) Pp. vii+114. (London: John Murray, 1952.) 4*s.* 6*d.* net.

THIS is a book small in size, but great in its conception and greatly needed. It is the first attempt ever made to set forth, in a form available for the general reader interested in the history of science, the ancient and medieval contributions of the countries of Asia. In our own time it has become an urgent necessity to correct that distorted perspective, still entertained by most Europeans, that all technology arose solely from western Europe and that it was based solely on the 'Greek miracle', the rest of the Old World having stood wondering aside, quaint and uncouth. Dr. H. J. J. Winter is one of the most eminent experts on Arabic science, and the authority of his sources is for the most part not only unexceptionable but in this book also accurately transmitted. Although the book is pioneer and preliminary in nature, it ought to be placed on the shelves of every library which has even a small section devoted to the history of science, not only in English-speaking countries but everywhere.

The first part speaks of the ancient river-valley civilizations of Mesopotamia and Egypt, dealing mainly with mathematics (and using the work of Neugebauer) and medicine. It then touches upon the ancient Indian contributions (for example, Kautilya, Susruta) before speaking of those from China, such as the astronomy of the classical period, Mohist optics and mechanics, Han harnessing technique, the alchemy of Li Shao-Chün, and so on. The Chinese theme is continued into the Middle Ages, discussing Chin dynasty writers on plants and animals, T'ang physicians, Sung algebraists and philosophers, and inventions such as those of gunpowder and printing. The longer treatment of Indian mathematics adopts the right attitude that, while some of the claims for high antiquity which Indian scholars have put forward cannot be accepted, great dependence on Greek mathematics cannot be substantiated either. The largest part of the book comes next, namely, that devoted to the contributions of the Arabs, or rather those who wrote in the Arabic language. They concern mostly mathematics, physics and medicine, for, on the technological side, the Arabs were not great innovators. This section is, of course, that in which the author is most at home, and it is excellently done.

Probably Dr. Winter's expert knowledge of Arabic science accounts for certain general nuances which at times appear. If the introduction seems unexpectedly devout, this is perhaps due not only to the series in which the book appears, but also to the Arab convention of adding, whether in a chemical or astronomical discussion, that in any case God knoweth best. But this has led the author into saying in his introduction (and his conclusion) that on the whole Asian interest in scientific ideas and methods was philosophical and æsthetic, not concerned with practical applications. Everything we know of Chinese science contradicts this, as the author himself has to recognize on p. 36. True indeed is his final conclusion that the study of Asian science makes one realize the unity of science as nothing else can, and the dependence of Europeans on Asian initiators much more often than is commonly supposed. But his picture of four consecutive stages, the Ancient Empires, Greece, Asia (especially Islam) and lastly western Europe, is not quite satisfying; surely it would be truer to say that the science of the ancient empires of the Fertile Crescent passed in both directions, to China and India on one hand and to Greece on the other, each culture-area developing them in their own way. Islam united the traditions to some extent, and certainly transmitted much from east to west.

JOSEPH NEEDHAM

HISTOLOGY IN TRANSITION

Histology

By Prof. Arthur Worth Ham. Second edition. Pp. xix+866+7 plates. (Philadelphia, London and Montreal: J. B. Lippincott Company, 1953.) 80*s*.

HEINRICH FREY in his text-book of histology published in 1874 says, "without a knowledge of composition, true scientific study of histology is impossible and the latter is in danger of degenerating into a mere toying with details". For the greater part of this century and even to-day in many medical schools in Britain, histology, certainly as it is taught to medical students, has been little more than 'toying with details'. But during the nineteenth century it was a dynamic subject: its investigators imbued with the spirit of investigation, not merely of "structural elements" but also of "the substances occurring in the latter, their introduction, origin, and the significance they possess in the life of the form and tissue elements . . . their metamorphoses, decomposition and elimination". This was a period which bred the great figures in histology: Ranvier, Müller, Purkinje, Henle, Schwann, Koelliker, Remak, and many others. It was a period when even the Royal College of Surgeons boasted a professor of histology in the form of John Quekett; when Frey and his colleagues spoke rather scornfully and apologetically of "topographical histology" and bemoaned the limitations to their discovery imposed by the modest knowledge of organic chemistry which then existed. Even so, 'histochemistry' was attempted and was in fact known by this name, and a text-book of histochemistry was published by Schlossberger.

This tradition was maintained by the publication in Britain in 1902 of Gustav Mann's remarkable "Physiological Histology" which, though primarily a book on technique, stressed the histochemical and physiological side of the subject. He complained even then that "the ordinarily accepted view that histology concerns itself merely with micro-anatomy seems to me a narrow one". Unfortunately, this view has persisted for a very long time and is only now beginning to pass through a period of transition. Part of the reason for this is that histology in Britain has never been free to develop for itself but has always been tied either to physiology or to anatomy; and yet it is a discipline very different from both these subjects and, with the rapid development of the more difficult discipline of histochemistry, it becomes more and more a subject that needs its own specialists if it is to develop as it should.

Lack of senior posts and therefore of careers in histology has been one of the major factors which have stifled the development of the subject in Britain. However, across the Atlantic, where even professors of histology exist, histology and particularly histochemistry are developing with great rapidity. A professor of anatomy in charge of histology at the University of Toronto, Arthur Ham, published in 1950 an outstanding text-book of histology which was fully in the tradition of the nineteenth-century histologists. The second edition of this has just appeared and is a large work of 866 pages and 518 figures, including seven plates in colour. The size, although it makes for completeness, is of course secondary to the content, and in this respect the second edition not only lives up to the high reputation of its preceding edition but surpasses it. Most of the sections have been enlarged and others re-written, and new illustrations have been added. The reviewer was particularly attracted by the introductory chapter, which showed the relationship of histology to other medical subjects, and by the illustrations explaining the appearance of tubes which had been cut in various ways in histological sections. The other sections of the book deal with the microscopical anatomy and the chemical nature (where this is known) of organs and tissues and their components and with their function. At the end of each chapter is a most useful list of references, and there are nearly twenty pages of subject index at the end of the book. The price of 80*s*. makes it a very expensive book for students; but there is little doubt that it is the best value of any histological book at present on the market, and it is an essential component of every histological laboratory.

G. H. BOURNE

Progrès récents de la chromatographie

Première partie : Chimie organique et biologique. Par Dr. Edgar Lederer. Pp. 146+3 plates. Deuxième partie : Chimie minérale. Par Michael Lederer. Pp. 131. (Actualités scientifiques et industrielles, 1079 and 1181.) (Paris : Hermann et Cie., 1949 and 1952.) n.p.

These two volumes on recent progress in chromatography have been prepared by authors who have themselves made significant contributions in chromatography and, taken together, form a useful guide covering the whole field of separation studies by this method. The general arrangement of subject-matter follows a similar plan in both cases in providing chapters dealing with adsorbents, solvents, techniques and a wide variety of applications. Chromatography on cellulose, which represents the most important advance in recent years, receives due notice ; but there are also chapters dealing with electrophoresis, ion exchange and earlier work on alumina and other solid adsorbents. The information provided in these books, although necessarily brief, is reliable and clearly presented. The main function of books of this kind is to stimulate the interest of the reader in what may be an unfamiliar field, to describe what has been done and to provide references to original literature where more detailed information can be found. The authors have performed this task very well ; but in such a rapidly advancing subject it is important that the work should be as up to date as possible to be of maximum usefulness. Part 1, published in 1949, loses something of its value at the present time from absence of descriptions of work done during the past few years, but forms a useful introduction to the subject. Part 2 gives a good account of inorganic chromatography up to the end of 1951. Work in the latter field has progressed rather more slowly than in organic and biological chemistry but has already proved of exceptional value in separations which are difficult to accomplish by other procedures. This little book by Michael Lederer should go far towards making inorganic chromatography better known and appreciated, particularly in France. F. H. Burstall

Introduction to the Foundations of Mathematics

By Prof. Raymond L. Wilder. Pp. xiv+305. (New York : John Wiley and Sons, Inc. ; London : Chapman and Hall, Ltd., 1952.) 46s. net.

If the question be asked whether or not this book is just 'yet another' addition to the collection of texts on fundamentals, the answer is an emphatic 'No' ; and for the following reason. Prof. R. L. Wilder has, in effect, written two volumes in one. The first, on concepts and methods, is the result of much teaching experience ; it is helpful and readable, but not particularly original. The second, however, dealing with the "development of various viewpoints" is, in my opinion, outstanding and fully justifies placing this work in a class by itself. After discussing the various 'schools' (for example, intuitionism), come some twenty pages devoted to the cultural setting of mathematics, considered both genetically and historically. Nothing quite like it has appeared since Pickford did much the same, in a monograph, for the fine arts a decade or so ago.

Broadly, the thesis is that, like other cultures, mathematics shows a growth conditioned by evolution and by diffusion. The common influences like migration, cross-infection and the like are shown to apply. Individual men of genius arose because the cultural environment 'required' them, rather than the other way round. Seen through contemporary eyes, the modern *Methodik* may soon invade psychology and the social sciences, a hypothetical movement at present, but reminiscent of the prophetic remark by the late Prof. A. N. Whitehead on a similar theme. Whatever eventually happens, Prof. Wilder's outlook is invigorating, and worthy of close attention by teachers and by students alike. F. I. G. Rawlins

A Century of London Weather

By W. A. L. Marshall. (Air Ministry : Meteorological Office, M.O. 508.) Pp. ii+103+29 plates. (London : H.M. Stationery Office, 1952.) 15s. net.

The weather of London is of interest to a good many people, especially this year, and this official compilation was very timely. It is based on the records at the Royal Observatory, Greenwich, since 1841, the Kew Observatory, Richmond, since 1871, and some shorter records for other parts of London, including Kingsway. It opens with summaries for 1841–1949, giving the warmest and coldest years, months, days and nights, extremes of rainfall, snow, thunder, sunshine, drought, frosts and fog. The section on seasons includes comparisons of the temperature and rainfall of each season with those preceding and following. There is a slight tendency for abnormal conditions to persist into the following months, but with so many exceptions that the relation is useless for forecasting. A long chapter describes diurnal and annual variation of visibility in various parts of Greater London. Frequencies of warm and cold spells at different times of the year are discussed, but little support is found for Buchan's famous spells. Nearly half the book is taken up with monthly tables of temperature, rainfall and, after 1880, sunshine for each year, 1841–70 at Greenwich and 1871–1949 at Kew, and with graphical presentations in coloured plates of most of the material in the tables. It would be difficult to think of any query about London weather which cannot be answered from this book, but an explicit reference might have been made to the question of changes of climate—for example, the index includes no reference under "old-fashioned winters".

Embryology

By Lester George Barth. Revised and enlarged edition. Pp. xi+516. (New York : The Dryden Press, Inc., 1953.) 6 dollars.

In this revised and considerably enlarged edition, the essential framework of the original work has been retained. The author's aim is to discuss the general principles of embryology and to illustrate relevant anatomical data over a wide taxonomic range. In particular, the new materials lay emphasis on the development of the nervous system and the derivatives of mesoderm ; but new and valuable additions have been made at many points. An unusual feature of the book is that, to afford students a more thorough grasp of comparative embryonic development, illustrations of the development in frog, chicken and mammalian embryos have been so arranged, on a detachable system, that any organ can be studied either chronologically through its development in one animal, or comparatively in several animals simultaneously. Both the text and illustrations are of an admirable clarity.

THE ROYAL SOCIETY

ANNIVERSARY ADDRESS BY DR. E. D. ADRIAN, O.M., P.R.S.*

AWARD OF MEDALS, 1953

Copley Medal : Prof. A. J. Kluyver, For.Mem.R.S.

PROF. A. J. KLUYVER has held the chair of microbiology at Delft since 1921 and has become a world authority on general microbiology and the biological approach to its problems.

In 1923 he made a survey of natural processes known to occur through the agency of micro-organisms, and this survey has been the cornerstone of his work for almost twenty years. Impressed by the bewildering variety of substances (both inorganic and organic) used by these organisms for their growth processes and by the equally great variety of substances formed as the end-products of metabolism, he sought some underlying uniformity in the basic types of chemical change which occurred. Devoting himself mainly to bacterial fermentations, he found this uniformity in the extension of the concepts of Wieland and Thunberg that biological oxidations occur by successive transfers of pairs of hydrogen atoms to a suitable acceptor. His views were confirmed by a series of studies covering all the principal bacterial fermentations of carbohydrate. These researches also led him to believe that, in spite of the many and varied products formed, the degradation of carbohydrate took place stepwise by a series of simple reactions leading to a limited number of common intermediates. The initial stages were alike and the variation came later through the differing enzymic constitution of the cells and the differing effects of changes in the environment on such enzyme reactions. These views have been amply confirmed and, apart from its broader implications, the work on fermentation remains a source of some of the most accurate data in the field.

Kluyver's views on the uniformity of basic cell processes in all types of cells are now widely accepted and form the basis of comparative biochemistry (a term first used by Kluyver himself). As early as 1931 he pointed out the advantages of micro-organisms for this kind of work, not only because of their biochemical versatility, but also because of the relative ease of working with them under fully controlled conditions.

Kluyver's research and thought have always been directly towards the ultimate problem of the life of the organism in its natural environment, and his broad and critical knowledge of all branches of microbiology has been an inspiration to his pupils, many of whom, in various countries, are in the front rank of microbiologists. His scientific eminence was recognized in his own country by his election a few years ago to the presidency of the Royal Netherland Academy of Sciences.

Royal Medal (A) : Prof. N. F. Mott, F.R.S.

Early in his career, Prof. N. F. Mott's work in the field of atomic collisions attracted widespread attention. He was the first to show that Rutherford's scattering law holds in quantum mechanics, and to give an accurate theory of the effect of symmetry in scattering problems. When, at the age of twenty-seven, he became professor of theoretical physics at Bristol, he abandoned this subject for that of the theory of metals and alloys, and within a few years he was recognized as one of the leading international authorities in this field. His papers on electronic bands in metals and on the electrical conductivity of alloys and its temperature coefficient have markedly influenced the lines of experimental approach in a field in which the literature was already vast. He has also contributed to the important problem of metals under strain.

Later, he turned to semi-conductors and insulators, throwing light on the physical processes involved in the formation of oxide films and in the electrical conductivity which can be induced by various means in polar crystals. His theory (with Gurney) of the formation of the latent image in a photographic emulsion has found general acceptance, and has stimulated fresh experimental work in research departments of the industry.

During the Second World War, as superintendent of theoretical research in the Armament Research Department at Fort Halstead, he made an outstanding contribution to the theory of the fragmentation of shell and bomb cases under the effect of the explosive charge, and on his return to the H. H. Wills Laboratory at Bristol he has directed work of great importance on the mechanical properties of materials. Mott's personal contributions have been mainly to the theory of plastic deformation in metals, developing the understanding of bulk behaviour in terms of microscopic derangements of the crystalline structure. His ability to establish close and effective association between theorists and experimenters is shown by the outstanding advances which have been made at Bristol under his direction, in the various branches of the physics of materials.

Royal Medal (B) : Sir Paul Fildes, O.B.E., F.R.S.

Although the outstanding contributions of Sir Paul Fildes to the science of bacteriology have come from his researches in bacterial chemistry, his earlier work on the cultural requirements of the influenza bacillus and some of its relatives added materially to our knowledge of the genus *Haemophilus*, and his brilliant studies of the behaviour of the tetanus bacillus and its spores *in vivo* and *in vitro* were a major contribution to the natural history of this micro-organism and the disease it produces.

This work brought to Fildes the conviction that full knowledge of nutritional requirements was essential for a proper understanding of the life-processes of bacteria. He gathered a small team of bacteriologists, chemists and biochemists which was formally established as a Medical Research Council Unit in 1934, and together with the late Dr. Marjory Stephenson he was largely responsible for the development of chemical microbiology in Great Britain. The period 1930–40 saw the discovery by the Unit of a number of hitherto unrecognized bacterial growth factors (for example, nicotinamide, uracil, glutamine) and the establishment of the detailed amino-acid requirements of several organisms. Concurrently, the specialized technique required was being worked out and has contributed largely to that in common use throughout the world to-day.

---

* Delivered at the Royal Society on November 30.

Fildes was always interested in the wider aspects of bacterial nutrition and early showed that organisms could be 'trained' to synthesize essential nutrients such as amino-acids. This field has been intensively developed, particularly since the advent of modern biochemical genetics, in other laboratories.

Fildes believed that the inhibitory action of some anti-bacterial agents might be due to interference with the metabolism of essential nutrients. The Unit's outstanding achievement in this field was the demonstration that sulphonamides act by inhibiting the utilization of p-aminobenzoic acid. This concept has stimulated an enormous volume of work on the possibility of designing anti-bacterial substances which might prove useful therapeutic agents or valuable tools in biochemical research, and it has also proved of great value in studying biosynthetic pathways.

Fildes's work during the War was outstanding, and since his retirement he has continued his work on chemical aspects of microbiology, and with the aid of young collaborators is adding significantly to knowledge of bacteriophages.

Davy Medal: Sir John Lennard-Jones, K.B.E., F.R.S.

Sir John Lennard-Jones's principal contributions have been to the modern theory of valency and molecular structure. In 1929 he published papers which laid down the foundations of the so-called molecular orbital method for the discussion of diatomic molecules. Among its first successes was the clarification of the triplet nature of the state of the oxygen molecule O_2. The foundation thus laid was built upon by very many authors, who applied the method to the analysis of the complex relations among the numerous group of organic compounds known as conjugated molecules. Almost an entire branch of the modern literature now consists of what are virtually applications of the original Lennard-Jones technique, and it has been shown that many subtle and surprising properties of such compounds follow from their structure in an intelligible way.

With a series of colleagues he has extended the theoretical treatment of the liquid and solid states. He has made calculations of the interatomic forces in the rare gases and other simple substances, and used the results to formulate a law of force applicable to ions in crystals. With the aid of this the lattice properties have been calculated and the results have illuminated the general picture of the solid state.

His papers on the liquid state have dealt with fundamental properties such as boiling points and critical temperatures, and further increased our understanding of the relations between molecular forces and the properties of substances.

As a complement to this abstract theoretical work, Lennard-Jones worked throughout the Second World War and after on various problems of vital practical importance connected especially with ballistics. In 1942 he was appointed chief superintendent of the Armament Research Department, where he bore extremely heavy and complex responsibilities. Later, he was chief scientific officer to the Ministry of Supply, and has now succeeded Lord Lindsay as principal of the new University College of North Staffordshire.

Hughes Medal: Sir Edward Bullard, F.R.S.

Sir Edward Bullard's earlier research work, on atomic physics, was done in the Cavendish Laboratory under Lord Rutherford, and it was Lord Rutherford who specially recommended him to Sir Gerald Lenox-Conyngham as suitable to undertake research in the Department of Geodesy and Geophysics, Cambridge. In that Department, where for some years he was Smithson Student of the Royal Society, he carried out a notable series of investigations of far-reaching importance. His clear insight and experimental skill enabled him to tackle difficult problems with a directness and freshness of approach that made them appear deceptively simple.

Bullard's determination in 1932 of the value of gravity at a number of stations in terms of the value at Cambridge was achieved by comparing the time of oscillation of a pendulum swinging at Cambridge with the time of oscillation of a similar pendulum swinging simultaneously at a field-station. These results were of considerable geophysical interest, and were followed by similar interconnexions by Bullard and others between pendulum stations in Great Britain; in 1936, the available modern gravity determinations, mainly carried out under the supervision of Sir Gerald Lenox-Conyngham, were collected and critically discussed by Bullard and Jolly, so that gravity measures in Great Britain were combined in a coherent scheme, forming a basis for later work on gravity, much of which was carried out or inspired by Bullard. The Cambridge apparatus has been lent to a number of observers in different parts of the world; the reduction and discussion of the results of some of the earlier of these expeditions (in the Sudan, Tanganyika and Cyprus) were carried out by Bullard.

In 1938 he initiated a series of expeditions in submarines for the determination of gravity at sea, using the Meinesz apparatus to investigate the continental shelf to the west of the British Isles. Meanwhile, with geophones of his own design, he delineated the palæozoic floor of East Anglia.

Many discussions had already been published of the thermal gradients in bore-holes, and it had been thought that the rate of outflow of heat differed markedly in different parts of the world; but the heat conductivity had never been measured on the actual bore-hole specimen. This unsatisfactory state of the subject was largely cleared up by Bullard, whose investigations in South Africa showed from measurements of heat conductivity of the rocks at different horizons that the rate of upward flow of heat across any section of a given bore-hole was the same. Further, a critical discussion of the data showed that the outflow is sensibly the same in all the continental regions of the globe. There remained the question of heat-flow through the ocean floor. This was first determined by Bullard in 1949; he devised a hollow steel 'spear' which could be driven vertically into the ocean sediments and left for about thirty minutes in order to reach thermal equilibrium. Experiments carried out with this apparatus in the Pacific Ocean have indicated an outflow of heat which is much the same as that through the continents, though determinations made in the Atlantic by Bullard in 1952 gave a rather lower heat-flow.

In recent years Bullard has written a number of important papers on the causes of the earth's magnetic field and, despite the heavy demands of administrative work as director of the National Physical Laboratory during the past four years, he has contrived to continue his own geophysical researches and to inspire and facilitate the researches of others.

THE GROWTH OF NATURAL KNOWLEDGE

The object of the Royal Society is the improvement of natural knowledge. It began when the search for this kind of knowledge was little more than the amusement of the curious, and we have now reached the stage when it increases so rapidly that there is not enough paper to be found for printing all that comes to light every year. It is true enough that the early virtuosi had no abundance of paper. Isaac Newton's letters, soon to be published in a collected edition by the Society, are written as closely as possible, and he and his contemporaries made their notes on every scrap of paper they could find. But what troubles us now is not the scarcity of writing material but the abundance of finished manuscript waiting to be published. We know, too, how little of it we are likely to read ; although we are bound to regret the slowing down of productive work in academic science during the war years, I think those years will be recalled by many of us as the time when we had no piles of unread journals and reprints to be ashamed of. Nowadays the piles would be even larger if publication were easier, for scientific research has become one of the major interests of mankind and we cannot escape the consequences.

One consequence, which weighs heavily on me at the moment, is that it has become increasingly difficult to pick out some special discovery or specially active line of work to bring before the annual meeting of the Royal Society. There has been great activity in many lines ; but for the time being we seem to have passed the stage of really startling discoveries. In the most promising fields there are already so many scientists at work that the general line of advance can be foreseen for a few years at least. We cannot, of course, foresee the sudden illumination which comes from time to time to put some branch of science on a new footing ; but it would be safe to foretell that very soon the chemists will have synthesized more natural products, that we shall know much more about the structure of the proteins, about the nature of viruses and the action of enzymes, about the products of atomic disintegration and the physical properties of matter at very high and very low temperatures. Valuable discoveries will certainly come in all these fields ; but we are well prepared for them : they will not startle us unless they show some fault in the accepted theories, and most of them are already based on a wide range of evidence.

The rapid expansion of scientific research has another consequence which must be of some concern to a Society which deals as we do with the whole domain of natural knowledge. In the past, it was a domain with isolated fields, each yielding a different crop and mostly separated by tracts of unexplored country. It was easy to classify scientists as chemists, physicists, zoologists and botanists, and so on. They had different data to bring together and a different way of dealing with them, with a different vocabulary and different apparatus ; as soon as we were through the door we knew whether we had come to the right laboratory. But it is becoming far more difficult nowadays to decide where the boundaries should be drawn ; the major fields are experimenting with new crops, and the barren areas which used to separate them have begun to yield fruit and to attract workers from distant regions. Mathematics and physics and chemistry lead without a break into the biological fields, and it needs more than a casual glance to tell whether we are in a laboratory which studies the atom or the human brain.

We should all rejoice that the old barriers are yielding, for we aim at a single inclusive system of the world, one that will cover all the immense variety of natural events. Yet they have an immense variety and it is still necessary to classify them. For a society like ours the classification ought not to go into much detail. There must be committees with suitable labels ; but if we are to judge the importance of different lines of inquiry there must be as much overlapping as possible, so that a new line of work can be considered by experts who are not all biased in the same direction. But in their own laboratories the different branches of science must be free to take their own course and, though the major groups are content with their traditional labels, the pioneers who work in new territories need new ones. We are all too familiar with the passions aroused at the thought of independence from 'overlords' who were once powerful, and so we cannot be surprised when a group of workers in a new field demand a label which does not saddle them with wider scientific loyalties. No one ought to, or can, stop them from having their own journals and meetings, and if they want it they must be allowed the satisfaction of using a sign language that no one else understands. The chief difficulty arises in connexion with the international organizations which maintain contact between the scientists of different countries. They perform a valuable, in fact an essential, service, and this is recognized by the financial support which they receive from national governments by way of direct subscription or indirectly by way of such bodies as Unesco. But the available funds are limited, and every year new international unions arise to claim acceptance by the International Council of Scientific Unions and of the countries which support it. Advisory bodies faced by this multiplication of clients are already finding it hard to weigh the claims of new and old, of the small bands of enthusiasts eager to meet colleagues scattered over remote countries, and of the powerful established societies with congresses attended by thousands and an elaborate organization to keep in being.

The problems of the borderline subjects and of the specialist groups are bound to grow as the content of natural science increases ; but they are signs of progress and will no doubt be settled as they arise, by reasonable compromise. I have mentioned them chiefly to emphasize the more general difficulty of keeping our enormous territory in focus. It has long ago passed the competence of one mind, and it will need a more and more highly organized co-operative effort if we are to make the best use of our time.

The ability to make such an effort is, of course, our birthright. The human brain surpasses that of other animals in its capacity for what Henry Head called 'symbolic thinking and expression' ; it is because we can communicate our thoughts that two heads are better than one, and because we can express the results in permanent form by pictures or writing that each generation has a greater store of knowledge than its predecessors. Individually we can be specialists, because, in Isaac Newton's phrase, we stand on the shoulders of giants.

We are rapidly improving the mechanical devices which ought to help this upward progress. We can pay a week-end visit to a colleague in California if our ideas are still too vague to be reduced to writing; and besides the microfilms and new printing and copying devices there are the electrical recorders which are now so often used for ensuring that no single word spoken at a scientific congress shall be lost to posterity. These potential benefits are not at the service of scientists alone, but we must assume responsibility for their introduction. Aeroplanes and tape recorders can certainly assist scientific research, but only if we keep them as servants and not as masters.

It would be easier to keep our instruments and records in their proper place if we knew more about our own capacities, about our ability to profit by discussion or to extract what we need from a store of information. We have no scale for measuring such abilities, but we have a new line of approach which will certainly help their investigation. When the British Government in 1823 gave Charles Babbage a substantial grant for his calculating machine the technical difficulties proved insuperable; but Babbage could construct a machine on paper which should have been able to solve most of the problems which are dealt with by the new electronic instruments. It could even work miracles, for Babbage pointed out that his machine could be arranged to produce at intervals of a thousand years or more a single abnormal event which might well appear to be an interference with the course of Nature. With our modern instruments, miracles of calculation are possible because the operations can be carried out at an unimaginable speed; a vast number of figures must be dealt with and some of them must be stored for a limited time, but if the machine is to be of reasonable size they must be stored no longer than they are needed and in a space which can be constantly used for new sets of figures as the calculation proceeds. Thus the record must be of a kind which will vanish instantaneously and completely when the need for it is over.

One way of achieving this is to arrange for each item to set up a cycle of operations, electrical or mechanical, which will repeat itself indefinitely at a high rate but will cease immediately when fresh items appear. In the system due to Prof. F. C. Williams, 1,000 digits can be kept alive as long as they are wanted on the screen of a cathode ray tube, and the value of each can be read with a delay of not more than a few microseconds. There would be no great difficulty in arranging so that a repetition of the cycle for an hour or more should induce some structural change in the machine, a storage which would not need a constant supply of energy to maintain it; but there would be little to be gained, for it is better that the machine should start each morning as a clean slate. Its code of instructions can be given a permanent form, but the cycles of activity which keep each digit alive are ended abruptly when the current is turned off.

The human brain can neither remember nor forget with such precision—if it could we should be in a far better position to assess its powers. There are too many variables to be considered. The items of information coming from the sense organs are not all treated in the same way: a few are given priority for the storage process and many are unnoticed; and signals which reach the brain may be stored for a time as self-perpetuating cycles of activity, but before long the traces leave some more enduring change which does not need constant renewal. Thus the telephone number we have to dial can be kept alive in our mind by constant repetition like the numbers in a calculating machine; but we cannot be sure of forgetting the number completely when we have made the call.

The formation of some kind of stable trace can be inferred from the fact that memories survive periods when the brain is almost completely at rest. We must start each morning with our brain structure modified by what happened to it the day before: the deepest sleep or anaesthesia or coma, in fact the most complete cessation of activity short of death, will not make the brain a clean slate with no traces of our mother tongue or of the manual skills we learnt in infancy. Thus we may be able to say precisely how many items of information can be carried in an electronic machine for how long, but we cannot hope to answer the same questions for the human brain until we know far more about the nature of its storage processes. What we can learn from the machines is how our brains must differ from them.

There are already some indications of the kind of alteration which may be produced in a nerve cell by repeated activity. It is well known that repeated stimulation of the nerve cells of the brain produces an increased responsiveness which can last a minute or more; and Eccles and his colleagues have recently shown that even in the spinal cord, the function of which is purely executive, a long period of inactivity leads to a loss of responsiveness which is restored by a short period of enforced activity, and when restored tends to persist for a matter of hours. What physical or chemical changes are responsible for these alterations is still unknown, but we have a new method, introduced by Eccles, for studying the biophysics of the nerve cell by the use of a microelectrode thrust into its interior. The method was first used in the study of muscle fibres: its extension to the nerve cell has already given important results and cannot fail to give more.

It is naturally more difficult to study the biochemistry of the individual nerve cell than to study its electrical properties, but the storage process may well involve a chemical as well as a physical reorganization. If the cell chemistry of a grown man can bear the mark of an infection with measles in childhood, it is not unreasonable to suppose that the nerve cell constituents are plastic enough to be modified by past activity. Evidence accumulates in favour of the view that the transmission of signals from one cell to another depends on the release from the cell terminals of stimulating molecules, and their rapid destruction by enzymes. The stimulating molecules so far discovered, acetyl choline and perhaps *nor*-adrenalin, are of relatively simple structure; but we know too little about the enzymes to be sure that the destruction of the stimulus will always proceed at a uniform rate uninfluenced by the past history of the cells.

I have reason to be impressed by the versatility of the nerve cell in relation to chemical stimuli, for I have been trying for some years to find out how the olfactory organ enables us to distinguish an immense variety of molecules brought to it in the air. The receptor cells number several millions but they differ very little in external appearance; and for a time I thought that the discrimination of one smell from another depended more on the particular regions stimulated than on the particular receptor cells. But it is becoming more and more certain that there are marked differences in the specific sensitivity of the receptors. One group will react most readily to aromatic molecules, another to particular terpenes and so on. These differences are no doubt permanent, but they show that cells which look alike may have some physico-chemical organization which makes them react quite differently to a particular stimulus. It is perhaps to be hoped that the cells of our brain have a more uniform constitution, and that memory traces depend on biophysical rather than biochemical alterations. It will certainly be easier to detect the former; yet until we know more about the nature of these traces, we cannot begin to understand what is by far the most important property of the brain.

OIL POLLUTION OF THE SEA

AT the International Conference on Oil Pollution of the Sea, which was held in the Lecture Hall of the Institution of Electrical Engineers, Savoy Place, London, on October 27, representative private citizens of many nations met together for the first time in a concerted effort to press for action on the evils caused by oil pollution of the sea. The Conference was organized by the Co-ordinating Advisory Committee on Oil Pollution of the Sea, of which Mr. James Callaghan is chairman. This is an independent Committee composed of representatives of the interests in Great Britain which are most affected by oil pollution, namely: Association of Municipal Corporations, Association of Sea Fisheries Committees of England and Wales, Council for the Preservation of Rural England, Council for the Preservation of Rural Wales, County Councils Association, General Council of British Shipping, International Committee for Bird Preservation (British Section), River Boards Association, Royal Society for the Prevention of Cruelty to Animals, Royal Society for the Protection of Birds, Rural District Councils Association, Universities Federation for Animal Welfare and the Urban District Councils Association, with individual members who are experts on different aspects of the question.

In the formation of the Committee in March 1952, the efforts of many organizations which had for years been working individually to secure a solution of the problem of oil pollution were coordinated and canalized. On July 21, 1952, the Minister of Transport announced in the House of Commons that he had decided to appoint a committee to consider what measures could be taken to prevent oil pollution of the sea, and on October 2 the constitution of this committee, which was entitled the Committee on the Prevention of Pollution of the Sea by Oil, under the chairmanship of Mr. P. Faulkner, was announced. The report of this Committee was published in July this year, and the purpose of the Conference just organized by the independent Co-ordinating Advisory Committee on Oil Pollution of the Sea, and presided over by Mr. J. Callaghan, was to bring the findings of this report before public opinion in all countries.

In opening the Conference, the Minister of Transport, Mr. Alan Lennox-Boyd, stated that it is realized in the United Kingdom that legislation is required to implement the recommendations of the Faulkner Report; but it is also recognized that action by one country alone, though important, is not enough. He then announced that the Government is taking steps to call a conference of maritime governments to consider how the trouble could be ended. He had in mind that it might be similarly organized to the Conference on Safety at Sea, held in 1948, which was followed by swift action, and concluded by stating that he hoped its recommendations would be as speedily adopted.

Lord Hurcomb, president of the Society for the Promotion of Nature Reserves and, until recently, chairman of the British Transport Commission, in introducing the report of the Minister of Transport's committee on oil pollution, stated that there is no dispute as to the gravity and extent of the mischief, nor is there any room for dispute as to the cause of the trouble or the remedies for it. The remedies are clear, and all that is needed is the will to apply them. He pointed out that the Minister's committee, which included two shipowners and two representatives of the oil companies, has stated in its report that "in recent years the nuisance has become intolerable". He expressed appreciation for the speed and admirable precision with which the committee has reported, and said that its inquiries have been thorough and it has pointed firmly and fearlessly to the remedies, after satisfying itself that those remedies are entirely practicable. Lord Hurcomb continued that the problem reduces to the fact that the only way to avoid polluting the sea, fouling the beaches and destroying birds, is not to put persistent oil sludges and waste into the ocean, but to separate them and to discharge them ashore. To prohibit discharge within a prescribed distance of particular coasts is a mere palliative, though necessary as an interim measure. It has been shown that even a limit of 150 miles would not give the United Kingdom a remedy, and the only long-term policy is to prevent the discharge of persistent oils into the sea altogether. For this to be practicable, suitable and adequate facilities for the reception of oily waste should be provided at all loading terminals and repair ports throughout the world., Lord Hurcomb concluded by stating that weary years of international argument in the hope of securing complete agreement should not be contemplated, and asked that a date for achieving the ultimate policy should not be timidly fixed too far ahead.

Mr. Donald F. Anderson, chairman of the General Council of British Shipping, spoke on the problem as the British shipowner sees it and stated that their general attitude is already known by the solid fact that British shipowners have accepted the report and recommendations of the Faulkner Committee, and that they decided as soon as it came out to put into practice some of the measures. He stressed that, though they are doing all they can to help in solving the problem, it would take more than action by British shipowners before there could be any material improvement, and he alluded to the vast amount of shipping under other flags which goes up and down the English Channel without touching the United Kingdom. He concluded by saying that goodwill among shipowners of the leading maritime countries is not enough. If the aim of preventing oil getting into the sea anywhere is to be reached, this can only be achieved if vessels of all flags are bound by a convention among all the nations with ships that sail the seas.

Sir Douglas Ritchie, chairman of the Executive Committee of the Dock and Harbour Authorities Association, pointed out how difficult it has proved to detect offenders under the Oil in Navigable Waters Act, particularly as some part of the pollution of inland tidal waters is caused by oil discharged, or escaping, many miles away at sea and being carried to the coasts. He described the facilities which have been provided for the collection of oily water in ports and stated that these have, unfortunately, not been used to any real extent. His Association welcomes the recommendations of the Faulkner Committee and has made it clear that it would be prepared to co-operate in providing, or securing the provision of, adequate reception facilities at the ports.

In May 1952 an independent Scandinavian Committee on Oil Pollution of the Sea, consisting of representatives from Finland, Sweden, Norway and Denmark, was set up at an international meeting of sportsmen in Finland. This committee was represented at the London Conference by its chairman, Captain Berno von Bornstedt, and Major Bertil Funck (Sweden), with Mr. Mogens Blach, director of the Port of Copenhagen, and Mr. Moltke-Leth, of the Danish Hunting Society. Mr. Blach described the havoc caused by oil pollution on Danish shores and mentioned the voluntary efforts in abstaining from the discharge of waste oil made by Danish shipowners. He said that it is understood in Denmark that the evil cannot be eliminated until international agreement is reached, and it is felt that it is the duty of any interested country to do everything possible to have the question dealt with on an international basis. Major Bertil Funck outlined the measures regarding oil pollution which have been taken in Sweden and referred to the recommendations which were made at the Baltic and International Maritime Conference in Stockholm in 1951. He stated that the Scandinavian Committee supports the recommendations of the British report and proposes that the Scandinavian Governments should, as soon as possible, seek the agreement of the Baltic and North Sea countries for fixing a date after which discharge of persistent oils into the sea should be prohibited.

A report from Mr. Banks Belt, chairman of the Atlantic Waterfowl Council, New York, directed special attention to the need for educating crews in care in preventing oil pollution.

Dr. H. Lillie, formerly a surgeon with an antarctic whaling fleet, urged that whatever legislation is introduced internationally should cover operations of the whaling industry in the Antarctic and other seas. He described half-grown seals covered in a thick tarry mess, their eyes bloodshot with irritation, and penguins hopelessly clogged waiting a slow death.

Sir John Simonsen, speaking on the need for further research, stated that the separation of oil–water emulsions is not a problem easy of solution. What is required is a plant cheap to buy, occupying little space and requiring for its operation the minimum of technical control. Plants and methods are in use which have proved successful, but further work is necessary. If governments insist, and it is hoped they will, that oil pollution must cease, research on this problem might well be undertaken in a government research institute. It would require the joint work of a physical chemist and chemical engineer. Two speakers described plants for dealing with waste oil; and Mr. W. Killner stated that the process he has developed while in Admiralty service does not require specialized technique or elaborate equipment and is suitable for use in merchant ships. Full information is in the hands of the National Research Development Corporation.

At the close of the Conference a declaration of aims was unanimously adopted, supporting the view that ships of all nations should be required to refrain from discharging persistent oils into the sea, noting with satisfaction the co-operation of the shipping industry and oil companies, recognizing the need for international agreement and undertaking to stimulate public opinion regarding this, welcoming the announcement of the Minister of Transport regarding the calling of an international conference and urging that statutory provision be made to ensure adequate facilities for the reception of oily residues at ports, oil-loading terminals and repair yards.

In addition to the representatives of Belgium, Denmark, Finland, Sweden, Norway, the Netherlands and South Africa who attended the Conference, twenty-six nations were represented by observers from their embassies, legations, diplomatic missions and high commissioners in London.

STANDARDIZATION OF RADIOACTIVE ISOTOPES IN GREAT BRITAIN

By W. E. PERRY

National Physical Laboratory, Teddington

SINCE the end of 1950, four organizations in Great Britain—Atomic Energy Research Establishment, National Physical Laboratory, Radiotherapeutic Research Unit of the Medical Research Council and Royal Cancer Hospital—have been collaborating in the measurement of radioactive isotopes on an absolute basis, that is, in determining the number of disintegrations per second in a given sample. It seems an appropriate moment to review very briefly the work which has been done so far; a fuller report on the measurements (up to the spring of 1953) is obtainable on application to the Director, National Physical Laboratory, Teddington.

The impetus for undertaking this work came partly from the recommendations of the Joint Commission on Radioactivity and of the International Commission on Radiological Units. The aim has been to assess the reliability of different methods, to improve and develop them, and to introduce ultimately a system of standardization appropriate to the more important isotopes, particularly those of relatively short half-life. Some users of radioactive isotopes are, of course, not much concerned with absolute values; but others, for example, clinical users, must have an absolute basis for their work with these substances.

At the outset a short list of the more important isotopes was drawn up, and it was hoped that an accuracy of the order of 2 per cent would be both adequate and attainable in their standardization. By the end of 1952, samples of ten isotopes had been measured by counting and by ionization-chamber methods. The former included defined solid-angle β-particle counting with end-window Geiger–Müller counters, 4π-solid angle β-particle counting with Geiger–Müller and liquid scintillation counters, and $\beta\gamma$-coincidence counting. The samples were solutions prepared and distributed by the Atomic Energy Research Establishment, their activities ranging from about 0·1 to 8 mC. per gm. of solution.

The work has shown that the defined solid-angle method is not satisfactory for absolute measurements, owing to the complex absorption and scattering conditions; it may, however, have a use as calibrated equipment. 4π-counter measurements have, on the whole, been satisfactory; thus sodium-24, phosphorus-32, bromine-82, strontium-90 and gold-198 have given values agreeing within about ±2 per cent; differences of about ±3 per cent have been found with potassium-42, cobalt-60, strontium-89 and iodine-131. Some inconsistencies may have been due to the chemical and other changes occurring during the dilution of solutions to the low level of activity required for the preparation of the sources.

The $\beta\gamma$-coincidence values for sodium-24 and cobalt-60 determined by two laboratories have generally agreed to within ±1 per cent; but for isotopes with more complex modes of disintegration, the differences have been several per cent. There has been a tendency for the $\beta\gamma$-values to be greater than 4π-counter values; for cobalt-60, this may perhaps be due to the absorption of β-particles in the solid material in the source itself. It is hoped that improvements in technique will determine and remove these differences.

The γ-ray ionization measurements have been consistent to within ±1 per cent for sodium-24 and cobalt-60 and ±2 per cent for other isotopes. This method is indirect and involves a number of physical quantities, uncertainties in the numerical values of which preclude strict comparison with the direct-counting methods. However, taking these limitations into account, no serious discrepancies have occurred between the two types of measurement.

Following the measurements of the iodine-131 samples, it was decided to revise the British standard for this isotope[1], and responsibility for its maintenance and the issue of standard samples was undertaken by the National Physical Laboratory. No formal specification of other standards has yet been made. The National Physical Laboratory has, however, begun the periodic issue[2] of phosphorus-32 samples calibrated by the 4π-counter method.

During 1953 the scheme of measurements has been continued with the same group of isotopes, and samples have been interchanged with the U.S. National Bureau of Standards and the Atomic Energy of Canada, Ltd. A report on these measurements will be made in the near future.

NEWS and VIEWS

Zoology and Applied Entomology at the Imperial College, London:

Prof. J. W. Munro, C.B.E.

The retirement of Prof. J. W. Munro from the chair of zoology and applied entomology at Imperial College of Science and Technology, London, brings to an end a long association with the College. After a period as assistant professor of entomology, he succeeded Prof. F. Balfour Browne as professor of entomology in 1929, and in 1934, on the retirement of Prof. E. W. MacBride from the chair of zoology, he assumed responsibility, as professor of zoology and applied entomology, for teaching and research in zoology as well as in entomology. The appointment of Prof. Munro marked not so much a new phase in the development of the Department as a re-affirmation of the purpose of the College "to give the highest specialized instruction, and to provide the fullest equipment for the most advanced training and research in various branches of science, especially in its application to industry". It is against this background that Prof. Munro's achievements are to be recognized. With foresight and method he brought his experience as a forest entomologist to a different field, that of the study and control of the insect pests infesting stored food and other products, and as an essential part of his provision for the training of applied entomologists he built up during the years preceding the Second World War an extremely active Biological Field Station at Slough. The work carried out there laid a firm foundation for the control of stored products pests, and it was a fitting tribute to him that after the outbreak of war in 1939 the organization passed smoothly and efficiently into new control and became the Pest Infestation Laboratory of the Department of Scientific and Industrial Research.

After the War, undaunted by difficulties, Munro set himself the task of building up another field station, at Silwood Park, fully capable of carrying on the tradition established at Slough. With the heavy responsibilities of his duties as director of the Field Station added to those he bore as head of the Department of Zoology and Applied Entomology, and with the essential burden of maintaining an intimate connexion with industry, it was inevitable that Munro's personal researches should suffer; but it is gratifying that the stimulus and opportunity he gave to others, together with his wise and patient guidance and an outlook which passed beyond the walls of the laboratory, has resulted in a body of original work and endeavour of which he may be justly proud. Throughout the Commonwealth the number of Imperial College-trained field entomologists bears witness to Prof. Munro's success in guiding and promoting the training of his students. He has held the balance fairly between laboratory discipline and field studies, and his students have been able to acquit themselves well in widely differing fields of work. Prof. Munro was made C.B.E. in 1950.

Dr. O. W. Richards

Dr. O. W. Richards, who succeeds Prof. J. W. Munro, is well known as a distinguished entomologist. A graduate of Oxford, he became lecturer in entomology in the Imperial College in 1931, received his doctorate in 1934, and was appointed assistant professor in 1938. For many years he has been closely associated with the activities of the Royal Entomological Society, becoming a Fellow in 1924, secretary during 1937–40, and serving for three terms of office on its Council between 1931 and 1945; he was vice-president in 1935. Richards is perhaps best known for his interest and work on the biology of the Hymenoptera. He has carried out revisions of hymenopteran genera, and while holding a Leverhulme research fellowship visited British Guiana before the War in pursuit of his studies. A recent book on the social biology of insects testifies to his scholarship. But his interests are wider than this. He has worked on the flour-moth *Ephestia*, on population studies of the grain weevil *Calandra*, and on the butterfly *Pieris* and its parasites. More fundamental than this, he has shown a keen interest in problems of speciation and the mechanisms of evolution. He will bring to his new appointment a wealth of taxonomic and ecological experience, and this, together with the experience gained from his close association with the development and work of the College Field Station, will ensure the continued success of entomology at the Imperial College. With the support of his colleagues in the field of insecticide research, and with the encouragement of physiological studies, the Imperial College will remain an important centre for applied entomology. Biologists will wish Dr. Richards every success in the onerous task of maintaining the high level of attainment achieved by Prof. Munro, and of holding a just balance between the varied activities of the Department of Zoology and Applied Entomology.

Cancer Research in the University of Leeds: Prof. R. D. Passey

After more than a quarter of a century of versatile directorship and distinguished personal research, Prof. R. D. Passey, the first holder of the chair of experimental pathology and cancer research in the University of Leeds, is retiring. Coming from the School of Pathology at Guy's Hospital, in London, which was already notable for the classical researches and prescient writings of the late G. W. Nicholson on tumour formation, Passey brought to his Department in Leeds those attributes of intellectual integrity, critical faculty and a broad biological approach which have distinguished his own researches and shaped the development of his Department. Largely financed by the Yorkshire Council of the British Empire Cancer Campaign, the Department has attained increasing eminence for its contributions to our knowledge of cancer in many and diverse directions. These have included the chemical induction of tumours of the skin, mamma, bladder, liver and connective tissue; the role of hormones in the genesis of tumours of the mamma and testis; the structure, frequency and causation of cancer of the lung; the experimental induction of melanoma; enzymes and tumour metabolism, and the metabolism of chemical carcinogens; the milk factor in mammary tumours in mice, and a search for a similar factor in human material; and the physical and chemical properties of connective tissue which may have a bearing on the invasiveness of cancer. In not a few of these researches Passey himself participated, and to all of them he contributed by his encouragement, his wide biological knowledge, his critical judgment and his love of truth. Of special merit has been his healthy scepticism towards ill-founded claims for the discovery of 'causes' of cancer: for example, he showed that Fibiger's 'Spiroptera cancer' of the stomach in rats was not, in fact, cancer; and he was foremost also in showing that the transfer of tumours by frozen-dried tumour tissue was not due, as Gye claimed, to a causative virus, but to the survival of tumour cells. A scientist cannot but feel satisfaction in having built up from its beginnings a Department with such a record of achievement and with a world-wide reputation as a centre of sound research.

Prof. H. N. Green

Prof. H. N. Green, who succeeds Prof. Passey, has held the chair of pathology at the University of Sheffield, previously held by Sir Howard Florey, for the past seventeen years. During this period several hundred contributions to pathological literature and to that of experimental medicine over a very wide field have emanated from Prof. Green and his staff. His early researches with Sir Edward Mellanby at Sheffield were mainly concerned with nutrition, and he published a variety of papers dealing with diet and infection, diet and pregnancy, and the biochemistry of vitamins A and D. Later, he became a demonstrator in the University of Cambridge and there, while working on bactericidal factors in the blood, became interested in chemotherapy. He has contributed in several papers to our understanding of the mode of action of sulphonamides and related compounds. During the Second World War he was asked by the Medical Research Council, with which he has had long associations, to organize a team for the study of traumatic shock. Clinical investigations led to pure laboratory studies in which the shock-inducing action of adenosine triphosphate was discovered. Green later commanded the British Traumatic Shock Team, 2, R.A.M.C., and directed investigations in battle zones in North-West Europe. All these extensive studies on shock culminated in the book, "Biological Actions of the Adenine Nucleotides", by Green and Stoner (1950). Green was also director of the Sheffield Cancer Research Laboratories; and the Annual Reports to the British Empire Cancer Campaign from 1937 until 1952, and his progressively increasing number of papers in this field, reflect his mounting interest, now demonstrated by his acceptance of the chair of experimental pathology at Leeds, and director of cancer research at both Leeds and Sheffield. Though running a large research and teaching department, Prof. Green has always taken a large part in the medical affairs of the University, the hospitals and the region.

Discovery: Mr. William E. Dick

Discovery, the successful monthly journal of popular science, completes its tenth year of continuous publication in its present form with this month's issue. That there is probably no better journal of its type in the world is entirely due to the efforts of its editor, Mr. William E. Dick. He has run *Discovery* almost single-handed since it was restarted in 1943. (Except for its name, the journal has little resemblance to the pre-war *Discovery*, which was wound up for lack of support in 1939.) Mr. Dick is a biologist by training. He took an honours degree in botany with zoology and geology at the Imperial College of Science and Technology after winning a State Scholarship at the age of fifteen. But this bias is not reflected in the contents of *Discovery*, which cover the whole field of pure and applied science. Through his personal contacts with scientists and science writers, Mr. Dick has moulded *Discovery* into a journal which is entertaining, educational and influential. He has probably done more than anyone to encourage British scientists to explain their researches in a written form understandable to the public.

While not designed as a medium for the publication of original work, *Discovery* has from time to time been first with significant scientific news. It was, for example, among the first to print the disturbing facts about the sulphur shortage. It campaigned—with apparent success—for the appointment of scientific attachés in British embassies and for experiments on the underground gasification of coal. It has campaigned, so far unsuccessfully, for better pay for science teachers. With its vigorous editor and an established readership at home and abroad, *Discovery* can be expected to improve both its circulation and its beneficial influence.

Research in Industry

On November 27 the members of the Advisory Council of Scientific and Industrial Research and the chairmen and directors of some forty research associations of the Department of Scientific and Industrial Research held a conference in London, at which they discussed in private the education of technologists and technicians in Great Britain. At the luncheon given in conjunction with the conference, Sir Ian Heilbron, chairman of the Advisory Council, made public the important news that, subject to Parliamentary approval, the Government has decided to allow the Department of Scientific and Industrial Research to plan its work on a five-year basis, thus giving a continuity and flexibility of policy which the Department has long sought. At the same time the Government is restoring in full the financial cuts made two years ago in the Department's post-war programme for the expansion of its work. After expressing his gratitude to the Government for thus generously implementing the Department's aims, Sir Ian went on to deplore the lack of recognition given by industry in general to the work of scientists and engineers. This is particularly reflected, he said, in the fact that few of the board-rooms in industry contain directors who are persons with high technical qualifications. The other speaker at the luncheon, Lord Woolton, who was deputizing for the Lord President of the Council, stressed the importance of technological education as a key factor in industry and hence of Britain's ability to keep its place in overseas markets in the face of rapidly growing foreign competition. He urged that universities, in particular, should not be averse to the giving of academic rewards to students who want to specialize in a technological field to the exclusion of other subjects.

Education in Meteorology

The third annual dinner of the Royal Meteorological Society held on November 20 had this year for its theme "Education in Meteorology", and the guest of honour was Dr. K. W. M. Pickthorn, Parliamentary Secretary to the Ministry of Education. The president of the Society, Dr. O. G. Sutton, in proposing the toast "Education in Science", said that he wonders whether we are not in danger of losing touch with reality by our search for ultimate reality, and whether it would not be worth while to turn some of our attention from the remote, unsubstantial world of atoms and electrons to more friendly and familiar things, to the clouds and the rain and the skies. Meteorology, which has been so neglected in British universities (with certain exceptions), might well, in his opinion, provide the necessary relief from over-specialization. To be a meteorologist one needs to be a very widely read scientist, for there is scarcely any branch of physics which is not involved in meteorology—it even touches on life itself.

Dr. Pickthorn pointed out that there seems to be broad divisions among school-children between born scientists, who would pursue a scientific career irrespective of their schooling, those who would never become scientists, and a very considerable intermediate body who ought to be scientists and could be, given proper training. He believed that, in teaching science, laboratory work could be supplemented by meteorological observations, and he thought that even the quite unscientific might be given some notion of how scientists think and work if their interest in the weather could be exploited. Sir Charles Morris, vice-chancellor, University of Leeds, contrasted the positions of pure and applied science in the United Kingdom and stressed the difficulty experienced in attracting students of sufficient calibre towards research in applied science. He felt that the Royal Meteorological Society by its very closeness to Nature could do a great deal in correcting this bias. Appreciation was expressed by Dr. John Brown, chief education officer of the London County Council, for the Society's Popular Lecture, arranged each year for the benefit of sixth-form pupils. The application for tickets this year has been so heavy that a repeat lecture will be given in the County Hall Lecture Theatre.

Science Masters' Association: Annual Meeting

The annual meeting for 1954 of the Science Masters' Association will be held in Oxford during December 29, 1953–January 1, 1954, under the presidency of Sir Cyril Hinshelwood. The meeting will open with Sir Cyril's address, given at 8 p.m. on December 29, his theme being "Thoughts on the Evolution of a Scientific Problem". On the following day, J. P. Stephenson and R. Thurlow will demonstrate experiments, afterwards on exhibition in the Clarendon Laboratory, at a lecture entitled "Experiments in Elementary Physics", which will be of special interest to those teaching in secondary modern schools. On December 31 the annual business meeting of the Association will be held; in the late afternoon the Association's report on "The Teaching of Science in Secondary Modern Schools" will be introduced by some of the members of the committee responsible for the report and will afterwards be critically reviewed by a headmaster of a secondary modern school. Each morning at 10 a.m. there will be three simultaneous lectures on biology, chemistry and physics, respectively; in addition, it will be possible to visit laboratories in the University and discuss problems with the University staff. The afternoon visits will be made to places of interest in Oxford and farther afield. Three exhibitions will be held concurrently with the meeting: in the Dyson Perrins Laboratory the usual exhibitions of apparatus and books by manufacturers and publishers; in the Inorganic Chemistry Laboratory the usual members' exhibition of apparatus and teaching aids; and, also in the Inorganic Chemistry Laboratory, a special exhibition by the Scientific Department of the National Coal Board showing the biological, chemical and physical apparatus and research experiments (with demonstrations) used in the routine and the research laboratories of the Department. Accommodation is available during the meeting at Keble College. Further information can be obtained from the annual meeting secretary of the Association, W. G. Rhodes, Park View, 318 Granville Road, Sheffield 2.

University of Glasgow

MR. HAROLD J. TRUMP has been appointed director of extra-mural studies in the University of Glasgow, in succession to the late Dr. W. S. Evans. Lecturers, in the subjects as shown, have been appointed in the University as follows: *Senior Lecturer*, Dr. Ian M. Dawson (electron microscopy); *Lecturers*, R. Common (geography), R. H. Cummings (geology), B. E. L. Deckker (mechanical engineering), W. M. Fairbairn and A. Geddes (mathematics), A. Fraser (agricultural zoology), K. M. Guggenheimer (natural philosophy), R. G. Hemingway (agricultural chemistry), G. W. Hutchinson (experimental physics), J. J. Lewis (pharmacology), Alfred Marr (veterinary medicine), R. G. Moorhouse (theoretical physics), G. H. Nancollas (chemistry, in succession to the late Dr. J. C. James), and J. E. Tinne (bacteriology). In the Department of Natural Philosophy, the following appointments have also been made: A. H. De Borde and Derek Oldroyd (Nuffield Fellows) and W. G. V. Rosser (D.S.I.R. Research Fellow). For the present session 259 new students have been admitted to the Science Faculty of the University (198 men, 61 women); the total number of students registered in the University as a whole is 5,586 (4,364 men, 1,222 women).

Colonial Service: Recent Appointments

THE following appointments have recently been made in the Colonial Service: R. B. Jagoe (senior botanist, Federation of Malaya), chief research officer, Federation of Malaya; L. H. N. Larter (botanist, Department of Agriculture, Federation of Malaya), senior botanist, Department of Agriculture, Federation of Malaya; J. C. Parisinos (temporary agricultural superintendent, Class 1, Cyprus), agricultural officer, Class 2, Cyprus; A. W. Burtt (chief chemist, Singapore), director of chemistry, Federation of Malaya; C. Cairns (assistant conservator of forests, Federation of Malaya), conservator of forests, Federation of Malaya; E. J. Strugnell (conservator of forests, Federation of Malaya), deputy director of forestry, Federation of Malaya; W. A. Dos Santos (pathologist, grade *B*, Trinidad and Tobago), pathologist, grade *A*, Trinidad and Tobago; W. G. Barnard (principal veterinary officer, Swaziland), deputy director of veterinary services, Tanganyika; E. C. S. Dawe (deputy director of veterinary services, Tanganyika), director of veterinary services, Tanganyika; Che Mohd Harun bin Taib (extra assistant conservator of forests, Federation of Malaya), assistant conservator of forests, Federation of Malaya; L. Humphrey (senior assistant meteorological officer, Gold Coast), senior meteorological officer, Gold Coast; P. W. A. Davies and J. A. N. Wallis, agricultural officers, Kenya; M. J. Hannagan, agricultural officer, Tanganyika; A. R. Humphrys, agricultural officer, Uganda; T. Tait, agricultural officer, Nigeria; D. R. Williams, animal geneticist, Department of Agriculture, Nigeria; G. Youatt, chemist, Agricultural Service, Federation of Malaya; D. A. Jones, field geologist, Sierra Leone; J. E. Mason, geologist, Somaliland Protectorate; G. T. Wood, geologist, Federation of Malaya; C. A. C. Mims, medical research officer, grade 3, East Africa High Commission; B. D. Rennison, zoologist, East Africa Tsetse and Trypanosomiasis Research and Reclamation Organization, East Africa High Commission; D. G. Cochrane, scientific officer, East Africa High Commission.

Announcements

MR. EDWARD GILES GRIFFITHS has been appointed agricultural adviser to the United Kingdom High Commissioner in New Zealand, in succession to Mr. Donald S. Hendrie, who is returning to the United Kingdom. Mr. Griffiths is a graduate of King's College, Newcastle upon Tyne (University of Durham), where he was also awarded the Nathaniel Clark Scholarship. Since May 1949 he has been assistant county agricultural officer (advisory) to the Norfolk Agricultural Executive Committee. He was a member of the Anglo-American Productivity Team that went to the United States in 1950 to study productivity in farming.

A CONFERENCE on the North Sea floods has been arranged by the Institution of Civil Engineers, and will be held at the Institution during December 16–17. Twelve papers will be presented for discussion. Those who are not members of the Institution may attend the conference provided they have made prior application to the Secretary of the Institution at Great George Street, Westminster, S.W.1, from whom further information can be obtained.

THE Massachusetts Institute of Technology is offering a small number of scholarships to university graduates in science, technology and architecture to enable them to attend the summer session of the Institute during June 6–September 18, 1954, for the purpose of carrying out research. The scholarships are open to British citizens less than thirty-two years of age, who have had at least two years experience in postgraduate research, either industrial or academic. Application forms, to be completed by January 4, can be obtained from the Cultural Affairs Officer, Room 302, 41 Grosvenor Square, London, W.1.

UNDER the provisions of the Fulbright Programme, travel grants are available to citizens of the United Kingdom and British Colonies to go to the United States for an academic or educational purpose, provided that they have the financial support in dollars for the visit and are affiliated to an American institution of higher learning. The grants cover the cost of direct travel from the candidate's home to America and return, and are available during June 1, 1954–April 1, 1955. Applications must be submitted by March 15, 1954 (for those travelling between June 1 and July 31) or June 1 (for those travelling after August 1). Further information can be obtained from the United States Educational Commission in the United Kingdom, 55 Upper Brook Street, London, W.1.

THE Royal Aeronautical Society is reviving its previous custom of holding an annual juvenile lecture, which this year will be by Sir Leonard Bairstow, speaking on "The Fun of Finding Out in Flying". The lecture will be given at 3 p.m. on January 7 and will be free. Tickets can be obtained from the Secretary, Royal Aeronautical Society, 4 Hamilton Place, London, W.1.

ERRATUM. In the communication entitled "Fine Structure of the Extra-terrestrial Radio Source Cygnus I" by R. C. Jennison and M. K. Das Gupta in *Nature* of November 28, p. 996, the measurements illustrated as 51′ (twice) and 30′ (twice) in Fig. 2 should read 51″ and 30″; these are correctly quoted in the text.

DYEING AND TANNING

THE Faraday Society held a General Discussion on "Dyeing and Tanning" in Leeds during September 8–10 under the chairmanship of the president of the Society, Sir Hugh Taylor. The Discussion was well attended and included a number of distinguished foreign visitors. The introductory lecture was given by Sir Eric Rideal, and, in all, twenty-two papers were read; these will be published in due course by the Society.

The picture of the theoretical aspects of dyeing and tanning arising out of the meeting showed that, while the general nature of these processes is well understood, a great deal of detail still requires filling in. This is especially true of tanning, where the nature of the natural tanning material is so complex. The points of interest arising from the two different subjects are best treated separately.

Dyeing Processes

The mode of attachment of the dye is still a subject for speculation and may range from a straightforward partition in the case of non-ionic dyes, or Donnan distribution for ionic dyes, to adsorption on specific sites, the extreme case being Langmuir adsorption. Non-ionic dyes absorbed by cellulose acetate and polyethylene terephthalate are examples of the former, and it was shown that the addition of benzoic acid alters the equilibrium partitions ratio. On the other hand, in the case of wool, resolution of optical antipodes on adsorption shows that specific sites must exist although, as the adsorbed molecule becomes larger, the resolution becomes less. Prof. W. Bradley interpreted this as due to a lower tendency for the larger molecules to be adsorbed on sites. There is, of course, a great deal of evidence to show that sites can exist. Both on synthetic and natural fibres in acid dyeing, the total dye uptake is stoichiometric with certain 'active' groups. The importance of the effect of the fibre constituents on fibre structure as well as their chemical nature, however, was emphasized by Dr. C. H. Bamford *et al.*, who have examined the dyeing behaviour of a number of synthetic polypeptides. The use of the surface balance, too, was described to demonstrate interaction between active groups in dyes and fibres, and on a similar topic Dr. Conmar Robinson demonstrated on the macro-scale stereochemical effects with an ingenious modification of the Stuart-type model. This allows a limited amount of deformation of the bonds such as does actually occur. One striking example was the easy manner in which one may be misled as to the stereochemistry of the adsorption of an azoic dye on cellulose.

So far as the equilibrium of adsorption is concerned, it appears that there is little to choose between the various theories on fundamental grounds because of the difficulty in devising critical experiments, and a choice is usually made on the grounds of expediency. One of the main obstacles is lack of knowledge of the state of the dye in solution. Thus R. H. Blaker *et al.*, in considering the adsorption of acid dyes by coppered polyacrylonitrile fibre, postulate a variation of the activity coefficient by a factor of 600; A. N. Derbyshire and W. J. Marshall, in attempting to measure thermodynamic changes by direct thermal measurement, noted an extraordinarily large heat change on dilution of orange II (normally considered a non-aggregating dye), and Dr. A. B. Meggy described experiments on partition measurements and the effect of sodium sulphate on the solubility of this dye, from which he attempted to gain information on the activity coefficient. Further refinements in the thermodynamic treatment of adsorption data therefore await more complete knowledge of the activity coefficients of dyes in solution.

The rate-controlling steps in dyeing are now fairly well understood in the general sense, and Sir Eric Rideal showed how in many cases the rate of agitation can be a rate-controlling factor due to the relatively large distances the dye must be transported and the low concentration gradient in the external liquid phase. In these circumstances a conventional hydrodynamic flow treatment can be used satisfactorily to determine the thickness of the stationary layer. Diffusion within the fibre is fundamentally more complex, although it appears that the diffusion of acid anions is accompanied by adsorption on fixed sites. R. F. Hudson considers that, when appropriate allowances have been made, the 'free diffusion coefficient' is of the same order as that in water. He also accounted for an observed increase in activation energy with molecular size as due to deformation of the polymer chains by the larger molecules. It is interesting to note that radioactive tracer techniques are being applied to both equilibrium and rate measurements; but on the whole this technique is at present applied only as a refinement on existing ones. An interesting topic in kinetics is a study of absorption of aqueous solutions by dry cellulose, and, although the experimental technique is such that the results cannot be considered as quantitative, such studies must be of great practical and theoretical importance.

Tanning

Tanning is a relatively complex process, and the system presents greater difficulties than dyeing. It is, however, now clear that tanning processes which involve the combination of chrome and other metal complexes depend greatly on the form which the complex takes. K. H. Gustavson showed that the strong reaction of the cationic complexes of chromium is due to an initial adsorption on to single carboxy groups of the collagen, and afterwards the carboxy group enters the chromium complex irreversibly to give a strong covalent linkage. Special considerations, however, make it probable that less than 10 per cent of the total chromium complexes actually form cross-links. The slow nature of the covalent reaction is confirmed by J. Pouradier's study of the interaction of chrome and gelatine whereby he has found that viscosity increases occur over several hours.

The surface balance is being used in tanning as well as dyeing studies. By its means, J. H. Schulman and M. Z. Dogan have examined the effect of *p*H on the cross-linking of various fatty-acid and protein monolayers by a variety of metal ions, while S. C. Ellis and K. G. A. Pankhurst, by the same technique, supplemented by measurements of surface potential charges, have examined the effect of vegetable tannin on collagen monolayers.

One further technique of interest which must be mentioned is that of D. M. B. Armstrong, who described a pyknometric technique of following the diffusion of tannins into hide. In this way he has been able to follow the various steps in the tanning process and show that tanning with tannic acid is much more complicated than with Mimosa tannin.

W. J. Marshall

FIELD STUDIES IN URBAN AREAS

THE Joint Biology Committee consists of representatives of twelve organizations interested in the teaching of biology. It has now held ten public conferences. While the latest, which was held at University College, London, on October 24, and which was well attended, did not contribute much to the solution of the major problem for which it was convened, it threw light on a number of subsidiary issues which merit attention both by teachers and biologists in general.

In his opening address, R. S. R. Fitter said that although the Industrial Revolution might have driven Nature away from urban areas, there has been a vigorous return. Towns provide special opportunities for the study of processes of biological adaptation to changing conditions. He instanced the house-martin and rock pigeon, dwellers of rocky cliffs, that have taken readily to buildings, and the Oxford ragwort, the natural habitat of which is the lava flows of Sicily but which now is equally at home on sites reduced to rubble by air raids. Town sites tend to encourage a pioneer flora; in fact, modern civilization has greatly extended the area open to plants falling into this group, while upon any site the temporary associations so established are themselves subject to rapid change. He suggested that urban areas provide many opportunities for the study of local geology and geography, together with that of certain plant and animal species. He appreciates the limitations imposed by urban conditions; but he is inclined to view them as a challenge, emphasizing that a great deal still has to be learned about the natural history of even such common animals as the starling and house sparrow.

Miss M. Collis dealt with biology teaching in the secondary modern school, selecting for special consideration the claims of children in the *C* and *D* streams who might find it difficult to read and write. Yet work with them she feels to be well worth while. It might begin with sensibly directed observation and collection out of doors, the sorting and disposal in the classroom of the material so collected, leading to further inquiry and exploration and so to the production of records of educational worth. With older pupils the work might be given a more experimental approach, providing further training in the keeping of records while giving the children a clearer conception of the interdependence of living things and the factors that constitute their environment. Miss Hilda Franks, who followed, emphasized that 70–80 per cent of all children pass through secondary modern schools. The teacher's task, she feels, is to put meaning and value into their lives by fostering in them the love of plants and animals. Interest once aroused will provide the basis for more critical standards and so encourage better ways of living. To her it seems that many social ills might be solved through education based on direct contact with real things.

Field studies at grammar schools were discussed by C. T. Prime and W. H. Dowdeswell. Mr. Prime said that at his school, Whitgift, Croydon, biology specialists in the sixth form can elect to take field studies at advanced level in the examination for the General Certificate of Education. Several do so. One difficulty is that the scripts have to be submitted by the beginning of May; another one is that it is not easy for a young investigator to maintain interest in some selected project throughout a whole year. His procedure is to encourage the boys either to make a general biological survey of some fairly restricted area or to set them the task of making a more intensive study of the biology of one or two species of animals or plants. Problems of identification, which are basic, present difficulties, although in his mind they are not insuperable, for several of the smaller groups of animals and plants provide suitable material.

That young biology investigators should not be expected to take on too much was also the opinion of Mr. Dowdeswell. He has found at Winchester College that the survey of a ten-yard stretch of a local stream is the kind of task that they can manage. In his opinion the essential point is to concentrate on ecological principles, which can be brought out from a wide selection of material. He made a special plea for the study of the soil. It is very variable and it lends itself readily to investigation under school conditions. Experiments on its physical nature and mineral composition are comparatively easy to perform, and there are many biotic factors which can be studied in the field and laboratory bringing out the interrelations within the organic complex.

An account of what she is doing at the Children's Centre, and with the Junior Nature Group, at the British Museum (Natural History) was given by Miss J. Palmer. Altogether, during the past five years about three thousand children have passed through her hands, their ages ranging from eight to seventeen with a heavy preponderance around ten and eleven. Three-quarters of the children were boys and a similar proportion were of grammar school standard. Those that visited the Centre were motivated primarily by the urge to collect specimens. She tried to encourage them to draw, paint and model the living organisms in which they were interested and so train them to observe more carefully. Among young children the urge to collect objects is extremely strong, but after twelve it tends to diminish; her aim is to canalize it in the right scientific direction. She is finding that some of her early members are now anxious to remain at the Centre until they reach seventeen, and they are developing into efficient natural historians. While some of the claims made by the children for what they have observed are fantastic, a few are real additions to scientific knowledge.

Several further points emerged from the open discussions. Among those taking part, difficulties over finding time for field-studies were fully appreciated, although they did not always appear to be so by others. Problems concerned with workrooms and other material facilities are not insoluble, given the right kind of teacher, for in the London area education authorities are said to be sympathetic. Nevertheless, it was generally felt that, as was revealed by a recent report issued by the British Association, the field-work done at schools in Great Britain falls far below what is desirable. The lack of field-work is all the more to be regretted because personal observation has such a favourable influence on what young pupils have to do; in examinations, for example, it is a common experience to find diagrams of plant structure slavishly reproduced from text-books. This brought up the question of training. There was an almost unanimous opinion that university courses in biology are not designed to train teachers for their work, particularly in relation to field studies. Some reform of university courses is essential. Little guidance, too, is forthcoming from the usual type of biology text-book.

As indicated above, the day's proceedings did not do much to help the biology teacher in a grammar school situated in the midst of a thickly built-up area. Certain suggestions were made, but they touched only the fringe of the problem, and it appeared as if the best procedure is to arrange for the pupils to attend short courses at field centres in rural areas. Several speakers commented on the waning of interest in living things among boys and girls in the middle range of grammar schools; they attributed this mainly to the pressure of work in preparing for the General Certificate of Education. No comment, however, was made by teachers on the field studies carried out by young people as a purely voluntary, spare-time activity, particularly during the holidays. Studies of this nature may be fostered by school natural history societies. They bring out certain special educational considerations since they are personal and not directed. They are also the purest source of natural history.

R. Weatherall

POLISH MATHEMATICAL CONGRESS

THE eighth Congress of Polish Mathematicians was held in Warsaw during September 5–12, and was attended, by invitation, by about forty-two mathematicians from outside Poland. There were two British mathematicians present.

The main sections of the Congress were concerned with mathematical logic; the theory of probability and its applications to statistics; modern mathematical methods, especially those of functional analysis and topology and their application to the classical theory; and the role of mathematics in physics and technology. In addition to the main conferences, held mostly in the morning, there were many sections at which short papers were read.

It is interesting to recall the salient features of the Polish school of mathematics. Before the Second World War this school had two main centres, in Warsaw and Lwów respectively. The Warsaw school was occupied largely with the theory of sets and with mathematical logic, and it was in these two branches that it had its greatest achievements. We owe to the Polish set theorists, in particular, some very beautiful theorems on the topology of the plane, such as the extension to certain classes of continuous functions of a form of Weierstrass's theorem on the decomposition of an integral function into primary factors, and Rouché's theorem on the zeros of a holomorphic function inside a closed contour. These extensions have thrown new light on the topological character of these theorems on functions of a complex variable. The Polish school of mathematical logic is perhaps even better known, for the contributions of Polish mathematicians stand out in practically every branch of this subject.

The most outstanding contributions of the Lwów school were in the domain of functional analysis, with which the name of Banach is so intimately associated. It was Banach's work which laid the foundation for so much of modern analysis, and with his death, in the summer of 1945, the world lost a great mathematician. Under his guidance the mathematical life in Lwów, in the years before the War, was very free and friendly, with mathematical discussions taking place frequently in cafés. One of Banach's institutions was what became known as the "Scottish Book"—a book of problems contributed by the Lwów mathematicians, and any others who happened to be visiting Lwów. It was kept in a café frequented by mathematicians, after which it became known. The result was a very interesting collection of mathematical problems. It has survived the War, and a new "Scottish Book" has been started at Wroclaw, where the Lwów Institute has been re-established.

Polish mathematicians suffered enormous losses during the War. Some fifty-four lost their lives, very many in almost unbelievable circumstances, a loss which represented a ratio of about one in four. Immediately after the Nazi invasion those of Jewish descent were declared outlaws. This meant that some were shot almost at once, while others managed to survive in hiding until the summer and autumn of 1943, when they were either shot by the Gestapo or sent to the gas chambers. Saks, Schauder, Auerbach, among very many others, perished in this way. Banach and Mazurkiewicz both died within a few months of liberation. Very many of those who died were young men who had yet to make their full contribution to mathematics, and their loss to Polish mathematics is incalculable. Lives lost cannot be replaced; but every effort has been made during the past eight years to do whatever possible to build up the school again. Generous government grants have enabled the various mathematical institutes to re-establish themselves as research centres. At present they are maintaining three journals of international standing, and several others primarily for circulation in Poland. They are also re-issuing the series of "Mathematical Monographs".

The Congress brought out three things very clearly: first, the remarkable continuity in the Polish school; second, the contributions being made by the younger Polish mathematicians, who have grown up in the years since the War; and third, the desire of all for the better exchange of scientific work. It is true that the work of several of the younger men is already known in Great Britain, but more contact is needed between British and Polish mathematicians. Before the War this was partly achieved as a result of the unfortunate necessity for many Poles to seek posts outside Poland. To-day there are plenty of posts for mathematicians in Poland, and other and happier ways must be found for securing scientific co-operation. It would, for example, be very valuable if some Polish mathematicians were to come to Britain to lecture and hold seminars. Assurances were given at the Congress that for their part they would be very pleased to do so, for they are anxious to develop scientific contact with British mathematicians and would, in particular, welcome suitable papers in their journals.

Polish mathematics has a great tradition, and one peculiarly its own, and it is heartening to know that this famous school is re-establishing itself.

ROYAL GREENWICH OBSERVATORY

ANNUAL REPORT FOR 1952–53

THE annual report of the Astronomer Royal for the period May 1, 1952–April 30, 1953[*], following the scheme of previous reports, deals with three separate sections of the Royal Greenwich Observatory, at Herstmonceux (including H.M. Nautical Almanac Office), Greenwich and Abinger. The recommendation of the Board of Visitors about the old buildings of the Royal Observatory at Greenwich, to which reference was made in the annual report for 1951–52 (see *Nature*, 170, 1111; 1952), has been carried out; the Octagon Room was formally opened by H.R.H. the Duke of Edinburgh on May 8, and is now accessible to the public at regular museum hours. The Time Ball was brought into operation again on October 26 and has since been dropped at 1 p.m. daily, with occasional exceptions. The removal of books from the Library to Herstmonceux was nearing completion at the time of the visitation, and some of the shelving had also been moved to the huts at Herstmonceux, to be used for storing some of the contents of the Greenwich Record Rooms.

Large variations in the voltage of the mains electricity supply at Abinger have been responsible for considerable inconvenience to the operational work of the Time Service and, pending modification in the supply arrangements, a static balancer has been temporarily installed. At Herstmonceux there has been satisfactory progress in various structural alterations, lighting, etc., and the foundations for the control building for the photographic zenith tube have been completed. Contracts have been let for the manufacture and erection of the buildings to house the Cooke reversible transit circle, the photographic zenith tube, and the Bamberg small transit; the expected completion dates of these buildings will be greatly delayed, but it is hoped that they will all be erected by the end of the year.

The Ordnance Survey is to fix a datum point in a position that has been selected to the south of the site for the Isaac Newton telescope. The position of the base plate of the Cooke reversible transit circle, when it has been placed in position and before the erection of the walls of its housing, will be determined relative to the datum point. An accurate geodetic connexion between the Cooke reversible transit circle at Herstmonceux and the Airy transit circle at Greenwich can thus be derived. It is satisfactory to know that the working drawings for the equatorial group of instruments have been completed and that it may be possible before the end of the summer to accept tenders for the steel work.

It is only possible in this limited space to refer to a few matters of outstanding interest or importance. Among the former, attention may be directed to the fact that facilities have been granted at Herstmonceux to members of the Atomic Energy Research Establishment, Harwell, for the investigation of the recently discovered light flashes in the sky. It is believed that these short bursts of light are Čerenkov radiation from cosmic rays in the atmosphere. Observations with a photoelectric recording unit installed in the solar dome are already being made by members of the Establishment and of the Observatory; but during the summer months these tests are discontinued owing to the short period of total darkness during the nights.

Experiments have been made at the outside broadcast headquarters of the B.B.C. Television Service at Wembley on televising the disk of Jupiter, using a 14-in. reflecting telescope fed by a coelostat. With the very sensitive photocathodes used in modern television cameras, promising results were obtained, and it was proposed to attach such a camera to the Yapp reflector during the autumn to show Jupiter in short astronomical programmes.

As foreshadowed in last year's report, a substantial reduction in the staff of the Nautical Almanac Office has been possible through the concentration of routine computing on the punched-card machines. This reduction has been effected by leaving vacancies unfilled and also by transferring some members of the Nautical Almanac staff to other departments of the Observatory. In the account of the work of the machines, which is given in the report, the large amount of work that has been accomplished is summarized, and, speaking of one particular undertaking, the report says: "This last job has proved peculiarly suitable for punched-card methods . . .; it is difficult to see how this work, involving the formation, checking, and summation in groups, of some four million terms, could otherwise have been done, except on an electronic machine".

It is satisfactory to notice that the report ends with an optimistic outlook—different from that of some of the reports issued in recent years—and it is hoped that the removal of the Observatory to Herstmonceux will be substantially complete by the end of 1956.

---

RESEARCH AND DEVELOPMENT IN BRITISH COLONIAL TERRITORIES

THE now customary annual review of events and developments in British Colonial and Protected Territories is provided in the report entitled "The Colonial Territories 1952–53"[*]; the survey is of exceptional interest this year on three counts. First, it provides the man of science with the background against which the subsequent report, "Colonial Research 1952–53", will appropriately be considered. The recent statement in the House of Commons by the Colonial Secretary, Mr. Oliver Lyttelton, regarding the forthcoming legislation on Colonial development and welfare funds gives unusual interest to this background for Colonial development in general as well as for Colonial research. It is also of interest in the same way in relation to the proposals for educational development in Africa, alike for suggestions that have come from the report on African education sponsored by the Nuffield Foundation and the Colonial Office or from the Commission on Higher Education for Africans in Central Africa. Moreover, while the review of constitutional and administrative developments is of topical interest in so far as it concerns federation in Central Africa, such political developments cannot be ignored by those concerned with or interested in higher education, for example, as has already become apparent in regard to the principal recommendation of the Carr-Saunders Commission.

---

[*] Colonial Office. The Colonial Territories 1952–53. (Cmd. 8856.) Pp. ix+157. (London: H.M.S.O., 1953.) 5s. net.

To the man of science the review is chiefly of interest in that it provides the proper perspective for regarding developments with which he is more intimately concerned. The general survey, which forms Part 1 of the report, brings out the essential relation between the political evolution of the territories and their technical, scientific, medical and social development, and it should contribute both to a wider realization of the extent to which responsibility for self-government in these areas has already been devolved and to the understanding on which responsible criticism, whether in the political or in the technical field, must be based. While prominence is given to constitutional changes—for example, in British Guiana, in Nigeria and in Central Africa—the emphasis of the review lies this year as much on advances in education as on economic matters. The operations of the Colonial Development Corporation and the Volta River aluminium scheme are seen in perspective and also the dependence of the Colonial territories on the continued provision of the funds which have been provided under the Colonial Development and Welfare Acts ; but it is increasingly clear that the crucial factor in political and in economic development is education.

Except Central Africa, all the main Colonial regions now have local universities, and there are 3,464 students enrolled in the seven university institutions, compared with 3,417 in the previous year, while the number of Colonial students in the United Kingdom and Republic of Ireland has risen from 5,150 to 6,300, of which 1,443 hold scholarships. The £6 million originally allocated for higher education under the 1945 Act has been fully committed, but an additional allocation from funds available under the 1950 Act is making possible the completion of some of the capital programmes which had to be seriously curtailed because of rising prices, and also the financing of some of the most urgently needed new developments at existing institutions. Besides a further £750,000 towards the cost of the new teaching hospital, the Nigerian Government has given £1·5 million to University College, Ibadan, as an expendable endowment over fifteen years, and £300,000 for capital expenditure. The Gold Coast Government is unable at present to embark on the establishment of a medical school at the University College of the Gold Coast. A welcome development at Makerere College, the University College of East Africa, has been the substantial proportion of students completing their preliminary science training whose first preference is the agricultural course. A warm tribute is paid in the report to the help given to these young university colleges by the University of London.

In higher technical education the Gold Coast College of Technology, Science and Arts at Kumasi was able to admit 450 students to courses starting late in 1952 and in January 1953. The Nigerian College of Arts, Science and Technology was established in May as an autonomous institution with branches at Ibadan, Zaria and Enugu, with the main branch at Zaria, and the original allocation of Colonial Development and Welfare Funds was increased to £600,000. The appointment of a principal designate of the Government Technical Institute enabled the Sierra Leone Government and the Fourah Bay College to co-ordinate plans for the development of technical education generally. Tribute is paid to the Nuffield Foundation for its help in financing the survey of education in West and in East and Central Africa by two study groups, the reports of which were discussed at a subsequent conference in Cambridge, and attention is directed to signs of increasing recognition of the importance of the education of girls : for example, the first government boarding school for girls in Somaliland was opened during the year, and in Hong Kong a new technical school for girls ; the first Fijian girls have been admitted to the Central Medical School for the Pacific ; and in Mauritius the foundations have been laid of the new building for Queen Elizabeth College, the government girls' secondary school.

The review notes that for the first time for many years health service establishments are up to strength in most territories. The expansion is not always equal to the need, and hospitals, health centres and infant and welfare centres are under heavy pressure. At Singapore, for example, the annual out-patient attendance approaches six hundred thousand compared with ninety thousand before the Second World War. The increased demand for curative services, which is an index of the confidence that has been won during recent years and a contributory factor to the striking improvement in health statistics, involves problems for the Colonial governments in keeping a reasonable balance between curative and preventive services. Increased industrialization, with the corollary of migration of labour and the creation of new urban centres, has required careful planning of health services to avert any serious complication, and a spectacular instance has been the eradication for three months of the fly *Simulium damnosum*, the larvæ of which carry the filarial disease known as onchocerciasis, by applying lethal concentrations of DDT to its breeding places over a forty-mile stretch of the Nile. A preliminary entomological survey of the Volta River area has provided the Department of Health of the Gold Coast with much of the information required to minimize dangers to health when the scheme begins to operate. Following the eradication of malaria from Cyprus, the disease has now been almost eliminated in Mauritius, virtually from Singapore, and notable progress is reported in British Guiana and Malaya. The sulphone drugs now in universal use in the Colonial territories hold promise of ultimately eradicating this disease also : of thirty thousand patients receiving treatment in Eastern Nigeria, six thousand were discharged as free of symptoms in 1952. Mastery is also being gained over trypanosomiasis : in Nigeria, while during 1931–40 more than three million people were examined and 395,554 cases treated, during 1946–52, of five and a half millions examined only 73,585 needed treatment, and during 1952 only seven thousand were treated, compared with ninety thousand at the peak. While the disease remains endemic in East and Central Africa, it is considered unlikely that serious epidemics will ever again become established. The outbreak of yellow fever in Nigeria during November 1951 was completely under control early in 1952, and no further cases have been reported there or in Sierra Leone or the Gambia. The last outbreak in the Caribbean area was in 1921 in British Honduras, and the mosquito which carries the disease has been eradicated from Corozal, although still present, in limited numbers, in Belize.

All this has demanded a continued high rate of recruitment to the Colonial Medical Service from the

United Kingdom and other Commonwealth countries, and 147 doctors were appointed in 1952, while there is a steadily increasing number of medical officers of local origin, particularly in the Far East, West Africa, the West Indies, Cyprus and Mauritius. Whereas on January 31, 1953, 638 Colonial students were reading medicine in the United Kingdom and Eire, young men qualifying locally still seemed to prefer private practice to entering government service. An increase in the number of specialist posts has been noticeable, and especially in the fields of radiology, anæsthetics, pathology and psychiatry it has been difficult to fill such posts by recruitment from the United Kingdom. In this section of the report emphasis is once again laid on the dependence of any solid expansion of the health services on the adequate training of sufficient numbers of auxiliary technical, clinical and nursing staff.

The scale of assistance sought by the Colonial territories under the Expanded Programme of United Nations Technical Assistance increased, and among the requests noted are those from the following countries: Tanganyika, three geologists for a mineral exploration team; the Federation of Malaya, an expert in the rehabilitation of the blind, for the training of radio-technicians and for an aero-magnetic survey; Jamaica, a palæontologist; British Guiana, a hydro-electric expert; British Honduras, a rice expert; Kenya, a pineapple canning expert; and the Gold Coast, an expert in mass-education rural training centres. Considerable use is being made by the Colonial territories of the fellowship facilities offered by the United Nations and the Specialized Agencies, and eighty-one such fellowships and scholarships are now held.

The expenditure of £14 million on development and welfare schemes and on research schemes was approximately the same as during 1951–52; but although research schemes are specifically excepted from the statutory time limit, the available funds are already almost fully committed, and it is pointed out that the position will soon be reached when no new long-term projects can be undertaken, in the absence of further funds. The progress in research is reported fully in the subsequent report "Colonial Research, 1952–53", and it will suffice here to note that the West African Governments are considering proposals for the establishment of a West African Agricultural Research Advisory Committee with a permanent secretariat, that the Clove Research Unit in Zanzibar has established the causes of slow-decline, die-back and sudden-death in clove trees, and the Zanzibar Government is planning experiments to control the two fungi which are responsible for these diseases. The recruitment of field staff for geodetic and topographical surveys in the Colonial territories did not keep pace with resignations or transfers, but prospects of recruitment of field surveyors and other technical staff are now much better, and the total staff is expected to be increased by more than fifty during 1953–54. The overseas scientific staff of the Colonial Geological Surveys increased from 180 to 190 during 1952, and the universities continued to show their interest in the geology and natural resources of the Colonial territories.

Besides the expenditure from Colonial Development and Welfare Funds (which included replenishment of the central allocation for broadcasting by £250,000 to complete the programme of capital equipment, and of that for Students' Welfare by £284,000 to permit continuance of existing services to March 31, 1956), approximately £25,250,000 was expended on the Colonial territories from the Vote for Colonial and Middle-Eastern Services in 1952–53, part of this being grants for the repair of damage and for rehabilitation or reconstruction in the West Indies caused by earthquake, hurricane, flood or fire. Although the large financial contribution which the United Kingdom is making to Colonial development and welfare is fully displayed in this survey, it is equally pointed out how such developments depend upon closer co-operation and understanding between the United Kingdom Government and those of the Colonial territories, between the several departments concerned (for example, eradication of the tsetse-fly has required the co-operation of every field department of the Colonial governments), between local and overseas staff and between government and the people served. The educational developments recorded in this report are clearly contributing both to the supply of leaders able to fulfil their new and growing responsibilities with the goodwill and judgment that the present leaders, on the Gold Coast and elsewhere, are manifestly striving to show, and also to the training of a community able and willing to co-operate. The existence of a like goodwill on the part of the United Kingdom is also recorded, which joined to imagination could well make partnership a reality and no more a pious sentiment.

URIDYL TRANSFERASES AND THE FORMATION OF URIDINE TRIPHOSPHATE*

Enzymic Production of Uridine Triphosphate: Uridine Diphosphoglucose Pyrophosphorolysis

In the present communication we wish to describe a hitherto unrecognized pathway by which uridine triphosphate can be formed. We have previously reported[1] that dialysed yeast maceration juice contains an enzyme which in the presence of uridine diphosphoglucose[2] brings about an incorporation of inorganic pyrophosphate labelled with phosphorus-32 into a uridine nucleotide with simultaneous splitting-off of glucose-1-phosphate. This enzyme, which we called uridine diphosphoglucose pyrophosphorylase[3] (in analogy with other pyrophosphorylases), does not in any detectable way attack other known uridine diphosphoglycosyl compounds. However, it has been shown recently[4] that a suspension of rat liver nuclei pyrophosphorylates uridine diphosphate-N-acetylglucosamine as well as uridine diphosphoglucose.

The specific uridine diphosphoglucose pyrophosphorylase is present in *Zwischenferment* preparations[3,4], particularly in the fraction precipitated by between 60 and 70 per cent saturated ammonium sulphate. If phosphoglucomutase and triphosphopyridine nucleotide are added, the liberation of glucose-1-phosphate from uridine diphosphoglucose can be followed[3] at 340 mμ. For each mole of pyrophosphate incorporated into the nucleotide, one mole of α-glucose-1-phosphate is liberated. A demonstration

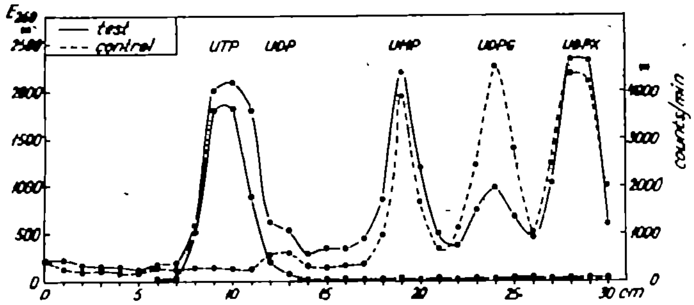

Fig. 1. Paper chromatogram of norite eluate from uridine diphosphoglucose pyrophosphorylase digest

Abscissa: distance from starting line in cm.; ordinate: extinction × 10^3 at 260 mμ.

Reaction mixture: 0·2 μmol. uridine diphosphoglucose; 2 μmol. inorganic pyrophosphate (8 × 10^4 counts/min.); 50 μl. *Zwischenferment* (8 mgm./ml.); 3 ml. *M*/10 *tris*-hydroxymethyl amino methane hydrochloride, *p*H 8·0; *M*/100 magnesium chloride. Control mixture: same without pyrophosphate.

After 45 min. incubation the digests were acidified, adsorbed on norite and eluted with 50 per cent ethanol. Chromatographed 44 hr. in neutral solvent (ref. 9). Chromatogram scanned in the Beckman spectrophotometer at 260 mμ and in the Geiger counter

and purification of the new nucleotide, which was suspected to be uridine triphosphate, can be carried out on a microscale as described in Fig. 1. The nucleotide can also be isolated from a 'Dowex Cl' column by elution with 0·2 *M* sodium chloride in 0·01 *M* hydrochloric acid; other uridine compounds, including uridine diphosphate, can be eluted with 0·1 *M* sodium chloride in 0·01 *M* hydrochloric acid. The molar ratio of uracil, estimated at 260 mμ, to radioactive pyrophosphate was found to be 1·18 (calculated for uridine triphosphate, 1·00); total phosphorus/uracil was 2·7 (calculated for uridine triphosphate, 3·0).

Uridine triphosphate is active in two reactions in which the diphosphate was completely inactive. The first reaction is the phosphorylation of glucose[7] via adenosine diphosphate, which is described in a separate communication[8]. This reaction, in which uridine triphosphate and adenosine diphosphate react to form adenosine triphosphate, which then phosphorylates glucose, has been used to assay uridine triphosphate. It has then been possible to determine that an hour's exposure to 0·01 *M* mineral acid at 100° C. brings about a 50 per cent hydrolysis of uridine triphosphate.

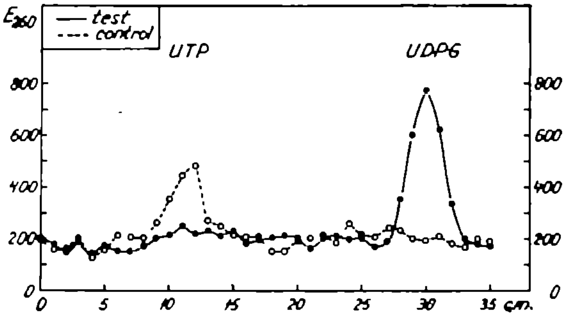

Fig. 2. Paper chromatogram of norite eluate from uridine triphosphate pyrophosphorylase digest

Abscissa. distance from starting line in cm.; ordinate: extinction × 10^3 at 260 mμ.

Reaction mixture · 0·2 μmol. uridine triphosphate; 10 μmol. α-glucose-1-phosphate; 100 μl inorganic pyrophosphatase, 50 μl. *Zwischenferment* (3 mgm./ml.); 1 ml *M*/10 *tris*-hydroxymethyl aminomethane hydrochloride, *p*H 8 0, *M*/100 magnesium chloride. Control mixture: same without α-glucose-1-phosphate

After 50 min. incubation, the digests were acidified, adsorbed on norite and eluted with 50 per cent ethanol. Chromatographed 44 hr. in neutral solvent (ref. 9). Chromatogram scanned in the Beckman spectrophotometer at 260 mμ.

In the norite filtrates, inorganic phosphate was precipitated as magnesium–ammonia salt, washed with dilute ammonia and dissolved in 150 μl. 0·2 *M* sulphuric acid. Counting the samples in the Geiger counter gave the following results, expressed as counts per min.· control, 186; test, 3,660

In the second reaction, uridine triphosphate as well as uridine diphosphoglucose act as uridyl donors, that is, the so-called uridine diphosphoglucose pyrophosphorylase could also be called a uridyl transferase and the action could be formulated as follows:

$$\text{UDPGlucose} + \text{pyrophosphate} \rightleftharpoons \text{UTP} + \alpha\text{-glucose-1-phosphate.}$$

The reaction from left to right has been described briefly[1]. The reverse reaction, that is, formation of uridine diphosphoglucose from uridine triphosphate and α-glucose-1-phosphate, has been followed, using uridine triphosphate labelled with phosphorus-32 (uridine - P - ^{32}P - ^{32}P) and converting the inorganic pyrophosphate generated to orthophosphate by means of a specific pyrophosphatase for inorganic pyrophosphate. The results of a typical experiment are illustrated in Fig. 2.

'Uridyl'

Fig. 3. Uridine diphosphoglucose

In accordance with observations made on the pyrophosphorolysis of uridine diphosphoglucose, the reaction can therefore be expressed according to the reaction written above. The enzyme catalysing this process in both directions could consequently be classified as a uridyl transferase with inorganic pyrophosphate or α-glucose-1-phosphate as uridyl acceptor. The location of fission by the transfer reaction can be illustrated by the formula shown in Fig. 3. The following communication illustrates that there exists at least one more acceptor for this type of reaction: α-galactose-1-phosphate.

Uridyl Transferases and the Formation of Uridine Diphosphogalactose

Leloir and co-workers have shown that uridine diphosphoglucose is the coenzyme of the enzymic conversion of α-galactose-1-phosphate to α-glucose-1-phosphate in galactose-adapted yeast, *Saccharomyces fragilis*[1]. Leloir has demonstrated directly the presence of an inversion enzyme (*Galactowaldenase*) in *S. fragilis* which catalyses the equilibrium uridine diphosphoglucose $\rightleftarrows$ uridine diphosphogalactose in which 75 per cent exists in the glucosyl form and 25 per cent in the galactosyl form[2].

We have found two other reactions which result in the formation of uridine diphosphogalactose. The first reaction is between uridine triphosphate and α-galactose-1-phosphate and takes place in the presence of a dialysed extract of *S. fragilis*:

UTP + α-galactose-1-phosphate $\rightleftarrows$
UDPGalactose + α-glucose-1-phosphate. (1)

The second reaction, which can be demonstrated in extracts of *S. fragilis* which have lost the inversion enzyme by standing, is a direct exchange between uridine diphosphoglucose and α-galactose-1-phosphate:

UDPGlucose + α-galactose-1-phosphate $\rightleftarrows$
UDPGalactose + α-glucose-1-phosphate. (2)

In the presence of phosphoglucomutase, *Zwischenferment* and triphosphopyridine nucleotide, uridine diphosphoglucose is consumed stoichiometrically and the uridine diphosphoglycosyl compound formed does not react when incubated with uridine diphosphoglucose pyrophosphorylase, inorganic pyrophosphate, *Zwischenferment* and triphosphopyridine nucleotide[3].

That this reaction is a direct exchange incorporation (Leloir's first equation[2]) and involves no pyrophosphorolytic mechanism is emphasized by the fact that the reaction proceeds in the absence of inorganic pyrophosphate and even in the presence of inorganic pyrophosphatase. Reactions (1) and (2) can be demonstrated when to a fresh, dialysed extract of *S. fragilis* is added uridine triphosphate, α-galactose-1-phosphate and triphosphopyridine nucleotide. Under these conditions, an amount of glucose-6-phosphate (detected by the measurement of reduction of triphosphopyridine nucleotide at 340 mμ) is formed which is at least three times the amount of uridine triphosphate added (Fig. 1). This is due to the following sequence of reactions, which is catalysed by enzymes all present in dialysed *S. fragilis* extracts:

(*a*) UTP + galactose-1-phosphate $\rightarrow$ UDPGalactose + pyrophosphate
(*b*) (Pyrophosphate + H_2O $\rightarrow$ 2 orthophosphate)
(*c*) UDPGalactose $\rightarrow$ UDPGlucose
(*d*) UDPGlucose + galactose-1-phosphate $\rightarrow$ UDPGalactose + glucose-1-phosphate
(*e*) Glucose-1-phosphate $\rightarrow$ glucose-6-phosphate
(*f*) Glucose-6-phosphate + TPN^+ + H_2O $\rightarrow$ 6-phosphogluconic acid + TPNH + H^+

Incubation of the *S. fragilis* extract with each component separately does not yield glucose-6-phosphate.

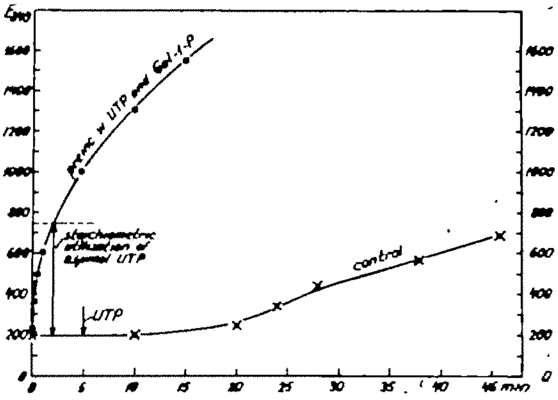

Fig. 1. Spectrophotometric analysis (reduction of triphosphopyridine nucleotide) of glucose-6-phosphate from uridine triphosphate and α-galactose-1-phosphate in *S. fragilis* extracts

Abscissa: time in minutes; ordinate: extinction × 10^3 at 340 mμ.

Reaction mixture: 0·1 μmol. uridine triphosphate, 0·6 μmol. α-galactose-1-phosphate (by courtesy of Prof. L. Leloir and Dr. J. Reissig, Instituto de Investigaciones Bioquímicas, Fundación Campomar, Buenos Aires; barium salt, subjected to reprecipitation with ethanol, acid-labile phosphate estimated), 50 μl. dialysed *S. fragilis* extract (approx. 25 μgm. protein), 500 μl. 0·1 *M* tris-hydroxymethyl aminomethane hydrochloride, *p*H 8·0, *M*/100 magnesium chloride.

Control mixture: same, without uridine triphosphate.

After 30 min. incubation, excess of triphosphopyridine nucleotide was added (time zero on the graph). At 5 min., 0·1 μmol. uridine triphosphate was added to the control

The fact that not only uridine diphosphoglucose and uridine diphosphogalactose but also uridine tri- and even di-phosphate + adenosine triphosphate[4] can act as inversion coenzyme (*co-Waldenase*) makes the *co-Waldenase* assay less specific for certain purposes in which a biological identification of uridine diphosphoglucose, for example, is wanted. For such bio-assays the specific uridine diphosphoglucose pyrophosphorylase in *Zwischenferment*[3] seems, for the time being at least, the most suitable tool.

Uridine diphosphogalactose can thus apparently be formed in three different ways: (i) enzymic inversion of uridine diphosphoglucose (catalysed by galactowaldenase); (ii) enzymic transfer of uridyl from glucose-1-phosphate to galactose-1-phosphate; and (iii) enzymic transfer of uridyl from pyrophosphate to galactose-1-phosphate.

Pyrophosphorolysis of Uridine Diphosphoglucose and 'UDPX' by a Rat Liver Nuclear Fraction

A uridine diphosphoglycosyl compound, chromatographically identical with the 'UDPX' factor obtained by Paladini and Leloir[1] from yeast, has been isolated from rat liver as indicated in the accompanying scheme [p. 1039]. The 80 per cent ethanol insoluble barium fraction so isolated contained approximately 50 per cent adenosine monophosphate, 20 per cent uridine monophosphate and 30 per cent 'UDPX' as determined chromatographically. Separation of the pure 'UDPX' was achieved by paper chromatography using the ethanol–ammonium acetate solvent (*p*H 7) of Paladini and Leloir[1].

In common with the 'UDPX' obtained from yeast, that from rat liver does not undergo pyrophosphorolysis to uridine triphosphate in the presence of

inorganic pyrophosphate labelled with phosphorus-32 and *Zwischenferment* preparations[2]. However, in the presence of a rat liver nuclear fraction isolated by the method of Hogeboom and Schneider[3], the 'UDPX' of rat liver incorporates phosphorus-32 pyrophosphate with the formation of a uridine nucleotide. The latter has been identified as uridine triphosphate by the chromatographic methods described by Munch-Petersen *et al.*[2].

Uridine diphosphoglucose obtained from yeast also undergoes pyrophosphorolysis to uridine triphosphate in the presence of the rat liver nuclear fraction; in this instance, the speed of reaction appears to be greater than in the case of the 'UDPX' of rat liver.

Further investigations are in progress to determine the quantitative aspects of the localization of this pyrophosphorylase in cell fractions.

VANADIUM AS AN ESSENTIAL ELEMENT FOR GREEN PLANTS

By PROF. DANIEL I. ARNON and GUNILLA WESSEL

Department of Plant Nutrition, University of California, Berkeley

THE use of the green alga, *Scenedesmus obliquus*, for the study of the micronutrient requirements of green plants has yielded evidence that vanadium is essential. The identification of this new micronutrient for the growth of algae resulted from experiments concerned with their iron nutrition. When *Scenedesmus* was grown in a purified basic nutrient solution supplemented with all the known essential micronutrients for green plants, boron, manganese, copper, zinc and molybdenum (the *A5* solution[1]), a marked increase in growth was observed with increasing iron concentrations. Since the iron salts in these experiments were not purified, it seemed possible that the increase in growth at high iron concentrations resulted from some unknown essential micronutrient commonly present as an impurity in iron salts.

This supposition was tested by growing *Scenedesmus* at three levels of iron supply: 0·1, 1·0 and 4·0 mgm. of iron per litre of nutrient solution. Purified ferric chloride[2] was used as a source of iron. To one series of cultures was added a supplementary solution (*B*3) which provided 10 μgm. per litre each of cobalt, nickel and vanadium, three elements which were likely to have been among those removed by the purification of ferric chloride. The results are shown in Fig. 1. In this, as in all subsequent experiments, growth as measured by dry weight (shown here), and by the additional criteria of fresh weight (packed cell volume), cell count and chlorophyll content, gave concordant results.

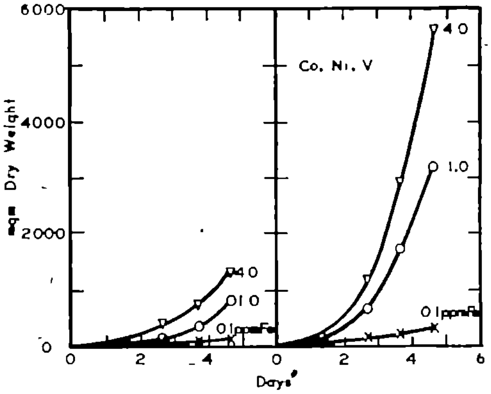

Fig. 1. Effect of a mixture of cobalt, nickel and vanadium (*B*3 solution) on the growth of *Scenedesmus obliquus* in a purified medium at three levels of iron: 0·1, 1 0 and 4·0 p.p.m. Left: growth (mgm. dry weight per litre of nutrient solution) without the addition of the *B*3 solution. Right: effect of adding the *B*3 solution. The *B*3 solution supplied 10 μgm. per litre of cobalt, nickel and vanadium as cobalt nitrate, nickel sulphate and ammonium vanadate, respectively

0·1 mgm. iron per litre was clearly insufficient for growth regardless of the addition of the supplementary solution *B*3. However, at 1·0 and 4·0 mgm. iron, a marked increase in growth has resulted from the addition of a mixture of cobalt, nickel and vanadium. At iron concentrations adequate for vigorous growth, that is, 1 mgm. or more per litre, the growth of algae was distinctly limited by the insufficiency of at least one of the three elements in the *B*3 solution. Fig. 2 shows that vanadium was the effective element. The addition of cobalt or nickel gave no measurable increase in growth. In another experiment, four parallel cultures were grown in a purified medium without the addition of vanadium. On the fourth day when a deficiency was apparent, the addition of vanadium to two of the cultures was followed by a sharp increase in growth (Fig. 3).

Of sixteen other elements, titanium, chromium, tungsten, aluminium, arsenic, cadmium, strontium, mercury, lead, lithium, rubidium, bromine, iodine, fluorine, selenium and beryllium (the remaining elements in the *B*6 and *C*13 solutions[2]), added to the vanadium-deficient cultures, none was found

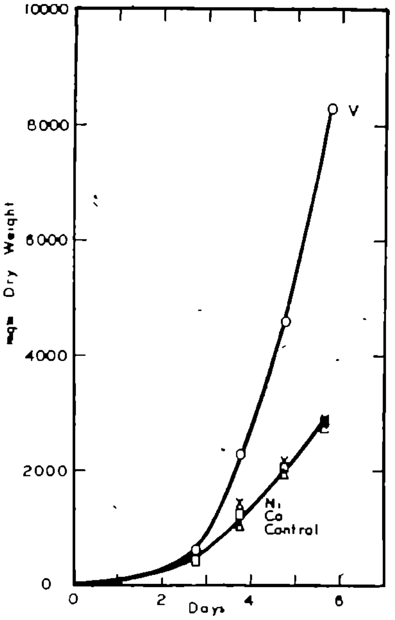

Fig. 2. -Effect of nickel, cobalt and vanadium (supplied from sources and in amounts given in legend to Fig. 1) on the growth of *Scenedesmus obliquus* (mgm. dry weight per litre of nutrient solution). 1 p.p.m. iron was supplied as ferric chloride

capable of substituting for vanadium. This specificity[9] of vanadium is regarded as supporting its proposed status as an essential element for green plants. Although we know of no evidence at present for the indispensability of vanadium for other plants, it appears likely that vanadium, like other micronutrients the essentiality of which was at first rigidly established for only one plant species[4], will be shown to be generally required by green plants. Bertrand[5] has already found that vanadium is widely distributed in plants. Of sixty-two species analysed by him all contained this element.

A biological role for vanadium is not confined to green plants. Bertrand[6] has concluded that vanadium is an essential micronutrient for *Aspergillus niger*. The occurrence of a vanadium pigment in Tunicates has long been recognized (cf. ref. 7). It is also of special interest that vanadium can replace molybdenum as a catalyst in nitrogen fixation by *Azotobacter* and *Clostridium*[8], although there is no evidence that vanadium is required in the presence of molybdenum. In our experiments, the requirement for vanadium was observed in the presence of an adequate supply of molybdenum and, conversely, in the investigation of the essentiality of molybdenum for *Scenedesmus*[9] there was no evidence for the replacement of molybdenum by vanadium. Other observations also point to specific effects of vanadium as distinct from molybdenum. The minimum molybdenum requirement of *Scenedesmus* was found to be low: approximately 1,200 atoms of molybdenum to a single cell. There was no improvement in growth at concentrations greater than 0·1 μgm. molybdenum per litre of nutrient solution[9]. With vanadium, increasing initial rates of growth were observed with concentrations up to 100 μgm. vanadium per litre. Under conditions of molybdenum-deficiency *Scenedesmus* showed a marked decline in chlorophyll concentration, whereas with the vanadium-deficient algae the decline in chlorophyll content was much less pronounced.

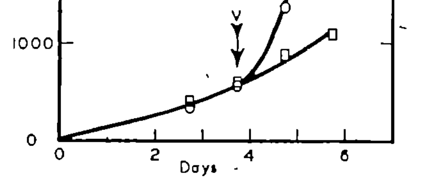

Fig. 3. Effect of adding vanadium on the growth of vanadium-deficient *Scenedesmus obliquus* cultures. At the time indicated by arrow, 20 μgm. vanadium (as ammonium vanadate) was added per litre of nutrient solution. Growth is expressed in milligrams dry weight per litre of nutrient solution. 1 p.p.m. iron was supplied as ferric chloride

The algae were grown in a basic nutrient solution of the following composition: 0·020 *M* potassium nitrate, 0·002 *M* potassium dihydrogen phosphate, 0·001 *M* magnesium sulphate, 0·0005 *M* calcium nitrate, supplemented with the *A*4 solution[1] (boron, manganese, zinc and copper). Molybdenum was added at a concentration of 0·1 μgm. per litre, which was previously found adequate for growth of this organism under the same conditions[9]. Iron was supplied in variable amounts as ferric chloride. The basic nutrient solution salts were individually purified by co-precipitation with copper sulphide[10]. Ferric chloride was separated from other metal impurities by extraction with ethyl ether in hydrochloric acid[2]. 'Pyrex' glass-distilled water was used throughout in making up nutrient media. The initial *p*H of the solution was adjusted to 6·7 with potassium hydroxide.

The algae were grown in 1-litre 'Pyrex' Roux culture bottles containing 240 ml. of nutrient solution inoculated at the rate of 10^8 cells per litre. The bottles were laid flat and shaken continuously in a horizontal plane on a 'pendulum type' shaker[3]. Continuous illumination from below was provided by a bank of fluorescent lights giving an incident light intensity of 1,000 foot-candles. A mixture of air and approximately 5 per cent carbon dioxide was continuously supplied to the nutrient solution. Full details of this investigation will be presented elsewhere.

We wish to thank Drs. Robert Emerson and R. C. Fuller for cultures of *Scenedesmus*, and Dr. C. M. Johnson for a preparation of purified ferric chloride.

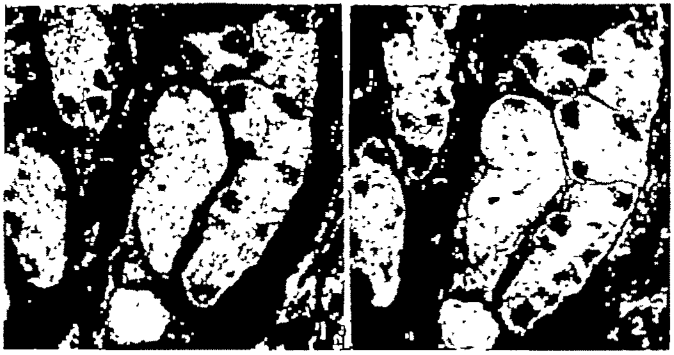
A Comparison between the X-Ray Absorption and Optical Interference Methods for the Mass Determination of Biological Structures

In histo- and cyto-chemistry there has been a trend towards the development of specific techniques for the identification and quantitative determination of biologically important compounds. However, there is a great need for a completely non-specific method which records the total mass of cell structures irrespective of the chemical nature of their constituents. Two such methods have been developed in recent years. One is based on the absorption of very soft X-rays by the biological tissue[1]. As the samples are investigated *in vacuo*, the total dry mass is obtained. The other method[2,3] makes use of measurements of cell refractivity or optical path-length, which is related to the total mass of substances other than water, that is, the dry mass. Measurement of optical path-differences can be made by means of interference microscopy, and the application of the Dyson interference microscope[4] in quantitative cytochemistry has been discussed[5].



Section of dog gastric mucosa. (1) X-ray absorption image; (2) interference contrast

We have compared the results obtained by these two methods when applied to a variety of biological structures. Visual comparison between the images in X-ray and interference contrast (using the Dyson microscope made by Cooke, Troughton and Simms) revealed a similarity in the distribution of the total dry substance. This is illustrated in the comparative photomicrographs (Figs. 1 and 2) of a section of dog gastric mucosa, 3 μ thick. The interference picture (Fig. 2) was taken with an even illumination over the field, and under these conditions it may be shown that the distribution of light intensity can run approximately parallel with the dry mass per unit area. The parietal cells with low mass per unit area and the chief cells with relatively high mass per unit area appear dark and light respectively in both types of contrast. A similar correspondence between the distribution of dry substance was found in all types of tissues examined, for example, muscle fibres, blood cells, nerve cells and nerve fibres. The mass variation in intact bone as revealed by X-rays of shorter wave-lengths was also in agreement with that shown by interferometry.

Table 1

Material		μμgm./μ²	
		X-rays	Interference
Skin (human)			
Str. corneum point	1	2·7	2·5
	2	3·0	2·9
	3	3·2	2·9
	4	3·0	2·9
Str. mucosum	5	1·3	1·4
	6	0·9	1·0
	7	1·0	1·2
Aorta 1 (rabbit)		1·7–1·8	1·3
„ 2 „		1·7	1·2
Gastric mucosa (dog)			
Parietal cells		0·8–1·0	0·8–1·3
Chief cells		2·3–2·6	2·2–2·8
Ventral horn cells (dog)	1	1·3	1·1
	2	1·5	1·3
	3	1·6	1·6
	4	1·2	1·3
Thyroid follicles (rat)	1	1·4	1·5
	2	1·4	1·4
	3	1·6	2·0
	4	1·8	1·7
	5	1·6	1·7
	6	1·7	1·9
	7	1·4	1·9
	8	1·5	1·9

Table 1 contains some of the quantitative measurements made on a variety of materials using the two techniques, and it shows that there is a fairly good agreement. The above results were obtained with structures of varying degrees of inhomogeneity. On homogeneous retinal rods from the frog, the concentrations of dry substance obtained by X-rays and interferometry were 0·41 and 0·39 μμgm./μ² respectively.

The relative features of the two methods may be summarized as follows. The structural resolving power of the present X-ray method is about 1 μ, whereas the interferometric technique has the full resolving power of the light microscope. A difference in mass per unit area of about 0·1 μμgm./μ² can just be detected by the X-ray technique, whereas the sensitivity of the interferometric method may well be an order of magnitude greater.

However, the particular advantage of the interference microscope is that it may be used for following the changes in dry mass of individual living and undamaged cells. In the X-ray method, fixation artefacts are minimized by the use of freeze-drying. It is difficult to state precisely the accuracy of the quantitative measurements obtained by each of the two methods, as it depends on technical procedure and the nature of the biological material. A full account of this work will be published elsewhere.

A New Method for the Quantitative Determination of Chloride in Plant Material

USING the well-known property of a silver – silver chloride electrode of behaving both as a silver electrode and a chlorine electrode, it appeared possible to develop a new quantitative determination of chloride in aqueous solutions.

Two silver electrodes, coated electrolytically with silver chloride, dip into a solution containing chloride which is titrated with silver nitrate. A small potential difference (about 100 mV. direct current) is set up between the electrodes, the current flowing being measured with a sensitive galvanometer (Fig. 1).

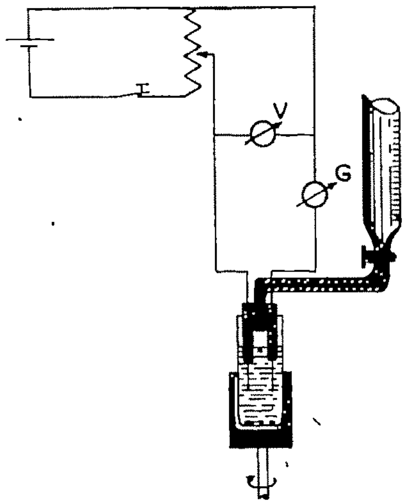

Fig. 1

So long as the chloride concentration is greater than the square root of the solubility product of silver chloride, a current flows, accompanied by the reactions:

Cathode	Anode
$AgCl + e \rightarrow Ag + Cl'$	$Ag + Cl' \rightarrow AgCl + e$

This current is limited by the chloride concentration, so it decreases during titration until it reaches a minimum value at the end point, where $[Ag^{\cdot}] = [Cl'] = \sqrt{L_{AgCl}}$ (L = solubility product).

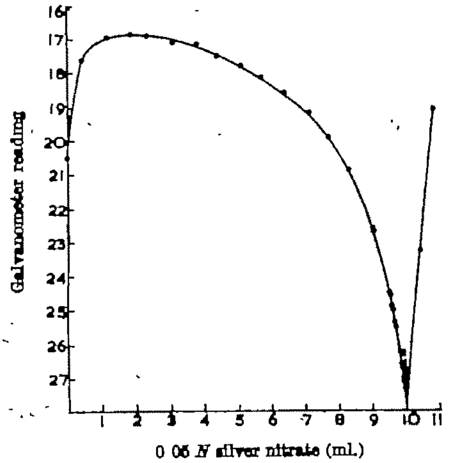

Fig. 2. Titration of 0·5 m.eq. of sodium chloride; electrolysis potential, 100 mV.

The first excess silver ions cause another current, this time governed by the reactions:

Cathode	Anode
$Ag^{\cdot} + e \rightarrow Ag$	$Ag \rightarrow Ag^{\cdot} + e$

Hence the equivalence point is indicated very sharply by the galvanometer (Fig. 2). The end point can be established without any graphical work.

This method is quicker and safer than a potentiometric determination of chloride[1] in consequence of its independence of any reference half-cell and the direct determination of the end point. Stirring of the solution is necessary; in order to be able to titrate in a small volume, we used a simple rotating titration vessel.

This titration makes possible a quick determination of the chloride content of plant material without destruction or filtration. Best (*l.c.*) showed that ashed samples give lower results, perhaps caused by a loss of chloride in the ashing process. We boiled the dried and ground sample with distilled water for half an hour, and titrated it in the same vessel without filtration. The following results indicate that in this way even better results may be obtained than after filtration of the plant sample.

Quantity of dried grass (gm.)	Treatment	Chloride content of the grass (per cent)	
1	Boiled, filtered, titrated in 50 ml.	0·91	0·92
1½	Boiled, filtered, titrated in 50 ml.	0·85	0·85
2	Boiled, filtered, titrated in 50 ml. After filtration, the grass was washed six times	0·76	0·77
½	Boiled, titrated in 50 ml. without filtration	0·94	0·94
1½	Boiled, titrated in 50 ml. without filtration	0·92	0·94

As the electrode system is reversible, the same electrochemical principle can be used for determining the silver ion concentration of any aqueous solution. This method is an application of the principle of the dead-stop end point titration (as described by Stone and Scholten[2]), using second-order electrodes as oxidation-reduction electrodes.

A detailed report on this electrometric titration technique and its applications in plant analysis will be published elsewhere.

Adrenaline, Noradrenaline and Hydroxytyramine in Extracts from Insects

EVIDENCE that the specific ergone of the adrenergic system in mammals is noradrenaline has been given by Euler[1]. So far, noradrenaline does not seem to have been demonstrated in extracts from insects.

As material in the present study, larvæ and adult insects of *Tenebrio molitor*, and larvæ, pupæ and

Table 1

Species	Tissue	Methods of extraction	Noradrenaline (μgm./gm. body-weight)	Adrenaline (μgm./gm body-weight)	Hydroxytyramine (μgm./gm. body-weight, approximate)	Adrenaline as percentage of adrenaline and noradrenaline
Tenebrio molitor, adults	Whole body	Trichloracetic acid	1·14	0·151	10–15	12
,, ,, larvæ	,, ,,	,, ,,	2·20	0·061	10–15	3
Apis mellifica, adults	,, ,,	,, ,,	0·75	0·050	5–10	6
,, ,, pupæ	,, ,,	,, ,,	0·22	0·026	2–4	11
,, ,, larvæ	,, ,,	,, ,,	0·30	0·005	2–4	2

adult insects of *Apis mellifica* were used. The insects were carefully freed from foreign material and weighed. After grinding in a mortar together with chemically pure sand, the tissue was extracted with three volumes of 6 per cent trichloracetic acid. The sympathomimetic catechol amines were adsorbed with the aid of aluminium hydroxide[2]. After evaporation *in vacuo* to suitable volume, the amounts of adrenaline and noradrenaline were determined by comparative tests on the cat's blood pressure and the hen's rectal cæcum[3]. The approximate amounts of hydroxytyramine were estimated by paper partition chromatography against known standard solutions of adrenaline, noradrenaline and hydroxytyramine after development with potassium ferricyanide[4] (Table 1).

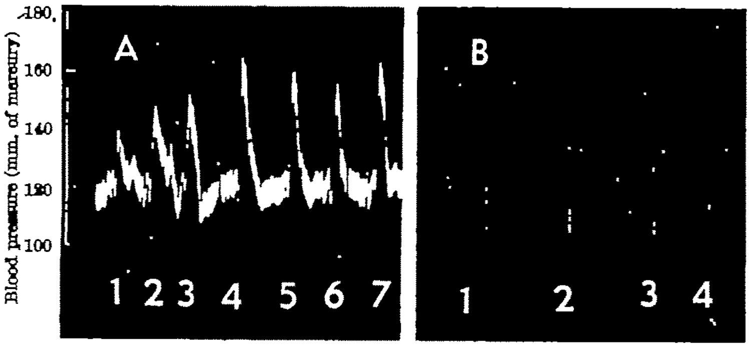

Fig. 1. (*A*) Cat's blood pressure. (1) 0·1 μgm. noradrenaline. (2) 0·4 μgm. adrenaline. (3) 0·15 μgm. noradrenaline. (4) 200 mgm. of *Tenebrio molitor* (adults). (5) 80 mgm. of *Tenebrio molitor* (larvæ). (6) 165 mgm. of *Tenebrio molitor* (adults). (7) 0·2 μgm. noradrenaline. Ordinate: Blood pressure, 100–180 mm. mercury. (*B*) Hen's rectal cæcum. (1) 64 mgm. of *Tenebrio molitor* (larvæ). (2) 0·3 μgm. noradrenaline. (3) 50 mgm. of *Tenebrio molitor* (adults). (4) 0·006 μgm. adrenaline

In purified extracts from *Tenebrio molitor* and *Apis mellifica*, three biologically active substances were demonstrated which by biological assay and paper chromatography were identified as adrenaline, noradrenaline and hydroxytyramine (see recordings reproduced herewith and Table 1). In extracts from other kinds of insects results in agreement with the above have been found. A full account of this work will be published in *Acta Physiol. Scand.*

Carbon Dioxide Fixation and Mitotic Poisons

VARIOUS categories of compounds have been classified as 'mitotic poisons' in the belief that the action mimicked that of a standard compound, such as colchicine. In some cases, such as the halogenated benzenes, it was known that these substances were not completely equivalent since, for example, they did not produce polyploidy[1]. The mechanism suggested whereby some substances were effective as poisons was interference with protein sulphydryl groups in particular and with carbohydrate metabolism in general[2]. It was of interest to test this hypothesis by determination of the extent of inhibition of reversible carbon dioxide fixation.

Six to eight excised onion or soybean roots, *c.* 1 cm. in length, were divided into two equal groups, one placed in the poison solution, the other in tap water. (In separate experiments, root-tip and elongation regions showed no profound differences.) Time and concentration conditions (3 hr., $2 \cdot 7 \times 10^{-3} M$ for colchicine; a saturated aqueous solution for the others, except where indicated) were such as to give the usual mitotic aberrations with the normal staining procedure. Following treatment, the roots were transferred to 1 ml. distilled water in a screw-cap vial. Equal aliquots of sodium bicarbonate (carbon-14) were added to treated and control vials, and the screw-caps replaced and tightened. After one hour contact time, the roots were dropped into boiling 80 per cent ethanol, in which the metabolic acids are extracted within no more than twenty minutes gentle refluxing. The extracts were then quantitatively transferred to small glass cones, air-concentrated there by a blower to *c.* 0·1 ml. and then transferred quantitatively to Whatman No. 1 sheets for subsequent chromatography. The amount of fixation was determined at this point by counting the original spot on filter paper directly with an end-window counter. The pattern of carbon dioxide fixation, details of which will be the subject of another communication, was always identical, regardless of the degree of inhibition. Inhibition therefore does not occur within the tricarboxylic cycle itself. Furthermore, soybean and onion roots displayed identical radiograms.

Bromobenzene is a typical substance which has been classed as a mitotic poison. Its time course of respiratory inhibition is given in Fig. 1. The undulatory nature of the initial aspects of the control may result from the excision immediately preceding the 10-min. equilibration. The inhibition is just as readily removed (cf. Table 1), and consequently standard

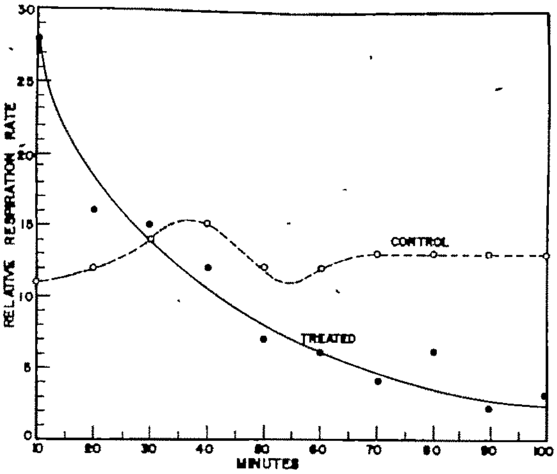

Fig. 1

practice consisted in the immediate transfer of roots from poison to bicarbonate solution. (Different levels of initial activity were used in different experiments, although control and treated were given identical aliquots. Consequently, absolute counts of different experiments cannot be compared, although ratios can. In the counting system used, where the geometry is c. 5 per cent, counts were of the order of 10^4/min. The infinite ratio indicates merely that treated samples were background within the statistical error used (± 5 per cent standard deviation). We do not infer that absolutely no activity is present.)

Table 1. Rate of Recovery of Roots from Treatment with Bromobenzene

Exp. No.	Equilibration time* (min.)	Ratio of activity control/treated
1*a*†	0	∞
1*b*†	0	∞
2	20	∞
3	30	3·0
4	40	2·2
5	50	1·3

† By courtesy of Dr. R. Weintraub, Chemical Division, Camp Detrick, Frederick, Md.

‡ This apparently indicates stimulation.

The experiments indicate that bromobenzene may act as a potent respiratory poison as do various other halogenated aromatic compounds. However, as is shown in Table 2, mitotic poisons such as colchicine and acenaphthene which act in very low concentrations (for example, c. 10^{-7} *M* and 10^{-4} *M*, respectively) and are able to exert an effect on respiration only at a much higher concentration (c. 10^{-3} *M*)[2] show no effect on reversible carbon dioxide fixation at the lower level. It is therefore quite possible that the halogenated aromatics, or any substance which inhibits a normal glycolytic pathway, will thereby affect mitosis indirectly. It does not appear proper, however, to classify such substances as mitotic poisons.

Effect of 2,2-*bis*(Parachlorophenyl)-1,1-Dichloroethane (DDD) on the Adrenal Cortex of the Rat

While DDD has been repeatedly shown to produce selective degeneration of the zona fasciculata of the adrenal cortex in the dog[1] when fed in daily doses of 50 mgm./kgm., no such effect has been found in rats receiving as much as 2,500 p.p.m. of the drug in the diet[2]. Physiological changes have been described in rats fed 1,000 p.p.m. DDD which have been attributed to adrenal cortical dysfunction[3], and histological damage has been reported after the injection of about 5 gm. over a period of 4–6 weeks[4]. Since a rat without zona fasciculata but with intact zona glomerulosa, adrenal medulla and pituitary would be of great help in the elucidation of certain problems of adrenal cortical function, attempts were made to produce degeneration of the zona fasciculata by injecting DDD in arachis oil. These attempts were unsuccessful, in agreement with the findings of Dr. I. C. Jones (personal communication) in both rats and mice, and so the regeneration of the adrenal cortex after medullectomy was observed in rats treated with DDD, since it was thought that this might be a sensitive test for a cytotoxic effect on the adrenal cortex.

Two groups of ten male rats (Porton strain), fed on M.R.C. Diet 41, were used, one group being given 20 mgm. DDD/100 gm. body-weight as a 4 per cent solution in arachis oil subcutaneously three times a week, the other group receiving an equivalent amount of arachis oil. DDD was obtained by recrystallization from a commercial sample of 'Rothane' (Rohm and Haas, kindly given by Charles Lennig and Co.). After the third dose, all the rats were medullectomized under ether by the method of Evans, as quoted by Ingle and Griffiths[5]. Treatment with either DDD or arachis oil alone was continued, and in addition the rats were given 1 per cent sodium chloride to drink for the first week after operation. Five rats in each group were killed at 14 days and the remainder at 28 days after the operation. The adrenals were weighed and examined histologically (hæmatoxylin and eosin: sudanophilia; birefringence after treatment with digitonin).

Before and after medullectomy, the DDD-treated rats appeared normal and grew at the same rate as the controls. The adrenal weights (mgm./100 gm. body-weight) of the treated group did not differ significantly from the controls either at 14 days (treated 10·0 ± 1·9, standard deviation); controls 9·8 ± 2·0) or 28 days (treated 10·7 ± 1·6; controls 10·9 ± 2·0). Histologically, the medulla was absent in all cases and the appearance of the cortex in paraffin sections (hæmatoxylin and eosin) was the same in the two groups. The distribution of sudanophilic lipid and birefringent crystals after treatment with digitonin was also the same in the two groups, both from the points of view of amount and of size of the droplets or crystals.

Under these experimental conditions, DDD did not interfere with the regeneration of the adrenal cortex after medullectomy, suggesting that it does not exert any striking cytotoxic effect on the rat adrenal cortex. The effect of this compound in the dog may be due to a greater susceptibility of the adrenal cortex to toxic agents in that species, in which spontaneous adrenal cortical atrophy can occur[6].

The Epineurium as a Diffusion Barrier

ACCORDING to Lorente de Nó[1], it is "utterly impossible to believe that the connective tissue sheath of frog or bullfrog nerve could act as a diffusion barrier that would delay for considerable periods of time the penetration of solutes into the nerve". This statement, reaffirmed in subsequent publications[2-4], is diametrically opposed to the results of other authors who believe that both 'desheathed' nerves and individual nerve fibres react to a variety of substances much more rapidly than do intact nerves[5-11]. Lorente de Nó[4], on the other hand, points out that neither the perimysium[12], which resembles a nerve sheath in structure, nor the connective tissue sheath of the squid axon[13] functions as a diffusion barrier. He therefore refuses to allow a similar claim in the case of the frog's sciatic nerve, the sheath of which is no denser than the structures just mentioned. As further evidence, Lorente de Nó points out that the post-ganglionic trunk of the cat's superior cervical ganglion in microscopic section is claimed to show continuity between collagen fibres of epineurium and endoneurium.

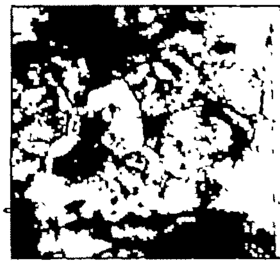
TIME OF APPEARANCE, AFTER TREATMENT WITH 0·5 PER CENT SILVER NITRATE, OF ENDOTHELIAL CELL BORDERS AND NODES OF RANVIER IN THE PERIPHERAL AND CENTRAL FIBRES OF THE PERONEAL TRUNK OF THE FROG.

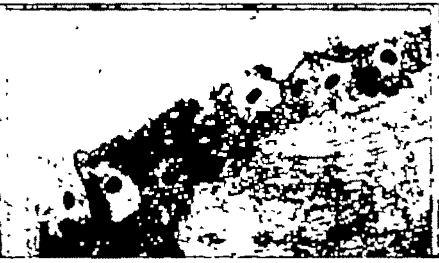
Each Point in this Table Represents at Least Five Measurements

	Endothelium cell borders (min.)	Nodes of Ranvier in outer fibre layers of peroneal nerve (min.)	Nodes of Ranvier in central fibre layers of peroneal nerve (min.)
Intact nerve	3	70–90	80 and more
Intact nerve treated with chloroform	–	3	10
'Desheathed nerve'	–	3	5

Since, however, the experimental evidence involves somatic nerve bundles such as the peroneal, tibial and sciatic nerves of frogs and bullfrogs, it would seem more useful to study the microscopic anatomy of these nerves. Work on these lines has shown that the epineural sheath of these nerves—and also of similar nerves in mammals—does not merely consist of more or less dense connective tissue. Key and Retzius[14] and Ranvier[15] found, as was pointed out recently by Huxley and Stämpfli[8], a lamellar structure which surrounds the nerve trunk. This structure consists of two endothelial lamellæ lying on top of each other, enclosing a fine gap which, according to Key and Retzius[14], communicates with the subarachnoid space of the central nervous system. This gap shows no structural elements connecting the epineurium with the endoneurium. Even in preparations of the entire nerve, the limits of the endothelial cells can be readily shown by the use of silver nitrate (Fig. 1). By impregnation with lead-nitrate and subsequent treatment with yellow ammonium sulphide, the nuclei and borders of the endothelium-like cells can be made visible (Fig. 2). If the tissue is stained after the usual fixation and embedding, the structure can still be clearly distinguished from connective tissue, although cell borders are not seen (Fig. 3). Neither the perimysium nor the sheath of squid axon have any such structure; Lorente de Nó's comparison therefore does not hold.

Treatment of myelinated nerve with silver nitrate before fixation is commonly used for making the nodes of Ranvier visible. Their time of appearance in an intact and in a 'desheathed' peroneal trunk of the frog (*R. temporaria*) is shown in the accompanying table. In both, nodes of Ranvier can already be seen after exposure to 0·5 per cent silver nitrate for 3 min., provided that the intact nerve trunk was treated





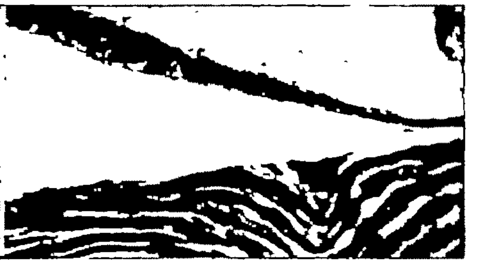


Fig. 1. Sciatic nerve, frog. Borders of endothelium cells, stained for 5 min. with 0·5 per cent silver nitrate. × 110

Fig. 2. Sciatic nerve, dog. Limits and nuclei of the epineural endothelium. Lead nitrate 5 per cent, buffered with acetate at pH 4·9, 8 days at 37° C. Visualization by yellow ammonium sulphide. Frozen section. × 170

Fig. 3. Sciatic nerve, rabbit. The endothelium has been lifted from the underlying nerve trunk by an artefact. Nuclei and cytoplasm are visible, although cell borders are not seen. Nerve stained with Bodian's silver method after paraffin embedding. × 350

with chloroform beforehand. In intact nerve, however, stained with the same solution without prior treatment with chloroform, only the cell borders of the endothelial barrier can be seen after the same interval. In these circumstances, between 70 and 90 min. must elapse before the endothelial barrier is passed, and nodes of Ranvier begin to show.

It is concluded, therefore, that somatic nerves of frogs, dogs, rabbits and cats are surrounded by an endothelium-like double membrane. Its endothelial layers constitute a definite barrier to the diffusion of silver nitrate.

I wish to thank Prof. A. von Muralt, of Berne, for giving me facilities for this investigation and for his continued interest and advice, Prof. J. M. Yoffey, of Bristol, for assisting with the translation of this communication into English, and the Deutsche Forschungsgemeinschaft for financial support.

A Soluble Form of Reconstituted Collagen

IN attempting to repeat some experiments reported by von Buzágh[1], it was noticed that the fibrous precipitate (Fig. 1), formed by adding a 10 per cent sodium chloride solution to a solution of calf Achilles tendon in 1·2 per cent acetic acid, dissolved in 0·9 per cent sodium chloride; on dialysis of this solution, a fibrous precipitate was re-formed. In contradistinction, the precipitates obtained from solutions of tendon in acetic acid at concentrations more generally used (0·01–0·4 per cent)[2] are insoluble in 0·9 per cent sodium chloride. The physical properties of reconstituted collagen thus vary according to the concentration of the acetic acid used for dissolving the original tendon.

Solution in 0·9 per cent sodium chloride occurred rapidly; but examination of the material just before final solution revealed masses of tapered rod-like structures approximately 2–5 μ in length, individual rods sometimes showing end-to-end aggregation (Fig. 2). In order to study the process of solution more closely, the precipitate obtained with 10 per cent sodium chloride was shaken with concentrations of sodium chloride varying from 0 to 5 per cent and examined microscopically. The fibre aggregates were first split longitudinally, so that in 2 per cent sodium chloride the precipitate consisted mainly of long fine filaments. Below this concentration the filaments appeared to be broken transversely into short rod-like structures.

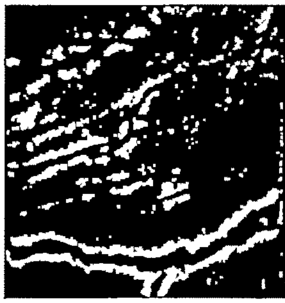

Fig. 1. Fibres obtained by 10 per cent sodium chloride from a solution of tendon in 1·2 per cent acetic acid. Phase-contrast microscopy. (× 350)

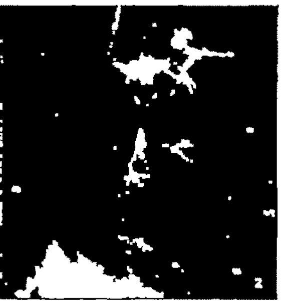

Fig. 2. Tapered rods formed during solution of reconstituted collagen in 0·9 per cent sodium chloride. Dark ground illumination. (× 400)

In another experiment, sodium chloride to a final concentration of 1–5 per cent was added to aliquots of a solution of tendon in 1·2 per cent acetic acid. With 1 per cent sodium chloride no precipitate was formed. With 1·5 per cent the precipitate was granular; at 2 per cent the precipitate contained granular material, long fine filaments and the rod-like structures; at 2·5 per cent and higher the precipitate was wholly fibrous.

It seems likely that these different forms represent intermediate stages in the building up of the fibre aggregates, the granular material forming rod-like structures which link end to end to form long fine filaments, and that these in turn aggregate at right angles to their long axis to form the thicker fibres. The linkages must be weak since the fibres are easily broken up by 0·9 per cent sodium chloride solutions, first into filaments, then into rods, and finally going into solution. However, when chondroitin sulphate is used as the precipitating agent, the resulting fibres are insoluble in 0·9 per cent sodium chloride. If these fibres are incubated with hyaluronidase, which is known to break down chondroitin sulphate, they become soluble in 0·9 per cent sodium chloride with the intermediate formation of the rod-like structures. This suggests that chondroitin sulphate strengthens both the transverse and end-to-end linkages in this type of reconstituted collagen, and strengthens the evidence previously presented[3] that chondroitin sulphuric acid is concerned in stabilizing the structure of tendon.

Lævanpolyase

SUCROSE in the culture of a lævan-forming micro-organism might be converted into invert-sugar directly by invertase, or less directly by lævansucrase[1] acting in conjunction with a lævan hydrolase[2]. An enzyme which does not cleave sucrose either hydrolytically or polymeratively and which hydrolyses a high polymer lævan has been designated 'lævanpolyase', and has been separated by us from the culture fluids of two lævan-formers (*Azotobacter* *chroococcum* and *Bacillus asterosporus*) growing on lævan. The study of this enzyme has helped define the role of lævan as an intermediary of the process whereby lævan-forming micro-organisms may utilize sucrose totally.

Lævanpolyase was freed from lævans and reducing sugars and obtained as a water-soluble transparent gel by precipitation with ammonium sulphate (50 per cent saturation) from the extracellular fluid of a young culture of *Azotobacter chroococcum* growing in a thin fluid layer on agar containing lævan of *Aerobacter levanicum* as sole source of carbon. The enzyme produced loss of turbidity in lævan solutions and an attendant restricted hydrolytic cleavage of the polymer. At the end of the reaction, the reducing power corresponded to approximately 18 per cent total hydrolysis.

The lævan digest was fractionated with alcohol and the recovered fractions were exposed to the further action of fresh enzyme. With this procedure the mixture of the true limit lævans was afforded. The latter were resolved by alcohol fractionation and paper chromatography, and the resolved components were characterized on the basis of reducing power, precipitability by alcohol, lability to invertase, and velocity of migration in paper. Reference oligolævans were prepared from lævan by partial acid hydrolysis. The distribution of weight of the homologues in the reaction mixture of the exhaustive degradation of the lævan by lævanpolyase was: fructose, 0; lævanbiose, 0; lævantriose plus lævantetraose, approximately, 20; higher members of lævan homologue series (average polymerization degree = 11), approximately 80.

The important features are: (*a*) that lævan is converted by lævanpolyase not into a single limit product but into a mixture; and (*b*) that this mixture contains neither fructose nor lævanbiose. Consistent with these features is the assumption that the *Aerobacter* lævan molecule, at sites at least three fructose units distant from the chain terminals, contains anomalous or branch linkages[3], and that lævanpolyase hydrolyses these specifically. On the other hand, if the *Aerobacter* lævan molecule is a linear chain free from anomalous linkages, lævanpolyase would have to be regarded as a selective endotype enzyme which only cleaves the typical lævan interfructosidic linkage if it is in a chain of sufficient length and at a locus sufficiently distant (3 or more fructose units) from the chain terminals. A structural study of the *Aerobacter* lævan to decide between these alternatives is under way.

The lævanpolyase preparation hydrolysed inulin only very slowly; it failed completely to cleave sucrose either hydrolytically or polymeratively. It failed to split lævantriose and related low oligolævans. These (lævantriose, lævantetraose) were, however, readily hydrolysed totally to fructose by yeast invertase, which is inert towards the native lævan. Lævanpolyase is therefore probably distinct from hitherto recognized fructosidase entities.

When this *Azotobacter* was grown on sucrose rather than on lævan as source of carbon, the extracellular fluid of the culture hydrolysed lævan to well beyond the limit which was characteristic of the lævanpolyase reaction. Chromatographic analysis of the digest at different stages of reaction revealed consistently in this case the presence of fructose, lævans of relatively high molecular weight, and little or no lævanbiose, lævantriose or lævantetraose. Unlike the preparation of enzyme from the lævan-grown cells, that from the sucrose-grown cells hydrolysed sucrose.

On the basis of these findings, a scheme of the metabolism of sucrose via lævan by cultures of lævan-formers has been formulated. The scheme postulates a sequence of three, essentially irreversible, repetitive reaction steps:

$$\text{(1)}\quad \text{Sucrose} \xrightarrow{\text{lævansucrase}} \text{lævan} + \text{glucose};$$

$$\text{(2)}\quad \text{Lævan} + \text{water} \xrightarrow{\text{lævanpolyase}} \text{limit oligolævans};$$

$$\text{(3)}\quad \text{Limit oligolævans} + \text{water} \xrightarrow{\text{lævanoligase or sucrase}} \text{fructose}.$$

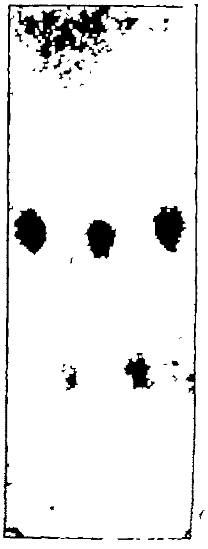
Association of Xylan with α-Cellulose in Jute

DAS *et al.*[1] have recently reported (without reproducing any photograph) the presence of xylose (and also arabinose) in the α-cellulose from jute, in contradiction to our finding[2]. Formic acid, used instead of sulphuric acid for hydrolysis, is stated to have achieved the result. To check this, we have repeated both the procedures; experimental facts do not, however, indicate the superiority of formic acid. Purified α-cellulose ('furfural' content 0·7 per cent) from jute, hydrolysed with 85 per cent formic acid at 135° for 12 min., as was done by Das *et al.*, was used for obtaining the photograph reproduced; the original spots (in triplicate), marked with *X*, represent the hydrolysate and *Xyl* (in duplicate) stands for pure xylose. Neither xylose nor arabinose could be detected. Whatman No. 1 filter paper strip, 57 cm. long, was employed, *n*-butanol, acetic acid and water being the solvent; the sugars were fixed with aniline hydrogen phthalate.



α-Cellulose, hydrolysed with formic acid, gives a faint but distinct spot below that for xylose. This was also observed when pure glucose (Baker's Analysed) or α-cellulose from purified cotton was treated with formic acid as stated above, but not with sulphuric acid. If in paper chromatography the solvent is not 'overrun', this spot might be mistaken for xylose. The α-cellulose from jute must be carefully purified, if necessary by repeated treatment with caustic soda solution (10–5 per cent), so as to reduce its furfural content to less than 1·0 per cent, otherwise traces of xylose may appear in the hydrolysate and so in the paper chromatogram. When pure xylose ('Difco') was treated with formic acid, as mentioned above, and also with sulphuric acid, as stated in our earlier communication, 83·5 and 87·8 per cent respectively could be recovered. Xylose, therefore, is not more resistant to formic acid than to sulphuric acid under the conditions of experiment.

'Lipase' in Gland Duct Epithelium and in Mucus-secreting Cells

The presence of 'lipase' in the acini of the pancreas and in the cells of the liver is well known, and these two tissues have provided the main material for chemical and histochemical studies of this enzyme. Less attention has been paid to the distribution of this enzyme in other parts of the alimentary tract, though Gomori[1] has described a number of observations. A systematic investigation of this tract, undertaken by means of Gomori's 'Tween' technique[2] (employing 'Tween 40') with some modification[3], has brought out some facts of interest which warrant a brief recording. It is realized that although the term 'lipase' is used here, the histochemical reaction given by the 'Tween' technique probably demonstrates an esterase in most sites rather than true lipase[4].

The alimentary tract of the following species has been studied: dog, cat, rabbit, guinea pig, mouse and rat; and of the variety of observations, the following seem particularly worthy of note.

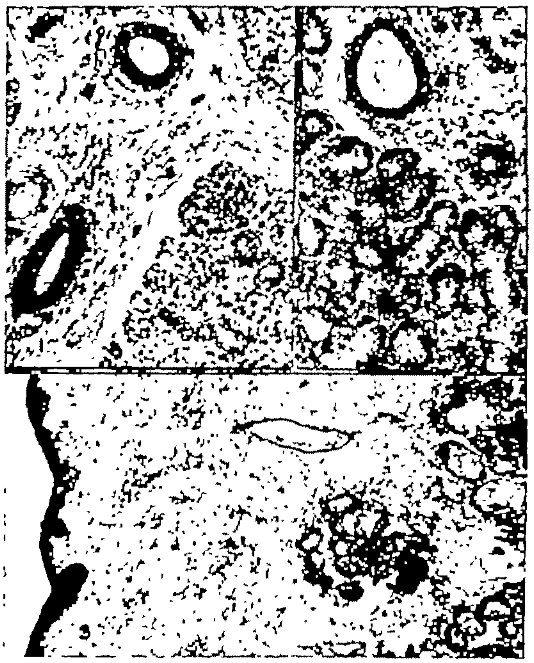
It was found, rather surprisingly, that the epithelium lining the ducts of certain glands commonly showed quite a strong reaction for 'lipase'. This was the case with the ducts of the salivary glands of all the species investigated except the rat (Figs. 1 and 2). The reaction was given particularly by the larger interlobular ducts rather than by the small intralobular ducts, though in some cases both segments of the ducts were found positive. The contents, however, of these ducts were invariably negative.

The mucus-secreting cells lining the ducts of the gastric glands, both of the fundus and pylorus, were positive in some species (dog, cat and rabbit), the pylorus giving the weaker reaction; but in the mouse and guinea pig, the reaction was feeble throughout the ducts of the gastric glands.

In the pancreas, the larger ducts were positive, and here their contents also, which conforms with the active lipase secretion of this organ.

Even in the liver of all the species examined, there was sometimes a slight reaction in the interlobular bile-ducts; and the gall bladder showed a weak patchy reaction in the lining epithelium, but not in its contents.

Another striking feature was a positive 'lipase' reaction given by mucus-secreting cells. In salivary glands, for example, it was more often the case that mucous acini reacted rather than serous (Figs. 1 and 2), though 'special' serous acini such as those of the submaxillary gland of the guinea pig reacted strongly, as was first shown by Gomori[1]. Again, the mucus-secreting acini of the œsophageal glands of the dog gave a particularly strong reaction (Fig. 3). Incidentally, their ducts were negative. The reaction of the mucus-secreting cells lining the ducts of stomach glands has already been referred to. The cells of the actual fundic glands were negative in dog, cat and rabbit; but in the guinea pig and mouse, the chief cells often gave a strong reaction.



(1) Parotid gland of dog. × 100. 'Lipase' reaction in epithelium of large interlobular ducts, but not of intralobular ducts. Serous acini negative

(2) Submaxillary gland of dog. × 100. 'Lipase' reaction in epithelium of large interlobular ducts. Strong reaction in mucous acini, especially at the bases of the cells.

(3) Œsophagus of dog. × 45. Strong reaction for 'lipase' in the mucous acini of the œsophageal glands, especially at the bases of the cells. Gland ducts are negative. Surface epithelium strongly positive as in other species.

All specimens were lightly counterstained for nuclei with hæmatoxylin

The mucous cells of Brunner's glands were always negative. But, in the peculiar case of the rabbit, the serous cells, which are present among the mucous acini of Brunner's glands, were positive (see also Gomori[1]). These cells are believed to represent pancreatic tissue, and thus their positive reaction for 'lipase' may add a point in favour of this view.

Goblet cells of both the small and large intestine appeared to be negative in the species studied.

From the results, certain points particularly stand out. First, gland ducts are probably not so inert physiologically as is commonly supposed, even the larger 'collecting' ducts displaying a reaction for 'lipase'. This seems to suggest a very specific activity of these cells, which may be concerned, if only indirectly, with the final composition of the secretion of the gland. However, it would be rash to conclude that the presence of the enzyme in duct epithelium, or for that matter in glandular cells themselves, does of necessity indicate that the enzyme itself forms part of the gland's secretion. In fact, if one may judge from the lack of histochemical reaction in the duct contents of some of these glands (for example, salivary glands, liver, dog oesophageal glands), it seems unlikely that this is the case. Secondly, the unexpected reaction in mucus-secreting cells at some sites and absence of such a reaction in cells of this type at other sites draw a new distinction between cells of this class.

Reflex Stimulation of the Neurohypophysis (Posterior Pituitary Gland) and the Nature of Posterior Pituitary Hormone(s)

THE sensory stimulus of suckling evokes nervous reflex release of the oxytocic substance from the neurohypophysis, which in turn stimulates the contractile tissue of the breast and causes a rise of milk pressure in the mammary ducts[1]. Electrical stimulation of the nerve supply (the supraopticohypophysial tract) of the neurohypophysis, or injection of posterior pituitary extracts (especially the oxytocic fraction)[2], elicits similar effects on the breast. Rise in intramammary duct pressure produced by injection of the oxytocic substance, or by excitation of the milk ejection reflex alone, does not usually result in free flow of milk to the exterior, possibly because of some sphincter-like mechanism at the nipple. In some cases, however, excitation of the milk ejection reflex results in dribbling of milk from a nipple that is not being suckled or milked; for example, the flow that may occur from the unsuckled breast of a nursing woman or from the udder of a cow subjected to routine procedures preceding milking.

In 1947 it was suggested[3] that coitus results in a nervous reflex release of oxytocic substance from the neurohypophysis and thereby an increase in uterine activity and increased speed of transport of seminal fluid up the female reproductive tract. It is therefore of interest that milk ejection has been observed to occur during coitus in one lactating woman[4]; and further information has now been collected from the wives of scientific colleagues. Of twenty-two questioned, thirteen had coitus during the period of lactation, and of these, six noticed that a discharge of milk accompanied some phase of the act of coitus. Complete orgasm does not seem to be essential for the mammary response, since two of the women who observed milk discharge had only incomplete excitation and a third reported that milk ejection preceded the orgasm. Seven women did not observe discharge of milk during coitus; but of these, two noticed a tingling sensation in the breasts which they stated was identical with the sensation accompanying milk ejection evoked by suckling. It seems clear, therefore, that discharge of milk may be excited by the act of coitus, and since there is good experimental evidence that milk ejection is dependent on discharge of the oxytocic substance from the neurohypophysis, it is reasonable to conclude that the sensory stimuli associated with mating cause nervous reflex release of the oxytocic substance. This conclusion is supported by the finding that coitus in the cow results in increased uterine motility[5], which is interpreted as being due to the release of the oxytocic substance.

The problem of how many hormone(s) the neurohypophysis secretes has never been clearly answered. Until a method is developed for assaying the oxytocic substance in venous blood, the most reliable approach would seem to be the measurement of various activities attributable to posterior pituitary activation (inhibition of a water diuresis, milk ejection and uterine contractions) which are excited by different 'physiological' stimuli. Stimuli which might be expected (on teleological grounds) to result in either an antidiuretic effect or an oxytocic effect do, in fact, result in both effects. Thus (1) an increase in the osmotic pressure of carotid blood results not only in an inhibition of water diuresis[6] but also in milk ejection[7] and increased uterine motility[8]; (2) suckling results not only in milk ejection[1] but also in an antidiuresis[9]; (3) coitus results not only in milk ejection (see above) and increased uterine motility[5], but also in an antidiuresis[10].

At the moment, this evidence suggests that the neurohypophysis secretes one hormone with multiple activities. If this is so, it is likely that the substance liberated from the gland has a higher proportion of oxytocic to antidiuretic activity than have standard whole posterior pituitary extracts[3,9,11].

Proprioceptive Fibres in the Ocular Muscles of the Pig

THE sensory innervation of the ocular muscles differs from that of skeletal muscle generally, both in the calibre of its fibres and in the nature of their endings. Studying the pattern in human, cat and rabbit material, Woollard[1] found that, whereas motor end-plates conform to the orthodox structure, the sensory element of the extra-ocular muscles consists of a system of fine lightly myelinated fibres, terminating—usually on relatively small muscle fibres—in claw-like endings which may be either free or ensheathed, simple or complex.

The origin of the sensory component of the IIIrd and IVth nerves was investigated by Tarkhan[2], who found in cats an intimate connexion between the fibres of the mesencephalic Vth root and those of the spino-tectal and oculomotor nerve bundles. He also traced a varying number of mesencephalic Vth fibres directly into the trochlear nerve at the level of its decussation.

The early myelination of the mesencephalic Vth root in the pig facilitates the study of its distribution in this animal. We removed the brain stems of twelve pigs (aged from one day to four weeks old), after perfusion of the head with 5 per cent formol-saline. Paraffin sections of Bielschowsky silver preparations were taken in both coronal and transverse planes. Transverse sections of the mid-brain at the level of the trochlear nucleus show the mesencephalic Vth root at maximum development. The bundles of the dorsal segment can be seen passing towards the trochlear decussation; lateral bundles, forming the greater curvature of the root, contain large heavily myelinated fibres descending to the sensory Vth root. In the ventral segment the fibres are much reduced in calibre; the bundles—larger here than elsewhere—decrease in number and ultimately merge into the medial longitudinal fasciculus.

Coronal sections through the dorsal aspect of the brain stem demonstrate clearly a mesencephalic Vth root contribution to the trochlear nerve. The dorsal segment of the root runs medial to the tecto-spinal tract, and, at the level of the anterior medullary velum, curves towards the aqueduct to enter the velum with the IVth nerve.

The origin of the oculomotor sensory component is more complex. We were unable to trace any direct connexion between the mesencephalic Vth root and the nuclei or fibres of the IIIrd nerve, and no sensory-type cells were seen in the nuclei or on the intra-cranial course of the issuing fibre bundles. There are here two possibilities to be considered: first (as suggested by Tarkhan), the passage of mesencephalic root fibres in the tecto-spinal tract, and their transference to the oculomotor bundles in the course of the tecto-spinal decussation; secondly, the existence of internuncial cell groups. The nucleus of Darkschewitsch and the interstitial nucleus may have special significance in this connexion, since they have been excluded by Warwick[3] from radicular participation in the oculomotor complex.

A further and more comprehensive investigation of the problem is now being undertaken. The work is assisted by a grant from the Medical Research Council of Ireland.

Transplantation of Nuclei in Newt's Eggs

ONE of the most fundamental problems, both for genetics and embryology, is that of whether the genes in the nuclei of differentiated tissues retain their full range of capacities, or whether some irreversible alteration affects them. The most direct method of investigating this is to develop techniques which permit the transplantation of nuclei from differentiated cells of one kind into enucleated cells of different developmental potentialities. Briggs and King[1] have reported some attempts in this direction, in which nuclei from blastulæ or early gastrulæ of frogs were injected into uncleaved but fertilized frogs' eggs from which the zygote nucleus had been removed. Nuclei from blastulæ permitted the full differentiation of a normal embryo in a fairly high proportion of cases, those from early gastrulæ in a smaller proportion, whereas those from determined (but not yet differentiated) tissues gave little success, though it remained uncertain whether this was due to technical difficulties or to an incapacity of the genes.

During the past summer, we have carried out somewhat similar experiments with the eggs of the newt *Triturus palmatus*. Methods for removing the zygote nucleus from whole eggs have not been developed in this species. We therefore adopted the method of cutting the newly fertilized egg in half by laying a thin glass rod across it after removal of the vitelline membrane. The halved eggs were then left to complete the first two divisions; usually only one side, containing the zygote nucleus, underwent division, but in some cases (presumably when the egg at the time of operation was in anaphase) a nucleus was included in both halves, and both divided; such eggs were discarded. After it had been ascertained which half contained the zygote nucleus, one or more nuclei (accompanied by a little cytoplasm) were injected into the non-nucleated half. Cells for the injection were prepared by disaggregating portions of embryos in alkaline saline. An isolated cell was drawn into a pipette of a size suitable to break the cell membrane but to leave the nucleus intact, and injected as deeply as possible into the recipient cytoplasm. There was a tendency for the injected nucleus to emerge again as the pipette was withdrawn. When it was thought that this had occurred, a second nucleus was sometimes injected into the same egg. Operations were made in Holtfreter solution, and the injected eggs after healing were cultured in one-tenth strength Holtfreter.

Table 1. NO. OF EGGS INJECTED AND STAGE REACHED

Eggs injected	Donor	Abnormal cleavage	Normal cleavage	Reached blastula stage
34	Blastula	9	10	5
61	Early gastrula	13	12	7
20	Late gastrula	2	9	6
34	Neural plate	4	13	0

The results are summarized in Table 1. It will be seen that a reasonably high proportion of injected eggs cleaved, but none of them succeeded in completing gastrulation, even when the injected nucleus came from a blastula. The eggs usually formed a spherical ball of cells, superficially like a late blastula; but the cells composing it did not adhere firmly to one another, and there was usually no proper blastocoel, the whole interior being filled by a mass of isolated spherical cells which were immediately extruded if the surface was slightly wounded. Nuclei from determined stages (gastrulæ with yolk plug or slit blastopore) gave results essentially similar to those from earlier stages. There is therefore no reason, from these experiments, for attributing the failure of gastrulation in the injected eggs to an incapacity in the nuclei of determined tissues. It seemed more probable that the technique in general was inadequate, perhaps because of damage done to the surface coat. Preliminary attempts to overcome this have been made by transplanting the experimental blastulæ into the blastocœl of a normal embryo; but so far all such material has still broken down into isolated cells which suffer pycnotic degeneration of the nuclei within a short period. Some injections of nuclei have also been made into enucleated parts of eggs which remained within their jelly capsules and membranes. One of these showed some signs of forming a blastopore; but the tendency to break down into isolated cells was still not fully overcome. It is hoped, however, that in future work the technique can be improved by some such method as this.

Rapid Staining of Intestinal Amœbæ on Wet Mounts

IN unstained preparations of intestinal amœbæ, the size, type of pseudopodia, movement and cytoplasmic inclusions enable one to distinguish the different species; but the characteristic staining of the nucleus leads to correct identification. For permanent preparations, hæmatoxylin staining and its various modifications are useful, but they are time-consuming. Hence various rapid staining methods have been advocated in recent years.

Experimenting with *E. histolytica*, *E. coli* and *E. terrapanae* obtained from cultures, and some of the rapid stains like Velat's[1], Quensel's[2] and J. S. B.[3], I noted that the *p*H of the staining solution was more important than the stain itself.

This was confirmed by using three buffer solutions on samples from cultures of amœbæ referred to above and also specimens of *E. histolytica*, *E. coli* and *E. nana* from patients. At certain *p*H-levels, the buffer solutions by themselves rendered the nuclei of trophozoites and cysts refractile, bringing out clearly all the morphological details. For the trophozoites of *E. histolytica*, the optimum *p*H with an acetate buffer was 4·0–4·8; with phthalate and citrate buffers, the *p*H required was 2·5–3·0. The vegetative forms also stained well with the different stains at various *p*H levels. The optimum *p*H for Velat's stain as 0·05 per cent solution in acetate buffer was 4·0–4·8, and with phthalate buffer it was 3·5. Solution I of J. S. B. stain prepared from the powder form[4] gave equally satisfactory results with acetate buffer at a *p*H of 3·5 and phthalate buffer 2·5 when used as a 0·1 per cent solution. Further, simple dyes like pyronine (1 per cent) and methylene blue (0·5–0·0125 per cent) in acetate buffer at *p*H 3·5 also produced the same results as Velat's and J. S. B. The cysts, however, required a low *p*H (1·25–1·35).

This work was carried out in the laboratories of the Parasitology Department of the School of Hygiene and Public Health, Johns Hopkins University, Baltimore, United States.

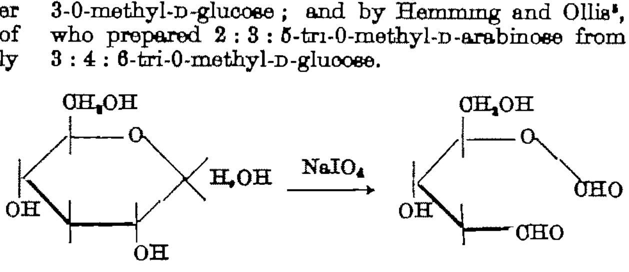
A New Synthesis of 2-Deoxy-D-ribose

A SATISFACTORY synthesis of 2-deoxy-D-ribose, a sugar of very wide distribution in Nature, has not yet been achieved. Hitherto, the published synthesis with the highest overall yield is that of Deriaz, Overend, Stacey, Teece and Wiggins[1], who prepared it in yields of about 10 per cent from D-arabinose via D-arabinal. In an attempt to obtain improved yields of 2-deoxy-D-ribose, a partial oxidation of 3-deoxy-D-glucose with sodium metaperiodate was carried out. This reaction succeeded, but gave the desired product in only 29 per cent yield. This type of reaction, carried out under mild conditions, offers a method of preparation of derivatives of 2-deoxy-D-ribose from those of 3-deoxy-D-glucose.

In a trial experiment, 3-deoxy-D-glucose[2] (I) (62 mgm.) in water (25 c.c.) was oxidized with 0·19 *N* sodium metaperiodate (1·26 moles; 5 c.c.). Samples were taken at intervals and the uptake of periodate and formic acid production measured. The initial rapid uptake of periodate ceased after 190 min., by which time all the reagent had been consumed and only 0·51 mole of formic acid had been formed. Thereafter the formic acid titre was found to increase very slowly, only 0·56 mole of the acid being present after 600 min. The slow production of formic acid is probably due to the slow hydrolysis of 2-deoxy-4-formyl-D-ribose (II). This compound is stable to periodate, thus facilitating the isolation of 2-deoxy-D-ribose. The above type of reaction has been used by Fried and Walz[3] to prepare 2:5-di-O-methyl-D-arabinose from 3:6-di-O-methyl-D-glucose; by Barker and Smith[4] to prepare 2-O-methyl-D-arabinose from 3-O-methyl-D-glucose; and by Hemming and Ollis[5], who prepared 2:3:5-tri-O-methyl-D-arabinose from 3:4:6-tri-O-methyl-D-glucose.



(I) (II)

The 2-deoxy-D-ribose was prepared as follows. 3-Deoxy-D-glucose (0·337 gm.) was dissolved in a solution containing 0·19 *N* sodium metaperiodate (1 mole; 21·6 c.c.). After 3 hr., a 5 per cent solution of barium acetate was added, and the resulting precipitate was discarded. The solution was kept slightly alkaline by the dropwise addition of ammonium hydroxide until deformylation was complete (about 15 min.). The solution was then de-ionized by passage through columns of the ion-exchange resins

'Amberlite IR-120' and 'IR-4B'. The effluent was evaporated under reduced pressure to a syrup, which contained 2-deoxy-D-ribose and unchanged 3-deoxy-D-glucose. This was fractionated by chromatography on several large sheets of Whatman No. 1 filter paper[4] (solvent, butanol : ethanol : water, 40 : 11 : 19 v/v). The 2-deoxy-D-ribose was eluted from the appropriate strips of paper with cold water and the aqueous solution evaporated to a syrup (80 mgm.), $[\alpha]_D^{20} - 31°$ (c, 1·0 in water). The syrup was characterized by the formation of N-phenyl-2-deoxy-D-ribosylamine prepared by refluxing it in ethanolic solution with one equivalent of aniline[1]. The product, after two recrystallizations from ethanol, had melting point and mixed melting point 169–170°, $[\alpha]_D^{20} + 141°$ (12 min.) → + 47° (72 hr., constant value) (c, 0·40 in pyridine); and analysis gave C, 63·3; H, 7·2; N, 6·2 per cent; calculated for $C_{11}H_{15}O_3N$: C, 63·2; H, 7·2; N, 6·7 per cent.

Amount of Gamma-Benzene Hexachloride picked up by Resistant Houseflies bred on a Medium containing Benzene Hexachloride

New information on the nature of resistance of the housefly, ***Musca domestica***, to benzene hexachloride (BHC) was obtained in the course of experiments comparing the pick-up of gamma-benzene hexachloride by normal flies (Hawthorndale stock) with that by a strain having very high resistance to this insecticide.

The resistant flies originated in Uruguay, but had since been reared through many generations to yield a strain the larvæ of which were able to tolerate 0·5 per cent gamma-benzene hexachloride in their food. Those here considered had been reared throughout their larval life on a diet containing this amount of toxicant. The pupæ were removed by flotation, and the flies, which were allowed to emerge in clean jars, were fed on uncontaminated milk and sugar.

Three days after emergence the adult flies were exposed to deposits of carbon-14 labelled gamma-benzene hexachloride on filter paper inside a Petri dish for periods varying from 15 min. to 16 hr. The benzene hexachloride picked up was separated as two fractions, 'outside' and 'inside', using a technique similar to that described by Armstrong, Bradbury and Britton[1]. The 'outside' fraction, obtained by rinsing the insects with carbon tetrachloride, we regard as being in the superficial layers of the epicuticle; the 'inside' fraction, obtained by grinding the rinsed insects with anhydrous sodium sulphate and extracting with carbon tetrachloride, comprises the insecticide in the internal insect tissues. Both fractions were determined by combustion to carbon dioxide, which was isolated as barium carbonate for counting. Results of several experiments, each with twenty female flies, are summarized in Table 1.

Table 1. Amount of Gamma-Benzene Hexachloride picked up by Flies (in µgm./gm. Fly) determined Radiochemically

Time of exposure (hr.)	Non-resistant			Resistant			Difference between totals
	'Outside'	'Inside'	Total	'Outside'	'Inside'	Total	
¼	13	11	24	5	1	6	18
1	19	21	40	13	8	21	19
2	17	26	43	15	15	30	13
4	19	34	53	20	32	52	1

It is clear that in the first two hours, resistant flies picked up less carbon-14-labelled benzene hexachloride than normal flies, both 'outside' and 'inside'.

As it was possible that the resistant flies already contained benzene hexachloride transmitted from earlier stages (Hoskins[3] has observed such an effect with DDT-resistant flies), adults and puparia from larvæ reared on a medium containing benzene hexachloride were analysed, using the colorimetric method described by Armstrong, Bradbury and Standen[2]. It was found, from two determinations on a total of 150 puparia and 150 female flies, that gamma-benzene hexachloride was present in the intact puparia to the average amount of 40 µgm./gm. fly and in the adults to 17 µgm./gm. fly. This is enough in the adult to account for the difference between that picked up by the resistant and non-resistant flies.

It may be argued from these results that: (1) resistance to gamma-benzene hexachloride by houseflies is not due to resistance to penetration of the insecticide; (2) a detoxification mechanism is unlikely in flies resistant to benzene hexachloride, since these carry over in their tissues from the larval stage enough insecticide to kill normal flies in a few minutes.

A detailed account of this work will appear elsewhere. We are indebted to our colleagues at Widnes Laboratory, Messrs. R. Hill, F. P. Johnson and C. Whimpenny, for the synthesis of benzene hexachloride from carbon-14-labelled benzene and the separation of the isomers by chromatography. Mr. H. Standen carried out the colorimetric analyses.

Unit Cell and Preliminary Structure for Cellulose Triacetate

Although interplanar spacings for cellulose acetate II have been published[1,2], I have been unable to trace a determination of the unit cell or space group.

Small films of highly crystalline triacetate with good fibrous orientation and a fair degree of biaxial orientation have been prepared by repeated rolling at successively higher temperatures between 160° and 215° C. The higher orientation was somewhat improved by swelling in glacial acetic acid, followed by drying at 110° C. while maintaining the sample under pressure. Figs. 1*a* and *b* are X-ray diffraction photographs of such films showing several new spacings. On the perpendicular photographs along the equator, there are reflexions with the spacings 24·50 and 12·25 A., and on the first level there is a 9·61-A. spacing. On the parallel photograph there is a faint 5·78-A. spacing along the equator. It can be seen that the fibre orientation is better in a plane containing the fibre axis and a perpendicular to the plane of the sheet, than in the plane of the sheet.

The additional data have made it possible to index all spots on the basis of an orthogonal unit cell containing four cellobiose hexa-acetate residues. The dimensions of this unit cell, taking [00*l*] as the fibre direction, are $a = 24·50$ A., $b = 11·56$ A. and $c = 10·48$ A. The theoretical density is 1·30 gm./c.c., and this compares with 1·29 gm./c.c. observed for a fairly well-crystallized sample. Thirty reflexions have been indexed on this basis, and all have spacings in agreement with those calculated to within 1 per cent.

The orthogonal cell and the symmetry of the photographs suggest a space group of the orthorhombic system. The (*h*00), (0*k*0) and (00*l*) reflexions, except for a weak (100), are apparently absent for *h*, *k* or *l* odd. The presence of (100) suggests the space group, $P22_12_1$, if the screw axes in the *b*- and *c*-directions are regarded as real. Other orthorhombic possibilities are $P222$, $P22_12$ and $P222_1$. All these space groups have a two-fold axis in the *a*-direction, but it appears to be impossible to set up a model with two pairs of cellulose chains related by such a two-fold axis and which will give rise to a weak (020) reflexion. It was therefore decided that cellulose triacetate is only pseudo-orthorhombic and the probable space group is $P2_1$, but that it may be closely approximated by $P2_12_12_1$.

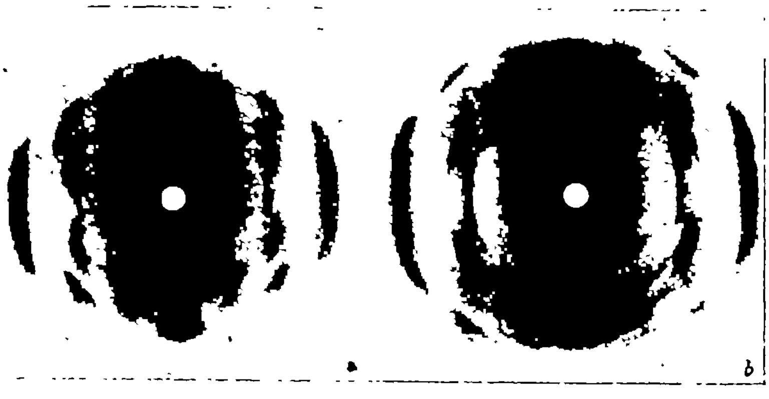

Fig. 1. X-ray diffraction pattern of highly oriented crystalline cellulose triacetate. Copper $K\alpha$ monochromatic radiation. (*a*) X-rays parallel to the plane of the sheet. (*b*) X-rays perpendicular to the plane of the sheet

In the case of cellulose I and II, the cellulose chains are necessarily coincident with the 2_1 axes, but this is not a requirement in this case. In one model based on $P2_12_12_1$, which gives promising agreement with the intensities, the cellulose triacetate chains are paired about a c_2-axis, with the planes of the glucose residues parallel to one another and inclined at about 45° with respect to *a*. The adjacent c_2-axes then have similar pairs of chains directed in the opposite direction and inclined at about $-45°$.

The intensities are quite sensitive to the positions of the acetyl groups, and a refinement of this model promises considerable structural detail which will be published elsewhere.

Production of Magnetic Fields in Liquid Mercury by Mechanical Motion

In connexion with recent attempts by Alfvén, Biermann, Batchelor *et al.*, to explain stellar and interstellar magnetic fields, we have considered the possibility of producing electric currents and magnetic fields in liquid mercury by suitable mechanical motion.

Our experiments are arranged as follows. In a cylindrical vessel filled with mercury we have rotated the upper half by means of a stirrer, while the lower half was prevented from rotation by means of radially fixed vanes on the bottom. The angular velocity of the mercury in the upper half was fairly high (about 20–35 c./sec.) and slowed down to zero in the lower part of the vessel. Accordingly, there exists a rotational and toroidal flow of liquid mercury. The present research is restricted to the action of the toroidal flow only. In the absence of any outer magnetic field, the electrons appear to go somewhat ahead of the ions, so that there results a toroidal electric current causing a circular magnetic field around the axis of rotation. We have succeeded in detecting this magnetic field and find a value of 10^{-4} gauss, which seems to fit reasonably well with theoretical expectations.

It may seem difficult to screen off the magnetic field of the earth to less than 10^{-4} gauss over the whole area involved. Indeed, using large Helmholtz coils and enclosing the whole apparatus in a box of suitable screening material, there still remained a field of the strength of some 10^{-4} gauss. But fortunately the effect described above can be separated quite simply from the influence of the earth's magnetic field, as the former increases with the square of the speed of rotation, the latter linearly. Reversing the sense of rotation causes the two effects to be added or to be subtracted. This easily enables the evaluation of the magnetic field-strength created within the circulating liquid. Details of the experiments will be communicated soon in the *Zeitschrift für Physik.*

The production of the magnetic fields can be easily understood, regarding the electrons as having a free mean path within the liquid mercury. The electrons will appear at any point *A* with a velocity they have gained from the last impact at a different point *B*. Whenever a circulating flow of a liquid has a velocity gradient which is not linear, as is often the case in pipes, etc., the diffusion of the electrons causes an electric current in the direction of the flow and accordingly a magnetic field. For a rotational motion, the electric field producing the current observed cannot be compensated by the Coulomb forces of any space charges.

Magnetic Fields measured within Flames brought mechanically into Rotational Motion

The flame of an oxygen burner was brought into spinning motion by forcing the gas tangentially into a cylindrical tube. The gas inlet is interrupted at frequent intervals in order to produce separate whirls of burning gas, which move along inside the tube one after the other. An induction coil surrounding the tube shows the existence of toroidal magnetic fields moving along together with (that is, surrounding) the plasma whirls. From the magnetic field we conclude that there exist electric currents within the plasma whirls accompanying the motion of the plasma.

Very careful experiments extending over several years show clearly that these currents can be attributed to the velocity difference of ions and electrons within each whirl. The electrons are retarded relatively to the ions because of their enhanced diffusion velocity into and back from cooler portions of the gas.

Quantitative measurements have been made in these experiments. From a determination of the temperature by several independent spectroscopic methods, the degree of ionization can be evaluated. An independent determination of the latter is obtained using the conductivity of the gas, which can also be measured and was found to reach values of the order of 10^{-11} e.s.u. if metallic potassium was introduced into the flame.

The induction coils were calibrated by means of a simple loop of wire, connected to an oscillatory device. For calibration the wire was put into the tube in place of the gas whirls. The measured toroidal magnetic field-strength created from the plasma whirls was found to be of the order of magnitude of 10^{-4} gauss.

The influence of magnetic fluctuations other than those created inside the tube was eliminated by using two identical coils connected in such a way that magnetic influence upon one coil only is to be registered. Compensation of the earth's magnetic field and application of an external field three times that of the earth causes only the zero level of our registration to shift up and down without altering the magnitude of the effects measured. Many other tests of the reality of the magnetic fields measured have been carried out.

Reduction of the speed of rotation causes the effect to decrease, becoming zero with no rotation at all. Decrease of the conductivity with less potassium added causes the effect to decrease likewise. Details of the experiments will be communicated in the *Zeitschrift für Naturforschung.*

The experiments described here and in the preceding communication deal with two different ways of creating magnetic fields within a 'plasma' by mechanical forces only. The first one deals with a plasma of practically zero compressibility, the latter with a compressible gas. In the latter, the experiments support the theory developed by Biermann and Schlüter[1] *et al.* and are obviously analogous to astrophysical phenomena.

Recovery of Isotopic Boron and Lithium from Nuclear Research Emulsions

Nuclear research emulsions are sometimes loaded with the stable isotopes of boron or lithium for work on nuclear disintegrations or on neutron counting by the photographic plate technique. Since the usual additions correspond to as much as 16 mgm. lithium or 23 mgm. boron per c.c. of emulsion, and these amounts of isotopes of low natural abundance are costly, the technique is expensive unless the isotope can be readily recovered after plate exposure.

Two series of spectrographic analyses have, therefore, been made on the solutions from the usual processing sequence on nuclear plates coated with 200 µ thickness of emulsion and loaded with natural lithium sulphate and boric acid respectively. It was found that pre-soaking for one hour in distilled water extracted 90 per cent of the boric acid, the remainder being found in the developer (50 min. development). In the case of lithium sulphate, two-thirds was found in the pre-soak, one-third in the developer and a small amount in the 10 per cent potassium bromide stop-bath (30 min.). There was no detectable boron or lithium in the remaining solutions or in the gelatin, so almost complete recovery can be achieved very simply from the pre-soak and developer solutions.

Crystal Structure and Magnetic Properties of Cobalt Ferrite at Low Temperatures

Cobalt ferrite ($CoO.Fe_2O_3$) and magnetite ($FeO.Fe_2O_3$) both crystallize at room temperature with the inversed-spinel-type of structure[1]. A magnetic transition consisting of an abrupt decrease of saturation magnetization takes place in magnetite[2] at 116° K., and is accompanied by a slight deformation of the structure cell from cubic symmetry above the transition to approximately rhombohedral symmetry below[3]. As cobalt ferrite[4] undergoes a similar magnetic transition at 90° K., we might expect that, like magnetite, it is no longer cubic below its magnetic transition temperature. We have shown by means of X-ray powder photography that this is indeed true, but the departure from cubic symmetry is even smaller than in the case of magnetite. Our results indicate that the structure cell of cobalt ferrite at low temperatures is approximately tetragonal.

Powder photographs were taken at liquid nitrogen temperature (80° K.) with a 19-cm. camera; both cobalt $K\alpha$ and iron $K\alpha$ radiations were employed. Several different specimens were prepared by mixing appropriate proportions of pure CoO and αFe_2O_3, and firing the mixture in air for several hours at 1,100° C. The departure from cubic symmetry was revealed by splitting of some of the high-order, originally cubic lines. The cubic 840 and 800 reflexions were each split into two components with intensities approximately in the ratio 2 : 1, in order of increasing Bragg angle. No splitting of the high-order 444 (iron $K\alpha$) and 555 (cobalt $K\alpha$) reflexions could be detected.

This behaviour indicates that there is a principal dilatation along a [100] direction, so that the structure cell is approximately tetragonal with c/a slightly less than unity. This interpretation requires 840 to be split into three tetragonal components (840, 804 and 408); but the first two of these are too close together to be resolved. In the accompanying table we give several independent values of c/a, deduced from measurements on split cubic reflexions. These values are in fairly good mutual agreement. In view of the extreme smallness of the lattice deformation, it would be of interest to study the line splitting in more detail by means of a sensitive counter spectrometer.

Cubic reflexion	Tetragonal indices	Wave-length	Value of c/a
800	800, 008	Iron $K\alpha_1$	0·99368
800	,,	Iron $K\alpha_2$	0 99370
840	840 $\begin{cases} 804 \\ 408 \end{cases}$	Cobalt $K\alpha_1$	0 99685

We believe that the X-ray results on Fe_3O_4 and $CoFe_2O_4$ at low temperatures are relevant to the interpretation of the low-temperature magnetic transitions. The changes of symmetry take similar forms to those observed in FeO and CoO respectively, as these monoxides are cooled below their antiferromagnetic Curie temperatures[5]. Thus FeO and $FeO.Fe_2O_3$ are both rhombohedral at low temperatures, with the rhombohedral angle α_R slightly less than 60°, and CoO and $CoO.Fe_2O_3$ are both tetragonal with c/a slightly less than unity. Verwey's theory[6] of the origin of the low-temperature transition in magnetite involves an ordering of the valency electrons in the octahedral sites. His model requires a low-temperature tetragonal symmetry, whereas the observed symmetry is more nearly rhombohedral. The observed low-temperature symmetry in cobalt ferrite is tetragonal, but Verwey's model cannot explain this as electronic interchange between Co^{2+} and Fe^{3+} is more or less inhibited. We conclude that Verwey's theory cannot explain the origin of the low-temperature transitions in either magnetite or cobalt ferrite. The correct solution may be found by considering the close similarity of their structural behaviour with that of the corresponding simple monoxides.

Formulation of the Velocity Constant in Chemical Kinetics

MUCH information on chemical kinetics has been accumulated in recent years. In many cases it is of high precision and of proved exactness, so that comparisons may be made with a fair degree of satisfaction of data presented for similar systems. Further, the exactness of some of the data makes it possible to use information obtained by different authors as a basis of further calculation. In view of these statements, it may be surprising to realize that the basic measurement in such studies, namely, the velocity or rate constant, lacks a logical and unique definition.

Existing definitions may be based on the rate of disappearance of reactants, or alternatively, on the rate of appearance of products. Even if one attempts to maintain a consistent definition based on reactants, difficulties arise. For example, a reaction step which may be written kinetically as:

$$2A + B \rightarrow X, \qquad (1)$$

where A, B and X are atoms, radicals, or molecules, may define two velocity constants as follows:

$$-\frac{d(A)}{dt} = k_1(A)^2(B)\,; \quad -\frac{d(B)}{dt} = k_2(A)^2(B). \quad (2)$$

Since the rate of removal of A is clearly twice that of B, it follows that $k_1 = 2k_2$, the concentrations of the reactants being expressed in common units. Thus, to assess the precise meaning of such a velocity constant, it is necessary to examine carefully any kinetic analysis which has been attempted. This applies also to a definition based on products.

It is here suggested that the velocity constant should be based not on reactants or products, but on the intermediate complex formed. Thus in the above example, the intermediate complex would have the formula A_2B, so that the rate at which units of reaction occur would be $k_3(A)^2(B)$, that is, rate at which two molecules of A react with one molecule of B to form one molecule of X. With this definition, it is now possible to write:

$$-\frac{d(A)}{dt} = 2\,k_3(A)^2(B)\,; \quad -\frac{d(B)}{dt} = k_3(A)^2(B). \quad (3)$$

This simplification of the formulation of the velocity constant is of importance in the case of a reaction involving, say, the mutual destruction of two radicals, a process well known in many chemical studies. For example:

$$A + A \rightarrow A_2 \quad k_4 \qquad (4)$$
$$A + B \rightarrow AB \quad k_5. \qquad (5)$$

Using the suggested system,

Rate of reaction (4) $= k_4(A)^2$;

$$-\frac{d(A)}{dt} = 2\,k_4(A)^2.$$

Rate of reaction (5) $= k_5(A)\,(B)$;

$$-\frac{d(A)}{dt} = -\frac{d(B)}{dt} = k_5(A)(B).$$

These reactions are of similar type and therefore it is of interest to compare the values of k_4 and k_5; but first it must be remembered that these velocity constants contain a collision number—the rate of collision for reactants at unit concentration. These collision numbers Z_4 and Z_5 differ by a factor of 2 (changes in collision cross-section and mass being usually a second-order change), as derived from the classical kinetic theory:

$$Z_4 = 2\sqrt{\pi}\,N_A^2 d_A^2\sqrt{RT/M_A}$$

$$Z_5 = 2\sqrt{2\pi}N_A N_B\left(\frac{d_A + d_B}{2}\right)^2 \sqrt{\frac{M_A + M_B}{M_A M_B}\,.\,RT}.$$

Thus it will be seen that the best comparison of the two processes must recognize that $Z_5/Z_4 \sim 2$. The comparison is most easily achieved by referring to the appropriate collision efficiencies, since the collision efficiency is defined as being equal to k/Z.

Theoretical calculations of rates of chemical reaction almost invariably involve the velocity constant in the sense suggested here, and it is proposed that experimental values should be brought into line logically in the manner discussed above.

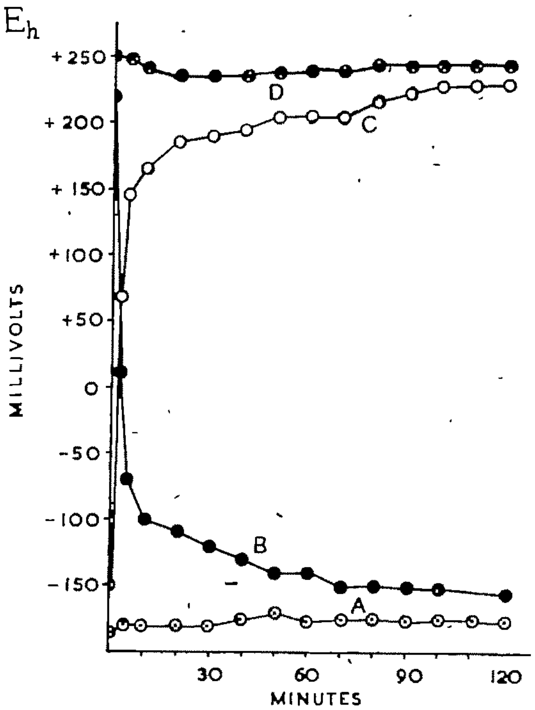
Time-Lag in E_h Potentials

ELECTRODE potentials are measured in order to indicate the state of the electromotive equilibrium of bacterial cultures; equilibrium depends on the activity between the cellular enzymes and the constituents of the medium. It is generally agreed that methods of measurement are still empirical. For rapidly growing cultures Hewitt[1] suggests half-hourly readings; but it may not be realized that with the usual method[2] the recorded readings do not represent the true E_h at the time of measuring. This can be shown by the following experiment in which an electrode is subjected to rapid changes in E_h.

Two identical electrodes were used: one was continuously immersed in a medium of a given E_h, and the other was brought into this medium, having previously been kept at a different E_h level. The change-over was effected without exposing the surface of the electrode to air. A low E_h system was obtained by autoclaving a 1 per cent peptone solution of pH 7·6 containing 0·25 per cent sodium thioglycollate. This solution was placed in a wide test-tube, forming a column of about 5 in. A small glass tube filled to the rim with the same medium, but without the reducing agent, was suspended by wire above the larger tube. Mercury–platinum electrodes (20 s.w.g. platinum wire, 15 mm. exposed length) were placed into each tube, and after a lapse of two hours to allow for stabilization, readings were taken. The electrode continuously immersed in the reduced system is labelled A in the diagram. The small tube carrying electrode B was then lowered below the surface. The small tube was carefully removed without mixing, and electrode B was placed alongside A. The lag in registering the sudden alteration in the E_h leve is well shown. The small admixture of peptone wate in the process of transfer did not appreciably alter the E_h as shown by electrode A.



The reverse experiment was also performed wit substantially the same results. The reduced syste was placed in the small tube (electrode C) and the peptone solution in the large tube (electrode D).

It is clear that a true E_h reading is not obtaine within two hours. This is a particularly seriou source of error when the behaviour of bacteria cultures is followed. On account of the lag, the initia fall is, in fact, steeper than one would be led to believe When continuous readings are taken of rapidly alter ing biological systems, this lag, which is inherent i the method, should be considered.

A Sealed-off Cathode-Ray Tube with a Very High Writing Speed

AN experimental cathode-ray tube of the sealed-o type has been constructed for the purpose of visu observation and photographic recording of no recurrent high-voltage transient phenomena, wit sweep speeds in the milli-microsecond range.

This tube is of the 6-in. flat-faced type, and ha an aluminized screen with a highly actinic blue pho phor. The beam is magnetically focused and electr statically deflected. An incoming signal is fed int

a straight twin-wire transmission line which passes through the tube in a direction perpendicular to the tube axis, and which forms the vertical deflector system. This design considerably reduces the transit time of the electron beam in the deflector field and, at the same time, enables the deflector system to be correctly matched with the signal generator and connecting system. The low-frequency deflexion sensitivity was found to be 0·006 mm. per volt at a beam-accelerating voltage of 25 kV.

The performance of the tube is illustrated in Fig. 1, which is a photograph of a 9,500-Mc./s. oscillation displayed on a single sweep time-base of 1·3 mμsec. duration. It is of interest to note that in this photograph the writing speed of the electron beam at the screen phosphor has a maximum value of about 4×10^{10} cm. per second (1·3 *c*) with a trace width of 0·2 mm. Fig. 2 shows an oscillation of the same frequency but with an increased amplitude and a maximum writing speed of $6 \cdot 6 \times 10^{10}$ cm. per second (2·2 *c*) with a trace width of the order of 0·5 mm. The original oscillograms were not suitable for reproduction here, but the trace could be clearly seen and measured. The records suggest that under these conditions of operation, with the tube in its present form, the useful horizontal sweep is limited to about 4 cm. because of defocusing. The photographs were taken with a Wray *f*1 copying lens on Ilford 5G91 film, developed in Johnson's Contrast developer and printed on Ilford Grade 5*B* paper.

An improved version of the tube is now being prepared, and it is anticipated that a further advance on the writing-speed performance will be made. Further investigations are also being carried out to determine the ultimate writing speed of various screen phosphors.

More complete details of design and tube performance and of the milli-microsecond time-base circuit will be published elsewhere.

Saw-toothed Wave-forms in Sound

Using an improved form of apparatus previously described by Timbrell[1], one of us (T. F. W. E.) has found certain anomalies in the rate of distortion of sound pulses of finite amplitude propagated in air contained in a wide tube. This communication is concerned with the behaviour of those sound pulses of finite amplitude in which the leading half-cycle of the wave is one of rarefaction. This type of waveform could be formed in either of two ways: (*a*) by direct generation at a loud-speaker placed at one end of the propagation tube, or (*b*) by the reflexion of a leading compression pulse (generated by the loud-speaker) at the end of the tube when it is open to the atmosphere—the back-travelling pulse will have a leading rarefaction due to phase-change at reflexion.

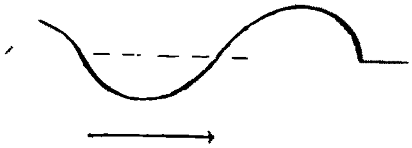

Fig. 1. Pressure–time curve of a sinusoidal pulse with a leading rarefaction

Stokes[2] predicts that a rarefaction wave train as in Fig. 1 will become distorted during propagation in such a way that the rarefaction and compression peaks will approach each other. The central region will correspondingly become steeper and the head and tail regions less inclined, and ultimately a discontinuity or shock will be formed (see Fig. 2). The rate at which this process of distortion takes place may easily be calculated from a knowledge of the pressure or particle-velocity amplitudes in the wave. We have found that the observed experimental value of the decay confirms the rate predicted by Stokes's theory only when the wave is generated by method (*a*) above.

If a continuous wave-form of initial rarefaction is generated by method (*b*), it is found that it does not contain any discontinuity in its central region after such a time that a shock should be present according to Stokes's theory. It is, in fact, still approximately sinusoidal (see Fig. 3). More detailed measurements by one of us (T. F. W. E.) have shown that the wave does suffer distortion throughout its propagation away from the open end of the tube but at a much reduced rate.

This anomalous behaviour may be attributed to the process of reflexion at an open end. The process is too complex to be analysed in any detail here; but briefly (see also a recent paper by Chester[3]), the reflected wave is to be regarded as the superposition of a large number of singly and multiply diffracted and reflected waves formed by the edges and walls of the

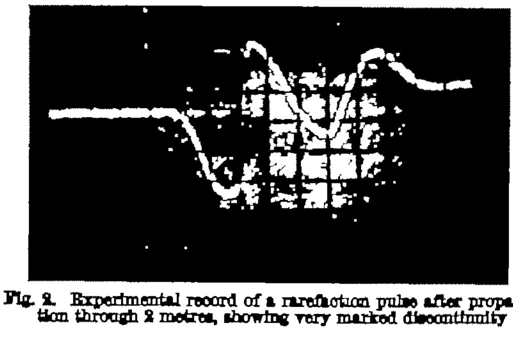

Fig. 2. Experimental record of a rarefaction pulse after propagation through 2 metres, showing very marked discontinuity

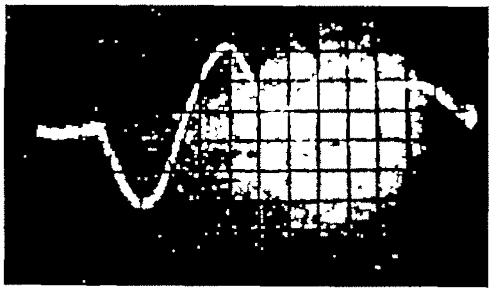

Fig. 3. Rarefaction pulse formed by method (*b*) measured at 2 metres from open end

tube near its open end. Even some distance along the propagation tube from the open end, the many wavefronts of these secondary waves are not perpendicular to the tube axis and are still altering their relative orientations. Only at an infinite distance from the open end does the reflected wave system become geometrically stable, and only then is it permissible to compare the experimental results with theory.

So far as is known, the occurrence and behaviour of sound pulses of finite amplitude in which the first half-cycle is one of rarefaction have not previously been recorded in the literature. The reflexion of a compression pulse at any boundary of decreasing acoustic impedance will give rise to a wave of the type described here; for example, an underwater explosion reflected from the free surface of the water. It also seems probable that such a rarefaction pulse might be formed as a result of cavitation phenomena.

Sequential Sampling in Biological Assay

In an investigation relating to the isolation and purification of chorionic gonadotrophin from pregnancy urine, the following problem has arisen: "Does fraction *A* contain at least the amount *X* of chorionic gonadotrophin?" It was necessary to answer this question in the shortest possible time and to use as little material of *A* as possible. As the solution of this rather specialized problem may have a much more general application to researches of similar nature, it is felt to be worth communicating.

For simplicity, arbitrary concrete figures will be given in the following. Substance *A* was to be tested for the hypothesis that its chorionic gonadotrophin content was equal to or greater than 100 I.U. per mgm.; if so, it was to be accepted; if it contained less than 100 I.U./mgm. it was to be discarded. The tolerated risks with regard to the precision of the estimate were fixed at 80–125 per cent, and with regard to the probability of making a wrong decision were allowed to be 5 per cent, no preference being given to either errors of the first or second kind. That is to say, only in five out of two hundred cases would the substance be rejected if it contained 125 or more I.U. chorionic gonadotrophin/mgm., and in only five out of two hundred cases would it be accepted although it actually contained 80 or less I.U./mgm.

In principle, the problem thus defined is a common one in sampling inspection, and a sequential test[1] seemed most likely to meet the requirements. In the present case the problem is complicated, since no chemical method is suitable and a biological assay method has to be adopted; the spermiation test utilizing male toads[2] was chosen.

To solve the problem as stated above, substance *A* was assumed to contain 100 I.U. chorionic gonadotrophin/mgm., and the median effective dose (*ED* 50), according to this assumption, was injected into male toads (*Bufo viridis*). The toads were taken at random from a population the dose-response curve of which for chorionic gonadotrophin had been established not more than one month before. This seemed justifiable in view of the fact that the slope of the regression line (plotting probit of percentage reactors against log dose) had remained constant within sampling error over a period of two years, and no significant shift of the regression line was ever observed within a period of up to five weeks[3]. The percentage of expected non-reactors (that is, toads with no spermatozoa in their urine 3 hr. after the injection), when given 80 and 125 per cent respectively of the *ED* 50, was read off the regression line and was found to be 73 and 27 per cent respectively. Thus, in terms of a sequential test—adopting Wald's[1] notation, p denoting the fraction of non-reactors—the following values were obtained: $p_0 = 0{\cdot}27$, $p_1 = 0{\cdot}73$, the probability of committing an error of the first (α) or second (β) kind being $\alpha = \beta = 0{\cdot}025$. Consequently, the hypothesis, that the toad population subsequent to the injection of what was assumed to be the *ED* 50 consisted of 50 per cent or more reactors, was tested against the alternative hypothesis that it contained less than 50 per cent reactors. Thus the test showed whether the dose of chorionic gonadotrophin each toad had received was, in fact, equal to or greater than *ED* 50, and consequently, whether the amount contained in substance *A* conformed to the requirements for its acceptance.

The actual test was carried out according to standard sequential sampling procedures. Acceptance and rejection numbers were calculated, and the test was terminated as soon as the number of non-reactors agreed with either the acceptance number or the rejection number. Furthermore, to arrive at a decision within 24 hr., grouping was adopted (four toads being tested at a time), and the test was truncated if no decision was obtained after the eighth sample (that is, after a total of thirty-two toads had been injected and inspected 3 hr. afterwards). Calculation of the average sample number function showed that, on the average, a decision was to be expected after one to four samples, depending on the amount of chorionic gonadotrophin actually contained in the test substance. The actual results were consistent with these theoretical expectations.

Several points, for example, the most practical grouping, the effect of truncation on the probability of making a wrong decision, etc., are still under examination. The results of these investigations will be published in more detail elsewhere.

Family Antigens or 'Private' Blood Groups and the Sub-Group of A–A_4

Family antigens or 'private' blood groups are defined by Levine[1] as being "characterized by the positive or negative reactions being limited to members of a particular family".

Levine reviewed five such antigens, van Loghem and van der Hart[2] have reported a sixth and Holman[3] a seventh, and others are often discussed among blood-group workers. Recently, Chown[4] pointed out how the literature might have received the report of yet another 'private' blood group had not a search been made among bloods of races other than that race in which the antibody occurred. In Chown's case, a North American Indian woman had an antibody against her husband's red cells but it failed to react with the red cells of 794 other Indians. However, when the serum was used against red cells from Caucasians, it was shown to be *anti-Kell*.

Chown, considering a recent lecture[5] on the sub-groups of A, has suggested my directing the attention of other blood-group serologists to another possible fallacy.

Mr. J. had given blood on many occasions and had been regularly reported as group O. He was considered as such when a hospital reported to these laboratories that his blood was incompatible with the serum of a Miss R., a nullipara without transfusion history. Mr. J.'s cells were tested with anti-A and anti-B with no reactions occurring; his serum agglutinated both pooled A and pooled B cells, that is, he was regrouped as O. Miss R.'s serum strongly agglutinated Mr. J.'s cells, his father's and one of Mr. J.'s children. Attempts were made to identify the antibody in Miss R.'s serum by testing it against several hundred group O bloods, all of which were compatible.

Samples of Mr. J.'s blood and Miss R.'s serum were sent to other blood-group workers and they confirmed Mr. J. as group O and his cells to contain a unique antigen—the Jackson antigen—to which Miss R. had the antibody. The paper was prepared for publication, and what appeared to be a clerical error in the protocols necessitated the examination of further specimens from Mr. J. and his children.

Since first testing Mr. J.'s blood with Miss R.'s serum, the method of ABO grouping had been altered in these laboratories. A precipitin tube technique had always been used, and the serum tested against pooled A and pooled B cells. However, as an additional check we started testing the red cells with group O serum. This additional test revealed a blood which gave the following reaction:

Red cells			Serum		
Anti-A	Anti-B	Anti-AB (Group O)	A cells	B cells	O cells
−	−	++	+	+	−

It will be seen that without the use of group O serum this blood would have been classified as group O. Subsequent tests showed that this blood was of the type A_4 described by Gammelgaard and Marcussen[6]. Fuller reports[4] on these bloods have been published elsewhere, but briefly they (1) give little or no reaction with anti-A sera; (2) are agglutinated by all group O sera; (3) their sera contain an agglutinin against A_1 and A_2 cells strongly active at 20° C., in addition to anti-B.

On receiving the requested specimens from Mr. J. and his children, they were tested fully for all red cell antigens, and in ABO grouping their red cells were tested with group O serum. Surprisingly, the cells of Mr. J. and one of his children gave strong agglutination with group O serum. They were soon confirmed as A_4 and it was realized that Miss R.'s serum contained no unique antibody and that the testing of hundreds of group O bloods had not been the search for the so-called "Jackson antigen" but for another A_4, the occurrence of which among British people is about 1 in 30,000.

It is strongly recommended that: (1) all so-called family or private blood groups be tested with group O serum (in the course of investigations the Levay[7] and Graydon[8] bloods have been tested with group O serum, and these are not A_4 bloods); (2) group O serum is an essential reagent in ABO grouping; (3) the racial origin of both the donor of the family antigen and the corresponding antibody be considered (in reporting the latest family antigen—the Wright antigen—Holman[3] failed to consider the racial origins of the family); in this respect, Shapiro[9] has reported A_4 bloods as common among Bantus, and Caucasian × Bantus mating could well lead to a similar set of circumstances to Chown's but involving the A_4 antigen and not the *Kell*.

My thanks are due to Dr. C. C. Bowley, director of these laboratories, for permission to publish this communication.

Sea Foam

In a recent article[1] on the persistent sea foams that may be cast up on the shore during stormy weather, Miss E. C. Pope has suggested that protein debris from damaged planktonic organisms and alginates from sea-weed may be responsible for the formation and stability of the foam.

The late Prof. J. H. Orton was much interested in the phenomenon of sea foam, and wondered if considerable amounts of plankton and organic debris might not be brought ashore by this means (and by wave-action in general) to form a source of food for limpets and other intertidal animals. At his instigation I made a few preliminary observations on sea foam; the results may be of interest in comparison with the Australian observations.

Samples of the foam cast up on the shore at Kallow Point, Port St. Mary, Isle of Man, in December 1948 and April 1949, were collected in screw-topped jars and allowed to settle for 24 hr. It was found that 0·5 litre of foam reduced to 5 c.c. of an opalescent yellow-brown fluid, which deposited flocculent brown particles on standing, and had a typical 'shore' smell, similar to that of sponges and sea-weed. Microscopical examination of the fluid showed the presence of particulate matter of various sizes. Of the few recognizable particles, some were of obvious planktonic origin, for example, parts of copepod cuticle, diatom frustules, and green flagellates, but others were of littoral or benthic origin, such as sponge spicules, foraminiferan shells and algal fragments. However, the majority of the particles were unrecognizable, varying from 0·5 to 10 µ in diameter, but mostly about 1 µ (that is, of just colloidal dimensions), and showed a strong tendency to form a layer at air/water interfaces.

After drying at 105° C., 4 c.c. of the residual fluid reduced to 0·17 gm. of total solids, of which 0·135 gm. was due to the salt present in the water, leaving 0·035 gm. of other solids probably corresponding to the particulate matter. The dried residue was tested for cellulose, protein and pentose with negative results. Both protein and pentose (among other substances) can produce stable foams by adsorption in the form of a rigid interfacial layer; but since this layer need be of only molecular thickness, the amount of stabilizing material does not have to be very large, and might remain undetected by the methods used. However, it was obvious that the food content of the foam was negligible compared with that already available on the shore.

While the evidence obtained was partly in support of Miss Pope's suggestions[1], there was no evidence that the apparent stabilizing particles were derived from living organisms broken up by the waves: they might have originated from detritus or fæcal matter. Furthermore, it does not seem essential to postulate the presence of a substance causing marked lowering of the surface tension. The properties associated with foam formation appear to be surface rigidity and a sharp rise in surface tension when the surface area is increased, rather than low surface tension by itself[2]. It is possible that the drag of the wind on the water compressing the surface film and causing it to 'solidify' is a contributory factor towards the formation of foam.

I am indebted to Dr. D. J. Crisp for advice on this matter.

Wave Riding of Dolphins

PREVIOUS discussions[1] of the wave riding of dolphins have been based on the assumption that it was necessary for a dolphin to have a weight greater than that of the displaced water in order to be able to ride a wave while totally immersed. It is the purpose of this communication to clarify this point and to show that it is the total weight of the dolphin which is significant rather than the excess weight.

From the hydrodynamic point of view, it is most convenient to consider the steady-state case in which the dolphin and the wave are stationary and the main body of water is moving with the wave velocity. Within the linearized theory of steady waves, streamlines of the flow are lines of constant pressure, and this relation may be expected to hold approximately for any steady-wave system. The simplest correct approximate way of computing the ideal force on an immersed body in such a flow is as a buoyant force, equal to the volume times the pressure gradient evaluated at the centre of the immersed volume. This pressure gradient equals the fluid density times ($g \cos \theta + u^2 K$), where u is the local velocity of the flow and θ and K are the inclination and curvature of the streamline, and this gradient is directed normal to the streamline. This buoyant force is opposed by the force $W \cos \theta - L$ (see Fig. 1), where W is the total weight of the immersed body and L is the hydrodynamic lift. This gives the relation

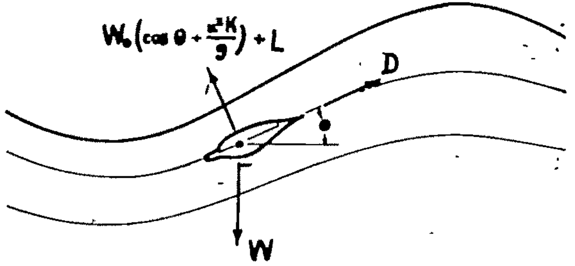

Fig. 1. Dolphin in a wave

$$L + \frac{W_0}{g} u^2 K = (W - W_0) \cos \theta, \tag{1}$$

where W_0 is the weight of the displaced fluid, the hydrostatic buoyant force on the body. Balance of forces in the direction of the streamline gives:

$$D = W \sin \theta, \tag{2}$$

where D is the hydrodynamic drag. For a wave rider planing on the surface, the equations would be the same but with $W_0 = 0$. The force opposing the hydrodynamic drag is independent of any buoyant force, which only affects the amount of hydrodynamic lift needed. Thus it is the total weight which is significant, and not the excess weight. The totally immersed dolphin may be at a slight disadvantage over a surface wave rider because the maximum value of θ is less below the surface than on the surface. However, the dolphin is at a significant advantage because it has very much less hydrodynamic wave drag and drag due to lift.

An alternative method of calculating the forces in this case would be to separate mathematically the effect of the gravitational field. From this point of view the drag force is opposed by a force equal to the displaced mass of fluid times the space derivative $u \, du/ds$ of $\frac{1}{2}u^2$ along the streamline, in addition to a force $(W - W_0) \sin \theta$. In view of the relation $g \sin \theta = u \, du/ds$, the two approaches may be seen to be equivalent. A third equivalent point of view is that an immersed body with no excess weight would be acted upon by a force which would give *it* the same acceleration as the fluid in the same vicinity.

For fore-and-aft stability the dolphin must be in a part of the wave for which K is positive, and it may be expected that this is normally the case. The hydrodynamic lift is thus generally somewhat less than $(W - W_0) \cos \theta$ and may be zero or of either sign.

In any event, the practical difficulty discussed by Woodcock and McBride, the difficulty of having to assume laminar flow, disappears. Added significance is given to their remark that this wave-riding force should be taken into account in any estimate of the dolphin's capacity for sustained work. With moderate velocities and reasonably large wave inclinations, the dolphin has amply sufficient thrust from this source to overcome drag with turbulent flow.

The opinions contained in this communication are the private ones of the writer and do not necessarily reflect the views of the United States Navy.

Physical Society, Acoustics Group (at the Science Museum, South Kensington, London, S.W.7), at 5.15 p.m.—Prof. R. J. Pumphrey and Mr. L. A. Tumarkin: "Theory of Hearing".

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. J. J. H. Hastings: "Problems of Biochemical Engineering".

Institution of Mechanical Engineers, Automobile Division (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. P. P. Love, Mr. P. G. Forrester and Mr. A. E. Burke: "Function of Materials in Bearing Operation".

Institution of the Rubber Industry, London Section (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. H. P. B. Edwards: "Cyclised Rubber"; at 7 p.m.—Mr. F. R. Horridge: "Collection, Grading and Packing of Rubber in Malaya".

Royal Society of Medicine, Experimental Medicine and Therapeutics Sections (at 1 Wimpole Street, London, W.1), at 5.30 p.m.—Prof. J. H. Gaddum: "Clinical Pharmacology" (W. E. Dixon Lecture).

University of London (in the Anatomy Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. Otto Koehler: "Thinking Without Words".*

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. L. Størmer (Oslo): "The Trilobitomorpha" ("Trilobites and Merostomes, an Old Arthropod Stock," 1).* (Further Lectures on December 9 and 11.)

Royal Institute of Chemistry (joint meeting with the Sir John Cass College Chemical Society, at the Sir John Cass College, Jewry Street, London, E.C.3), at 6 p.m.—Dr. H. Lester Smith: "The Manufacture of Antibiotics".

Wednesday, December 9

Physical Society, Colour Group (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 2.30 p.m.—Symposium on "The Colour-Rendering Properties of Fluorescent Lamps".

Royal Sanitary Institute (at 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Discussion on "Investigations into Detergency in Kitchens and Laundries".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. E. G. Woodroofe: "The Seed Crushing Industry".

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Symposium on "Vibration Methods of Testing".

Society of Chemical Industry, Corrosion Group (joint meeting with the London Section of the Oil and Colour Chemists' Association, in the Lecture Theatre of the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. J. E. O. Mayne and Mr. D. Van Rooyen: "The Mechanism of the Inhibition of Corrosion by Paints, with special reference to the action of Basic Pigments"; Mr. D. M. Brasher, Mr. A. H. Kingsbury and Mr. F. Wormwell: "Electrical Measurements in the Study of Paint Coatings on Metal".

Society of Chemical Industry, Food Group—Nutrition Panel (in the Rooms of the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W.1), at 6.30 p.m.—Dr. R. Passmore: "Some Recent Investigations of Human Calorie Requirements" (Nutritional Reappraisals—2).

Society of Public Analysts and Other Analytical Chemists, Polarographic Discussion Panel of the Physical Methods Group (at the Sir John Cass College, Jewry Street, London, E.C.3), at 6.45 p.m. —Annual General Meeting, followed by Mr. D. J. Ferrett: "Studies with the Rotating Platinum Cathode"; Mr. G. F. Reynolds and Mr. H. I. Shalgosky: "The Polarographic Determination of Indium in Zinc and Zinc-Base Alloys".

Thursday, December 10

Physical Society, Optical Group (at the Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 2.30 p.m.—Mr. G. H. Manville, Mr. M. G. L. Curties and Mr. H. W. Yates: Papers on "The Construction of Optical Elements".

Institution of British Agricultural Engineers (at the Smithfield Show and Agricultural Machinery Exhibition, Richmond Hall, Earls Court, London, S.W.5), at 3 p.m.—Dr. G. W. Cooke: "Designs of Fertilizer Distributors and their Mechanisms".*

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Francis Walshe, F.R.S.: "The Contribution of Clinical Observation to Cerebral Physiology" (The Ferrier Lecture).

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Mr. J. F. Grandy: "The Development of the St. Lawrence Waterway" (Neil Matheson McWharrie Lecture).

Physical Society, Low Temperature Group (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Eighth Annual General Meeting; 5.30 p.m.—Mr. A. G. Mackie: "The Performance and Operation of Low Temperature Rectifying Columns".

Sir Thomas Middleton Memorial Trust (in the Beveridge Hall, University of London, Senate House, London, W.C.1), at 5.30 p.m.—Prof. Sir James Scott Watson: "The State and Agriculture" (First Middleton Memorial Lecture).*

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. Henry Foy: "The Influence of the Intestinal Flora on the Synthesis of Hæmopoietic Factors in the Megaloblastic Anæmia of Africans".

British Sociological Association (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 8 p.m.—Mr. Ritchie Calder: "East Meets West".

Friday, December 11

Association of Applied Biologists (in the Mining Lecture Theatre, Imperial College, Prince Consort Road, London, S.W.7), at 11 a.m.—Scientific Papers.

British Society of Rheology (at the Institute of Physics, 47 Belgrave Square, London, S.W.1), at 2 p.m.—Symposium on "Methods of Presenting Rheological Results and Their Relations".

Society of Public Analysts and Other Analytical Chemists, Biological Methods Group (joint meeting with the Pharmaceutical Society, in the Anatomy Lecture Theatre, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Symposium on "The Assay and Detection of Pyrogens".

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—"Practical Training in Industry for the Graduate in Mechanical Engineering": four short papers by Mr. K. R. Evans, Mr. H. W. Fulton, Mr. R. S. Medlock and Prof. J. A. Pope.

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Dr. C. I. Bliss (U.S.A.): "Determinations of Drug Potency in Man".*

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. Ralph W. G. Wyckoff, For.Mem.R.S.: "The Electron Microscope in Biology".

Saturday, December 12

Biochemical Society (in the Department of Biochemistry, The London Hospital Medical College, Turner Street, London, E.1), at 11 a.m.—Scientific Papers.

British Mycological Society (at the Linnean Society of London, Burlington House, Piccadilly, London, W.1), at 12 noon—Annual General Meeting; 2.30 p.m.—Prof. C. T. Ingold: "Fungi and Water".

British Psychological Society (in the Psychology Department, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Dr. W. D. Neff: "Neural Mechanisms of Auditory Discrimination".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Physicist (with degree or equivalent qualification, and preferably with research and/or industrial experience) for work which is concerned with various aspects of the manufacture and properties of knitted products—The Secretary, Hosiery and Allied Trades Research Association, 4 First Avenue, Sherwood Rise, Nottingham (December 12).

Lecturer (with degree in electrical engineering and able to teach up to final degree standard) in Electrical Engineering—The Principal, Wigan and District Mining and Technical College, Wigan (December 14).

Analyst (with degree or equivalent qualification in chemistry, and preferably with some knowledge or interest in agriculture) to undertake and supervise routine soil and crop analyses—The Secretary, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (December 18).

LECTURER (with experience in industry and some knowledge of electrical measurements, servomechanisms and electronics) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING, University of Adelaide—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Adelaide, December 21).

ASSISTANT KEEPERS (2), at the Science Museum, South Kensington, S.W.7, (*a*) (with first- or second-class honours degree in engineering or aeronautical science) IN THE DEPARTMENT OF AERONAUTICS AND SAILING SHIPS; (*b*) (with first- or second-class honours degree in electrical engineering) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING AND COMMUNICATIONS—The Secretary, Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.134/54 (December 23).

CHEMIST (with honours degree in chemistry or A.R.I.C.) at Northern Outfall Works, Beckton, London, E.6—The Medical Officer of Health (PH/D 1), The County Hall, London, S.E.1 (December 28)

SCIENTISTS (with first- or second-class honours degree or equivalent qualification in physics or engineering, and some postgraduate experience in either light engineering, pneumatic and/or hydraulic mechanism design, design of light electrical, electronic or optical mechanisms) at the National Coal Board Central Research Establishment, Isleworth, Middlesex, to work in a group studying methods of establishing suitable instrumentation for use in mines and to design and improve instruments required for use in all aspects of mining and research into mining techniques—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/709 (December 28).

LECTURER IN BIOCHEMISTRY at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (December 31).

PRINCIPAL or SENIOR SCIENTIFIC OFFICER (with good honours degree in geography or equivalent) for physiographical and complementary ecological investigations in Great Britain, including work on problems of coast erosion and accretion; SENIOR SCIENTIFIC OFFICER or SCIENTIFIC OFFICER (with good honours degree in botany, agriculture or equivalent) to take charge of the Nature Conservancy Field Station, Moor House Nature Reserve, Alston; SCIENTIFIC OFFICER (with good honours degree in zoology, and preferably interested in small mammals) to assist with field studies and surveys of mammals in relation to the ecology of woodlands, at the Nature Conservancy Research Station, Grange-over-Sands, Lancashire—The Establishment Officer, The Nature Conservancy, 91 Victoria Street, London, S.W.1 (December 31).

PROFESSOR OF PHYSIOLOGY, PROFESSOR OF ZOOLOGY, and a LECTURER IN EXPERIMENTAL PHYSICS—The Secretary, University College, Cork, Ireland (January 4).

IMPERIAL CHEMICAL INDUSTRIES FELLOWSHIP, tenable at Durham or Newcastle, for research in chemistry, physics and allied subjects, including the biological application of chemistry—The Registrar, University Office, 46 North Bailey, Durham (January 9).

TURNER AND NEWALL FELLOWSHIP, tenable at Durham or Newcastle, for research in engineering, inorganic chemistry or physics, or in an allied science, if approval for the purpose of such an award is obtained—The Registrar, University Office, 46 North Bailey, Durham (January 9).

SENIOR LECTURER IN APPLIED AND INDUSTRIAL CHEMISTRY, a LECTURER IN CIVIL ENGINEERING, a LECTURER IN CHEMISTRY, and LECTURERS (2) IN PHYSIOLOGY, at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Cape Town, January 25).

LECTURER or ASSISTANT PROFESSOR OF ZOOLOGY—The Dean, Faculty of Arts and Science, University of Alberta, Edmonton, Canada (February 1).

ASSISTANT LECTURER (Grade B) IN PHYSICS—The Principal, Royal Technical College, Salford.

BIOCHEMIST (Senior grade) for duties in the Department of Clinical Pathology—The Group Secretary, Stafford Hospital Management Committee, 13 Foregate Street, Stafford

CHEMICAL ENGINEER or APPLIED CHEMIST (preferably with industrial experience) required for a new Industrial Advisory Service—The Coal Tar Research Association, Oxford Road, Gomersal, Leeds

LECTURER or ASSISTANT LECTURER IN ANIMAL PHYSIOLOGY in the Department of Zoology—The Secretary and Registrar, The University, Southampton.

LECTURER or ASSISTANT PROFESSOR OF APPLIED MATHEMATICS—Prof. I. R. Pounder, Department of Mathematics, University of Toronto, Toronto, Canada.

RESEARCH ASSISTANT (with a degree in engineering or physics) at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, to carry out research on heat transfer, refrigeration or aerodynamics—The Clerk to the Governors, Borough Polytechnic, Borough Road, London, S.E.1.

NATIONAL SOVEREIGNTY, THE CONTINENTAL SHELF AND MARINE RESEARCH

MARINE biologists and oceanographers have greatly benefited by the legal doctrine of the freedom of the seas. In times of peace they have been able to work wherever scientific needs dictated. However, since 1945 there has been a flow of unilateral declarations concerning sovereignty over the continental shelf, which boded ill for the future of international marine research in the areas concerned. The proclamations have arisen mainly from the urge to obtain oil from beneath the shelf. The International Law Commission of the United Nations has now considered, at great length, the regime of the high seas, and has agreed to recognize qualified sovereign rights of a coastal State over the adjacent part of the continental shelf as far as the 200-metre contour. The implications are far-reaching. The Commission's recommendations should be carefully examined before they come up for consideration by the General Assembly.

The position was ably stated by Dr. A. E. Moodie, of the Department of Geography, Birkbeck College, London, at a joint meeting of Sections C (Geology), D (Zoology) and E (Geography) of the British Association during the recent Liverpool meeting, an account of which appears on p. 1070, together with later information on the subject. All waters contiguous to a coast will be divided into two zones. First is the 'territorial sea', replacing the older 'territorial waters' lying between low-water mark and the three-mile (or x-mile) limit; within it full sovereign rights will be exercisable. The territorial sea will not be further discussed here. But secondly, there is the continental shelf, legally extending from the limit of the territorial sea to the 100-fm. or 200-m. contour at the edge of the shelf

The recommendations are presented as a series of eight draft articles in the "Report of the International Law Commission covering the Work of its Fifth Session" (United Nations: General Assembly, Publication *A/CN.4/76*, August 17, 1953). They are:

(1) As used in these articles, the term 'continental shelf' refers to the sea-bed and subsoil of the submarine areas contiguous to the coast, but outside the area of the territorial sea, to a depth of two hundred metres.

(2) The coastal State exercises over the continental shelf sovereign rights for the purpose of exploring and exploiting its natural resources.

(3) The rights of the coastal State over the continental shelf do not affect the legal status of the superjacent waters as high seas.

(4) The rights of the coastal State over the continental shelf do not affect the legal status of the airspace above the superjacent waters.

(5) Subject to its right to take reasonable measures for the exploration of the continental shelf and the exploitation of its natural resources, the coastal State may not prevent the establishment or maintenance of submarine cables.

(6) (*a*) The exploration of the continental shelf and the exploitation of its natural resources must not result in any unjustifiable interference with navigation, fishing or fish production.

(*b*) Subject to the provisions of paragraphs *a* and *e* . . . the coastal State is entitled to construct and maintain on the continental shelf installations necessary for the exploration and exploitation of its natural resources and to establish safety zones at a reasonable distance around such installations and to take in those zones measures necessary for their protection.

(*c*) Such installations, though under the jurisdiction of the coastal State, do not possess the status of islands. They have no territorial sea of their own and their presence does not affect the delimitation of the territorial sea of the coastal State.

(*d*) Due notice must be given of any such installations constructed, and due means of warning of the presence of such installations must be maintained.

(*e*) Neither the installations themselves nor the said safety zones around them may be established in narrow channels or on recognized sea lanes essential to international navigation.

(7) (*a*) Where the same continental shelf is contiguous to the territories of two or more States whose coasts are opposite to each other, the boundary of the continental shelf appertaining to such States is, in the absence of agreement between those States or unless another boundary line is justified by special circumstances, the median line every point of which is equidistant from the base lines from which the width of the territorial sea of each country is measured.

(*b*) Where the same continental shelf is contiguous to the territories of two adjacent States, the boundary of the continental shelf appertaining to such States is, in the absence of agreement between those States or unless another boundary line is justified by special circumstances, determined by application of the principle of equidistance from the base lines from which the width of the territorial sea of each of the two countries is measured.

(8) Any disputes which may arise between States concerning the interpretation or application of these articles should be submitted to arbitration at the request of any of the parties.

The construction of the boundaries between areas of national sovereignty over the sea bed is likely to be contentious. Applying Article 7, par. *a* to the North Sea, it would seem that the whole of its bed would become divided between Denmark, Germany, Holland, Belgium, France and the United Kingdom. However, the Norwegian Government presented a case which is accommodated by par. 66 of the Report. It remains open to Norway to protest that the existence of the Norwegian Channel, deeper than 200 m. and close to the Norwegian coast, is no hindrance to the claim of Norway to sovereignty over the shelf as far west as the median line which would be drawn if the Channel was not there.

Many conflicting views were expressed at the sittings of the Commission as to national rights to exploit fisheries and oil on or beneath the sea bed; but there has been little if any mention of rights of fundamental research by ships of one nation in areas of the continental shelf under the sovereign jurisdiction of another. Marine research workers would be wise to clarify for themselves what rights of scientific exploration they need, to decide whether these are in danger and, if they appear to be so, to represent through their national governments to the Commission or the General Assembly what amendments are needed to enable fundamental research at sea to proceed as freely in the future as in the past.

Under Article 3 it would seem that the work of the physical oceanographer or marine biologist on the waters over the shelf should nowhere be impeded. The coastal State can have no right to prevent the taking of water samples, the making of physical measurements or the working of pelagic nets in superjacent waters.

Scientific investigation of the surface of the sea bed with instruments, such as the trawl, would seem to rank with commercial demersal fishing. It is clearly understood that the rights of a coastal State do not cover so-called bottom fish and other fish which, although living in the superjacent water, occasionally have their habitat next to the bottom or are bred there.

The Commission held long discussions on the sedentary fisheries, such as that for the oyster. Disagreement between the jurists was radical and no firm agreement could be reached. The Commission has apparently concluded that the products of certain fisheries, particularly those for sedentary organisms permanently attached to the bed of the sea, should not be outside the regime of the coastal State.

If this opinion is accepted by the General Assembly, a coastal State would appear to acquire the right to prohibit any scientific investigation by a foreign ship of the zoology, geology or geophysics of the bed or 'subsoil' of the continental shelf under its jurisdiction. In the present temper of international relations—which oil in bulk appears not to lubricate—embargoes by coastal States on research appear a very real risk.

If the draft articles of the International Law Commission are accepted by the General Assembly of the United Nations and become the law of the high seas, it will be too late for institutions of marine research to complain that the law is not to their liking. Now is the time to establish that fundamental research by one nation is in the interests of all, and to ensure that the drafting is so amended as to permit fundamental research at sea to proceed without vexatious obstruction.

The Commission mentions "the possibility of creating an international agency charged with scientific research and guidance with the view to promoting, in the general interest, the most efficient use of submarine areas. It is possible that some such body may be set up within the framework of an existing international organization". The stress is not on unfettered, fundamental research, but on directed, 'useful', development work. Creation of yet another *ad hoc* body is to be deprecated. Already there exist the International Council for the Exploration of the (Western European) Sea and similar bodies in other areas; together with the International Unions of Geodesy and Geophysics and of Biological Sciences, the Association of Physical Oceanography and the Joint Commission on Oceanography, which are interlocked. There is every reason for using one or more of these bodies to guide the International Law Commission on scientific problems and to help to administer any machinery of registration and direction which may be forced upon the marine scientific community.

Initiative can be taken only by a representative national group of oceanographers and marine biologists, who would require first to decide whether the proposed developments of international law do indeed carry a threat to the freedom of marine research. If in Great Britain this should be agreed, the group would need to advise the Government on measures it could submit to the United Nations to ensure freedom of scientific research at sea; and it would at all stages need legal advice. Possibly the Royal Society would be the appropriate body to take effective initiative; the matter is clearly one of urgency, for it will take time for the various bodies interested to formulate their views and agree on a course of action.

THE PETROLEUM INDUSTRY

The Science of Petroleum

Vol. 5, Part 2: Synthetic Products of Petroleum. Edited by Dr. B. T. Brooks and Dr. A. E. Dunstan. Pp. x+330+31 plates. (London, New York and Toronto: Oxford University Press, 1953.) 100*s*. net.

IT seems appropriate that this addendum to "The Science of Petroleum" should have as its sole editors B. T. Brooks and A. E. Dunstan, to whom the inception of the whole work was mainly due. Both played a leading part in the development of present-day petroleum technology, and both were men of vision and the determination to turn their dreams into large-scale reality. Were they chemical engineers? Well, maybe. Brooks describes himself as such in his review of the production of other chemicals from petroleum hydrocarbons. But the volume is chiefly a justification by works of the organic chemist who has harnessed his fellow scientific workers and the engineer to his needs, yet has shown himself to be both an able scientist and an excellent technical director. Thought and faith are, indeed, mightier things than time can wrong, and even the modest editorial preface, and the foreword by a great leader of the oil industry, cannot obscure the achievements of the organic chemist in shaping the destinies of petroleum to their present impressive purposes.

Like its predecessors the supplement is a wise collection of contributions by leading specialists, sufficiently overlapped where necessary to cover the broad (and deep) sections into which the subject-matter falls. Like other treatises it was no doubt 'dated' as soon as written; but it is not thereby out of date. No work can be which is fundamentally treated, and this is certainly the case here. One may regret the absence of climax wrought or progress made since the initial publication; but the fact is that, with the basis well treated, additional material in most cases can be quickly absorbed from current literature. The editors and contributors are to be congratulated on providing unexceptionable material which will continue to be a reference however much new discovery is made. This is well seen, for example, in Section 1, which deals with synthetic products. The contributions on hydrocarbon polymerization lead from a general treatment through the special cases of the olefines and isobutylene polymers and co-polymers to butadiene, isoprene and styrene as raw materials for synthetic rubbers. All are of a high standard, and the article on chemicals for synthetic rubbers will certainly be used for reference for a long time.

The effect is not so well marked in the provision of only a single article devoted to surface-active agents, possibly because much had already been written on this subject prior to the use of petroleum as a raw material. Yet the domestic and industrial use of detergents, wetting agents, emulsifiers, and so on, derived from petroleum already comprises an industry, within the main industry, which is continuously expanding. It might therefore have been considered worthy of more extensive treatment than it has been accorded.

Section 2 is concerned wholly with refinery processes and starts off with a series of articles on fractionation. This is first-class material and is concerned with the fundamentals of design and methods of application. It gives a clear insight into the principles of refinery design. Something more might perhaps have been included on the details of heat transference as demanded by the less conventional conditions of heat exchange, and the same might be said of plate hydraulics and column design.

Attention will be chiefly focused on the parts dealing with the practical problems of hydrocarbon re-structure. That of chief interest is, of course, catalytic cracking, which started on a somewhat empirical basis and then rapidly moved into the field of calculation based on observational and theoretical considerations. Fixed bed, fluid technique and air-lift were all the results of the insatiable wartime demand for high-octane gasoline. All were worked out with finest regard to fundamentals as well as to the use of great changes in chemical engineering method. The five articles dealing with cracking will probably for all time best summarize the state of the art during the wartime decade. But it is significant that there they stop, there being scarcely a reference to work subsequent to 1947. It has already been pointed out that, in the publication of a compendium, such gaps are bound to exist, but it happens in this particular case that an important step has been taken during the interval: namely, the development of conjoint catalytic cracking, directive hydrogenation of olefines, and dehydrogenation of naphthenes, so as to produce the kind of gasoline wanted, and at the same time meet the ever-growing demand for the aromatics needed as intermediates by the synthetic fibre and plastics industries. This achievement has resulted largely from the discovery and use of special platinum catalysts, and it is a type of process which appears to be altering refinery practice profoundly and deserves close attention. With coal tar being rapidly ousted from its premier position as the source of the simpler aromatics, and the world demand for such aromatics being still unsatisfied, it is to be hoped that issue of the forthcoming Part 3 of Vol. 5 will be hastened and will meet the need for authoritative descriptive matter on the subject. It would be a good occasion also to show more clearly the dependence upon petroleum of the plastics and synthetic fibres industries which are taking such a big place in the modern world.

The book finishes with three articles on alkylation, the first being by its British co-originator and protagonist. These are permanent records but it is doubtful, with the disappearance of the internal-combustion engine from high-speed aircraft, whether alkylation will retain its past importance.

The volume is prepared with the same splendid care as those previously issued. It should be on the bookshelf of every student of petroleum from undergraduate and cadet to executive and director.

S. J. M. Auld

SEX HORMONES AND CANCER

Oestrogens and Neoplasia

By Harold Burrows and Eric S. Horning; with contributions by W. C. J. Ross and C. W. Shoppee. Pp. xv+189. (Oxford: Blackwell Scientific Publications, Ltd., 1952.) 30s. net.

In the words of a preface, written by Dr. Charles Huggins, this book is indeed "a chronicle of great events in cancer research", and to this it may be added that the chronicle is itself an excellent one. It is a comprehensive review of present-day evidence concerning the relations between the œstrogenic hormones and cancer, and for many years to come the long reference list will remain an invaluable tool in the hands of those entering this field of research.

The book begins with a brief but excellent description of the chemistry of the best-known œstrogenic substances, both natural and synthetic, together with much information regarding weak or non-œstrogenic substances. This leads to an account of the occurrence and metabolism of these compounds, an account which is expanded and enlarged from a physiological point of view in the second chapter. Thence the argument passes to a particularly interesting review of the influence of œstrogens on tissue growth, the tissues considered being not only those which are related to the sex function, but also those of the general body. The relation between excessive mitotic activity and cancer incidence is explored in a convincing manner, although, since the book went to press, there is some fresh evidence which suggests that this relationship may not be quite so straightforward as the present account might appear to indicate.

The remainder of the book is taken up with a detailed statement of evidence supporting the important conclusion that the œstrogenic hormones are to be regarded as essential agents in the causation of several kinds of cancer, although, of course, it is fully realized that they are unable to exert this effect unless their action is accompanied by that of certain other factors and conditions. Important in this connexion may be viruses, differences between species, hereditary differences within species, rate of food intake and so on. Considerable space is devoted to detailed accounts of tumours of the hypophysis, of the ovary, the uterus and the mammary gland, of the testis and the prostate, of the adrenal, and of several other tissues. Finally, there is also a chapter on the prospects of chemotherapy which, however, on present evidence are considered to be poor.

There are two features of the book which call for special praise. The first is the manner in which it is repeatedly stressed that basic research is of primary importance to an understanding of the problem of cancer and to the development of new techniques for treatment. A clear knowledge of the physiology and chemistry of normal growth is undoubtedly an essential prerequisite for an understanding of abnormal growth, and academic research to this end should be actively fostered. This obvious fact is commonly overlooked. The second unusual feature is the pleasure with which the book can be read. The arguments are always clearly and logically stated, and nowhere does the story degenerate into an undigested catalogue of conflicting facts, as is the case with so many books of its kind. From all points of view it can be highly recommended.

W. S. Bullough

PRODUCTION AND USES OF GLYCERINE

Glycerol

Edited by Carl S. Miner and N. N. Dalton. (American Chemical Society, Monograph Series No. 117.) Pp. xiv+460. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1953.) 96s. net.

The appearance of a most comprehensive treatise on glycerol, its sources, production, properties and uses, brings to mind the very large consumption of glycerine at the present time, and its wide range of uses. 'Glycerol'—the accepted chemical name given to the trihydric alcohol $C_3H_5(OH)_3$ by Chevreul (in virtue of its sweet taste)—and 'glycerine' are synonymous terms: it is useful, as the editors of the monograph agree, to retain both, employing 'glycerol' to designate it as a chemical entity and in considering its physical and chemical attributes, and leaving the long-used 'glycerine' in reference to its industrial forms and uses.

The annual world production of glycerine was estimated to be about 75,000 tons at the beginning of the century, and about 170,000 tons in 1939, while in 1950 it had reached more than 220,000 tons. For many years the United States has contributed about half the total production, while Great Britain has produced 15–20 per cent. The chief outlets for industrial glycerine may seem surprising: in the United States the largest use—nearly 30 per cent of the U.S. production—was in the manufacture of alkyd resins for paints and varnishes. Explosives, tobacco and cigarette manufacture, cosmetics with pharmaceutical preparations, and transparent cellulose tissue manufacture each absorbed 10–12 per cent, and the remaining 25 per cent was divided among a number of manufactures, including corks, printing inks, foods and beverages, textiles and adhesives. The proportions of glycerine used by different industries will be materially different in some instances in Great Britain, but the figures given by Miner and Dalton serve to indicate the general picture. The authors, indeed, ascribe to glycerine in the United States the position given by a Victorian statesman to sulphuric acid in England—an index of industrial production and the state of trade at large.

Until quite recently the only industrial source of glycerol was from fats and oils, as a secondary product in the manufacture of soap. Consequently, when sudden changes in demand arose—as for explosives in the First and Second World Wars, or when the new industry of alkyd resin manufacture developed on a large scale—glycerine supplies were temporarily inadequate and extreme fluctuations in price were liable to take place. During the First World War, processes were developed for producing glycerol in industrial quantities by modified yeast fermentation of sugar; but these did not compete with fat glycerine when the latter again became freely available in the inter-war years. Very recently, however, after many years research it has become possible to manufacture glycerol from propylene, a hydrocarbon now available in very large quantities from the pyrolysis of crude petroleum, and a full-scale plant for this purpose has been in operation in the United States since 1948. It is therefore unlikely that acute glycerine shortages will recur in the future. In normal circumstances it seems probable that the bulk of industrial glycerine will continue to be provided by the saponification of natural fats and fatty oils, while synthetic glycerine from propylene and, possibly, also glycerine from modified sucrose fermentation, will restrain any of the violent price fluctuations which formerly affected this market. T. M. Godfrey, who contributes the section of Miner and Dalton's monograph on methods of production, considers that, owing to refining difficulties, glycerine from sugar fermentation will not compete economically with that from the hydrocarbon synthesis; this is a matter of opinion, since there may be further scope for development in the recovery of glycerine from the fermentation liquors.

The widespread importance of industrial glycerine and the manner in which it has been possible to introduce supplies by methods alternative to its production from natural fats form a chapter in applied organic chemistry which will be of interest to the general reader. The purpose of the volume which has inspired the foregoing reflexions is, of course, more especially for those concerned in any way with glycerol, its production and its products. For these it will be found well presented and documented, and admirable in every way except its somewhat formidable price. The sections on the sources of glycerol technically available in natural fats and on its methods of production are specially valuable. The processes for hydrolysis of fats, concentration of glycerine to the 'crude glycerines' containing 80–90 per cent of glycerol, and distillation of the latter to yield 'distilled' or 'dynamite' glycerines are fully described with adequate diagrams and illustrations, and later sections (by J. B. Segur) deal with various agreed trade specifications for glycerine and with the many methods of analytical control required to ensure conformity with these. The last section of the monograph, devoted to the uses of glycerine, will prove of as much interest to the general reader as to the glycerine specialist.

The sections on the physical and chemical properties of glycerol and its derivatives are extremely detailed and contain a very large amount of valuable information. They occupy, however, 160 pages—more than one-third of the book; it might have been desirable, for the sake of producing a somewhat less expensive volume, to have considered whether these sections could not profitably have been materially condensed. This is the only criticism which it is desired to make about a monograph which is not only excellent but which was also needed.

T. P. HILDITCH

ASPECTS OF MODERN METALLURGY

(1) The Metallurgy of the Rarer Metals

Institution of Metallurgists. (Lectures delivered at the Institution's Refresher Course 1952.) Pp. 156. (London: Institution of Metallurgists, 1953.) 15s. 6d.

(2) The Physical Chemistry of Copper Smelting

By R. W. Ruddle. Pp. 156. (London: Institution of Mining and Metallurgy, 1953.) 20s. (10s. to I.M.M. members).

(3) Equipment for the Thermal Treatment of Non-Ferrous Metals and Alloys

A Symposium on Metallurgical Aspects of the subject held in London on the occasion of the Annual General Meeting of the Institute, 26 March 1952. (Institute of Metals: Monograph and Report Series No. 14.) Pp. 104. (London: Institute of Metals, 1953.) 15s.

(4) The Physical Chemistry of Melts

A Symposium on the Nature of Molten Slags and Salts held by the Nuffield Research Group in Extraction Metallurgy, London, 20th February 1952. Pp. 106. (London: Institution of Mining and Metallurgy. 1953.) 15s. (7s. 6d. to I.M.M. members.)

THESE four monographs, although containing little which is really new, are all able and valuable compilations.

(1) The first, dealing with the metallurgy of the rarer metals, is a collection of lectures delivered at the refresher course arranged by the Institution of Metallurgists in 1952. The metals considered by authors specially fitted to discuss them are uranium, beryllium, molybdenum, tungsten, titanium and zirconium, tantalum and niobium, metals of the platinum group and 'pure' chromium and manganese. Something is said in most cases about the preparation of the material, and its properties, uses and metallography are in each case considered.

(2) The consideration of the present state of the physical chemistry of copper smelting is most competently dealt with by Mr. R. W. Ruddle, of the British Non-Ferrous Metals Research Association, and represents apparently the preliminary study necessitated before further work on the extraction of copper is undertaken in that Association's laboratories. In the seven chapters, each of the important sections of the smelting process is considered in detail, and even those who are not directly concerned with the metallurgical aspects of the processes may find the treatment of the recovery of sulphur from the smoke of considerable interest. The book is an admirable summary of existing knowledge, well presented and discussed.

(3) In March 1952 the Institute of Metals held a symposium on the metallographic aspects of the equipment required for the thermal treatment of non-ferrous metals and alloys. The papers submitted are now published and should be of interest to all those who are concerned with the heat-treatment of metals, not only non-ferrous. Electric furnaces and

gas equipment are first considered, there is then a paper on batch and continuous annealing of copper and copper alloys, one on the bright annealing of nickel and its alloys, and finally three papers on the batch treatment, flash annealing and continuous heat-treatment of the alloys of aluminium. Twenty-nine plates give a very clear idea of the type of equipment which has been designed and used. The papers, however, are no mere description of plant and apparatus, this being linked to the underlying mechanical and metallographic changes which the treatments are desired to effect. The importance of the atmosphere in which the heating is carried out is emphasized in more than one of the communications, and in that on the bright annealing of nickel and its alloys is discussed in some detail. The utility of the papers is further enhanced by the discussion which resulted, and the whole forms a contribution to the subject of real importance.

(4) In some ways the fourth of these monographs is the most outstanding. In February 1952 a symposium was held on the nature of molten slags and salts by the Nuffield Research Group in Extraction Metallurgy, which is working at the Royal School of Mines, London, on the reactions of systems connected with the winning and refining of metals. Two papers deal with the constitution of liquid oxides and silicates; anomalies in the surface tension of silicates are then considered; and three other papers deal with the correlation between activity and composition in mixtures of fused salts, heats of mixing in the liquid ferrous oxide–silica system and the thermodynamic aspects of molten slags. Each of these presents a clear picture of the present state of knowledge, and it will perhaps surprise many readers to find how wide this already is. To those who are in any way concerned with the physical chemistry of molten salgs and salts, this little book may be most strongly recommended.

F. C. Thompson

INORGANIC CHEMISTRY FOR THE GENERAL STUDENT

General and Inorganic Chemistry
By Dr. P. J. Durrant. Second edition. Pp. x+671. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1952.) 21*s*.

Reference Book of Inorganic Chemistry
By Prof. Wendell M. Latimer and Prof. Joel H. Hildebrand. Third edition. Pp. xiii+625. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1952.) 37*s*. 6*d*. net.

AT a time when the supply of scientific workers and technologists is of national importance in Britain, it is a matter of some concern to consider their early training, so often provided in the sixth forms of schools. The teacher at this stage has the heavy responsibility of laying firmly and wisely the foundations of the sciences, while at the same time encouraging interest and enthusiasm in a particular science, frequently chemistry. To achieve this in a rapidly advancing subject such as chemistry, the methods of presentation must be constantly under review. The teacher has available to aid him in this several excellent text-books, constantly under revision, which are known affectionately by the names of their authors. "Durrant" is one of these, now appearing in a second edition.

The new edition has several modifications and additions, including a completely revised chapter on valency, atomic structure and the periodic table, which now introduces the numerical concept of electro-negativity as well as the qualitative treatment afforded by Fajan's rules. The importance of ions in the understanding of a great deal of 'elementary' chemistry is emphasized by revision of the chapters dealing with electrolytes, electrode potentials and electrolysis. The treatment given to the electrochemical series and to electrode potentials will be of particular value to teachers. New chapters have been added to cover colloids and nuclear chemistry (including nuclear and thermo-nuclear energy). A treatment of colloids forms an essential part of any elementary course intended to introduce the student to the chemistry of the world about him, and its inclusion is thus to be especially welcomed. In some measure the same may be said of 'nuclear chemistry' in this atomic age.

A modified form of the periodic table due to Prof. T. S. Wheeler is used in which the *A* and *B* sub-groups of the short table are re-styled *N* and *T* (normal and transition) sub-groups. Some will find its use advantageous; but it seems to me that the subject is at such a stage of development that the few advantages of the short form should be shelved in favour of the exclusive use of the more open and obvious long form.

The book is well prepared, and there are only a few trifling mistakes. On a point of nomenclature it is unfortunate that the author should have deviated from what has become established practice in referring to the 'actinides' as 'uranides'. A particularly attractive feature of the book is the large number of questions (401) covering a very wide range of sources. This text-book will continue to play an important part in the teaching of 'elementary' chemistry, and the revised second edition is to be highly recommended both for school and university work.

The third edition of the "Reference Book of Inorganic Chemistry", by Profs. W. M. Latimer and J. H. Hildebrand, is not intended primarily as a text-book, but can be adapted by the teachers to suit their own particular requirements and thereby provide the elementary student with a book containing a wealth of facts arranged and rationalized mainly in terms of the atomic structures and fundamental properties of the elements. As a reference book its value may appear doubtful because of its size, which is very small compared with the better-known reference books of inorganic chemistry. However, there has been a most skilful selection of facts, and there is a surprising amount of material contained within the 511 pages of text and the 86 pages of glossary and appendix. Much of the information in the text is summarized in tables setting out data for particular groups of elements or compounds. The appendix includes a large collection of useful data (notably a table of the m.p., b.p., density, etc., for around 1,300 inorganic substances). This third edition is considerably revised from the second edition (1940), and includes a new chapter on nuclear reactions and the actinide elements. It is unlikely to find any great use in Britain as a text-book, since more suitable works are available; but as a handy source of simple facts or data of inorganic chemistry it will be a decidedly useful volume to have on the bookshelf.

D. S. Payne

Trusts and Foundations

A Select Guide to Organizations and Grant-making Bodies Operating in Great Britain and the Commonwealth. Compiled by Guy W. Keeling. Edited by Thomas Landau. Pp. xi+194. (Cambridge: Bowes and Bowes Publishers, Ltd., 1953.) 42s. net.

IN the foreword to this book, Lord Nathan, formerly chairman of the Committee on the Law and Practice relating to Charitable Trusts, points out that, though the Charitable Trusts Act has been in operation for a hundred years, this year being in fact its centenary, yet no one, not even the Charity Commissioners, can say with precision how many charitable trusts exist in England and Wales. The figure given to Lord Nathan's Committee is eleven thousand; but it is generally agreed that the actual number is greater. The present work gives a selection of a thousand bodies within Great Britain and the British Commonwealth that afford grant-aid, with information supplied by them regarding their resources and activities. Each body is given a separate paragraph, and they are listed in alphabetical order, the whole taking up more than three-quarters of the book. The rest of the space consists of a classified index arranged according to the Dewey Decimal Classification, an alphabetical subject index, an appendix of grants made by government departments to voluntary agencies, and a bibliography, this last-named being divided into a list of local directories arranged by county and town, and a list of publications arranged by subject. The value of this guide as a whole lies principally in the amount of time that it will save, both for applicants and for the body that is approached. In spite of the increased amount of money that is nowadays forthcoming from the State, there is still a need for these private trusts, for, as many a research worker will testify, they perform a valuable service in many fields of scholarship and welfare. So long as they continue, it is essential that those seeking grants should know which is the appropriate body to turn to, and this book is a modest start in regard to providing such information.

Common Ocean Fishes of the Californian Coast

Fish Bulletin No. 91 of the Marine Fisheries Branch, Department of Fish and Game, State of California. By Phil M. Roedel. Pp. 183. (San Francisco: Dept. of Fish and Game, 1953.) n.p.

THIS bulletin is designed as a guide to those marine fishes of California that are likely to be caught by commercial and sporting fishermen. Deep-sea fishes and the small forms from inshore waters that rarely, if ever, enter the fishermen's catches are not included. This guiding precept of likelihood of capture by fishermen has resulted in the inclusion of some species that are actually quite rare in California and the exclusion of some ordinarily common ones. The bulletin is meant for everyone interested in fishes regardless of his technical background, and scientific terminology has been kept to a minimum. Such terms as do appear are defined in a short glossary.

A brief description of each species is accompanied (with only a few exceptions) by a photographic illustration of an adult fish. Most of the illustrations are of a reasonably high standard; but a few—of admittedly difficult subjects—are disappointingly poor. Notes on fishing seasons and fishing gear are also provided. In addition to its scientific name, each fish is given what is described as an "official" common name. These "official" common names have been assigned by the Department of Fish and Game of the State of California in order to obtain reasonable consistency in terminology—an essential in the collection of accurate statistical and other information.

An identification key is included for the more common species. Such an incomplete key is often more of a hindrance than a help to the unwary novice who tries to identify a specimen that is not in the key. How is he to know whether his failure to name his fish is due to its omission from the key or to his having 'taken a wrong turning' somewhere? To be of real use a key must contain all the species likely to turn up. This, however, is a small point—and keys are notoriously difficult to compile, anyway.

A University Text-Book of Physics

Vol. 3: Heat. Being the eleventh edition and a largely rewritten version of Poynting and Thomson's "Text-Book of Physics", Vol. 3. Pp. x+439. (London: Charles Griffin and Co., Ltd., 1952.) 36s. net.

THE publication of this book raises an interesting question. Can a text-book which was brilliantly successful thirty years ago be successfully revised for the present generation of students? The reviewer regretfully feels that the answer must be 'no'. Mr. J. H. Awbery has made a valiant attempt to bring the material up to date; but there is no doubt that, during the past thirty years, the scope of physics teaching in the universities has vastly changed (for better or worse), and much of what appears in this book is now of pre-university standard. In the final chapters, on thermodynamics, where the revision has been greatest, modern standards are adhered to; but then there are other books (including Mr. Awbery's own) which deal successfully with this part of the subject.

In the reviewer's opinion, therefore, it is wiser to leave the classics as they were written for their own times, and to allow the present generation of authors to produce their own text-books in their own way.

H. L.

Weather Inference for Beginners

Made clear in a Series of Actual Examples. By D. J. Holland. Pp. xiv+196. (Cambridge: At the University Press, 1953.) 30s. net.

IN this book the author adopts the novel idea of taking the weather-changes over a sequence of days (in the autumn and winter of 1936) as he observed them in London with the simple apparatus available to a boy, and using them as the text for a series of simple explanations of the physical processes in the atmosphere which caused them. Both physics and meteorology are fairly advanced but should be quite intelligible to most readers, except perhaps where vectors are introduced, and this part of the book should be very useful to science teachers in schools where weather records are kept. Later, the observations are related to simplified synoptic charts of western Europe for the same period, and the reader is introduced to anticyclones, depressions and fronts. The remarks on frontal analysis should be of value to young entrants to the meteorological services learning the elements of weather forecasting, as also should be the concluding chapter on upper-air analysis, use of analogues and other aspects of practical forecasting. The chief difficulty, for the readers for whom the book is intended, is likely to be the high price, due no doubt to the lavish production.

THE CONTINENTAL SHELF

ONE morning of the British Association meeting at Liverpool was devoted to a joint discussion by Sections C (Geology), D (Zoology) and E (Geography) on problems of the continental shelf. First, Dr. L. H. N. Cooper, of the Marine Biological Laboratory, Plymouth, developed a hypothesis to explain the fluctuations in biological productivity of the English Channel in terms of climatic conditions in the Arctic. During the 1920's the Channel contained about 0·7 µgm.-atom/litre phosphate as measured at the winter maximum, and there occurred an abundant macroplankton characterized by several biological indicators, including *Sagitta elegans*. About 1930 the winter maximum of phosphate fell and settled down at about 0·45 µgm.-atom/litre. This was accompanied by a marked decrease in abundance of macroplankton and a change in the indicator species, *S. setosa* replacing *S. elegans*. Herrings also became less abundant, and after 1934 the Plymouth commercial herring fishery was completely extinguished. Evidence for a complementary earlier enrichment is incomplete; but there is some evidence for it shortly before the nutrient studies started in 1923. An explanation is likely to be in terms of an event that occurs only a few times in a century.

During the years 1947–50 the search for an explanation was extended to the Celtic Sea, south and west of the Scillies. Waters were found of *elegans* type and richer in phosphate than those near Plymouth; but none was as rich as that in the Channel during the 1920's. Within this area there is not a single clue which would suggest to-day a physical regime fundamentally different from that of thirty years ago. Since, whatever the ultimate cause may be, it is not local, the search has to be extended to the Atlantic Ocean.

Upwelling due to off-shore or off-slope winds is one possibility. However, during six weeks covering the notorious February of 1947, easterly winds were strong enough and lasted long enough to bring about upwelling of deeper water, but no enrichment ensued. Work later on R.R.S. *Discovery II* showed that to-day in the neighbouring Atlantic adequate nutrient resources are not within reach of any physical forces which could bring them to the surface. To make this possible, the nutrient table containing 0·8 µgm.-atom/litre would need to be raised by about 400 m. The conclusion seems inescapable that thirty years ago this nutrient table must indeed have lain 400 m. higher in the water than it does to-day and that it had been raised by upward displacement by an equal volume of water intruded at a greater depth, perhaps at the very bottom of the Atlantic. Abyssal water is always cold, having sunk from the surface in winter in high latitudes. It was concluded that much polar water must have sunk in the years before 1921 and that relatively little is sinking now.

Two events are necessary for the production of deep water in high latitudes: the presence of water of sufficiently high salinity; and air temperatures low enough to cool this saline water sufficiently for it to become the heaviest water in the North Atlantic. A principal northern area where this may occur is around southern Greenland. A series of cold winters there during the first twenty years of this century culminated in three very harsh winters in 1918, 1920 and 1921, during which time much deep Atlantic water must have been formed, leading to upward displacement of the overlying water. Nothing comparable has been experienced since, so that upward displacement and resulting nutrient enrichment of surface waters should have become much reduced.

It is suspected that this conclusion has emerged first from work on the English Channel because this has mostly a rock or sand bottom. Due to its strong tidal currents, there is little local deposition of organic mud or ooze. In regions of weaker tides, during years of rich production a capital reserve of organic mud is thought to be laid down and then by slow decomposition to yield dividends of nutrients and growth-promoting substances for many years afterwards. Thus, in such places, the failure to recruit fresh supplies of nutrients derived from oceanic upward displacement may be masked.

In the discussion, Dr. R. E. Craig, of the Scottish Home Department Marine Laboratory, Aberdeen, strongly supported the policy of looking at major climatic changes as first causes of observed hydrographical and plankton changes, but felt that the hypothesis merely presents a mechanism for increasing the thermal circulation and cannot necessarily be expected to raise the level of any of the horizontal boundaries in the sea. He also felt that 1921 was in every way an exceptional year able to produce the observed changes by the means which he outlined.

The Bear Island Shelf was the subject of a paper by Mr. Michael Graham and Mr. A. J. Lee, of the Fisheries Laboratory, Lowestoft. It lies between Norway and Spitsbergen, receiving from the north-eastwards a cold current against which two branches of warm, more saline Atlantic water impinge: the West Spitsbergen and the North Cape currents. As it is the site of the greatest single British fishery, conditions over it have been extensively studied by the fisheries research vessel *Ernest Holt*. The success of the fishery is found much to depend on where and to what extent Atlantic water of temperature 2–4° C. touches the sea bed. In March 1949 west of Bear Island such water extended from a depth on the shelf of about 150 m. to beyond the trawlable limit of 500 m. There was no ice about. On the same date in 1950 there was ice extending 30 miles west of the island, and no water warmer than 2° C. was found above 220 m.—that is, 70 m. deeper and about nine miles nearer the edge of the shelf. The breadth of the trawlable zone had become less than ten miles.

In 1949 much saline Atlantic water was present, having been blown there by preceding south-easterly winds. The presence of such saline water favours the formation of homogeneous water and hampers the development of surface ice. The distribution of density showed that the shelf waters west of Bear Island had become heavy enough to cascade over the edge and down the continental slope. In Mr. Lee's opinion, cascading down the slope of the shelf is an essential part of the mechanism thought to govern this spring fishery. The conditions of the fishery during the rest of the year were also described.

The title of the last paper, "Territorial Problems associated with the Continental Shelf", whetted curiosity since few of the audience realized that there were any. Dr. A. E. Moodie, a geographer of Birkbeck College, London, presented to zoologists and geologists an account of the evolution of international law relating to the sovereignty of coastal States over the continental shelf. Though the implications were clear enough, the story seemed as unreal as that of a comic opera and could have no place in a discussion on natural science. [See also p. 1063 of this issue of *Nature*.]

Since 1939, and especially since 1945, there has been a spate of claims to exercise sovereignty over the shelf, especially by American Republics. The United Kingdom has been party with Venezuela to a division of the Gulf of Paria. Motives have been twofold: the search for oil and the attainment of security. Many unilateral claims have been extravagant, and the legal position was becoming chaotic. In 1948, therefore, the General Assembly of the United Nations recommended to the International Law Commission that it should give priority to discussions on the regime of the high seas. After five years of argument and counter-argument, the Commission has agreed to recognize in principle qualified sovereign rights of a coastal State over the adjacent part of the shelf. It does not follow that the General Assembly will accept them.

The latest information available to Dr. Moodie was United Nations Press Release *L*/47, dated July 17, 1953, while the jurists were still sitting. The draft articles in full with an extended commentary were published on August 17 as United Nations General Assembly *A/CN*.4/76, pp. 35–56. This document shows that the Commission recommends that all contiguous waters shall be divided into two zones: the territorial sea, broadly equivalent to the present concept of territorial waters extending from the coast for three or some other number of miles to seaward; and the continental shelf, extending from the limit of the territorial sea to a depth of 200 m. The major difference in legal status will be that within the territorial sea the coastal State exercises, as previously, complete sovereignty over sea-floor, subsoil and superjacent waters, whereas over the continental shelf the superjacent waters and air-space will not be subject to the sovereignty of the coastal State. Over the whole of the continental shelf the coastal State will exercise sovereignty over the exploration and exploitation of the sea-bed and subsoil, just as it does over its land territory. The extension of the seaward boundaries of a coastal State to the 200-m. contour means a very great extension of the State's authority and could in some circumstances become a grave hindrance not only to trade and fishing but also to scientific research. Juridical problems, affecting the freedom of marine research, may arise when two or more States lie adjacent to the same continental shelf.

XIX INTERNATIONAL PHYSIOLOGICAL CONGRESS, MONTREAL

THE XIX International Physiological Congress was opened in the Sir Arthur Currie gymnasium of McGill University, Montreal, on Monday, August 31, 1953, at 5 p.m., by the president, Prof. C. H. Best, of the University of Toronto. The platform party made an imposing entry to the large gymnasium filled with more than two thousand members of the Congress, who stood in respect as their senior colleagues, together with the dignitaries of Montreal and of Quebec Province, passed along the centre aisle. This impressive stage-management was characteristic of the superb efficiency with which the local organizing committee, ably led—and perhaps driven—by Prof. F. C. MacIntosh, of McGill University, had organized the whole of this vast Congress.

Following the official opening of the Congress, the remainder of this plenary session consisted of speeches of welcome from Dr. J. B. Collip, president of the Canadian Physiological Society, which was the host organization to the Congress; from Dr. F. C. James, principal of McGill University, on behalf both of McGill University and of the University of Montreal; from Mayor Camillien Houde, on behalf of the city of Montreal; and from Dr. G. D. W. Cameron, deputy minister of health, on behalf of the Government of Quebec. The president of the Congress conveyed the thanks of all members to the many host organizations, in a large variety of languages, including Iroquois; in fact, the linguistic attainments of the platform party were astonishing, from Dr. Collip's speech in French, onwards; but the thunder of the whole session was stolen by Mayor Houde, whose memorable address made even vital statistics vital. Shortly before the close of the meeting, Dr. E. D. Adrian, of the University of Cambridge, outlined the plan of the Permanent Committee, of which he is president, for the establishment of an International Union of Physiological Sciences, and promised members that the Permanent Committee at least intended to work during the Congress—and hoped to present the final recommendations at the closing plenary session. The entire concourse then made its way very slowly up a steep hill to Forbes Field, where, in the open air, all were entertained at the hands of the Provincial Government of Quebec. This reception was memorable, not only for being held in such pleasant surroundings, not only for the unrivalled opportunities for meeting, for the first time, many of one's fellow members, not only for the generous spirit of the Government of Quebec, but also for a buffet which broke all records in running out of soft drinks and soda-water only. In this way then did August fade away, and on the first of September members were faced with a staggering programme of scientific sessions, and the technical work of the Congress began.

It is said in North America that only the English can talk uninterruptedly for longer than thirty seconds about the weather; but all racial records were broken in Montreal, where, despite the unparalleled opportunities for 'shop', the climate must surely have taken pride of place as a subject for discussion. The Congress basked or baked in temperatures that seldom—or was it ever?—fell out of the 90's, and members were little comforted by the repeated assurances of the 'locals' that this was most unusual for the time of the year. Recollection of sessions in hot and crowded lecture halls will remain long after memory of the scientific proceedings has faded; but more comfortable recollections of the ample standing, seating and lying accommodation will also linger.

There were some 2,750 registrations in all, more than two thousand being full members of the Congress. There were eight symposia, eighteen films, fifty-eight demonstrations and 792 communications. This programme was completed in a total of seven half-day sessions, and there were never fewer than fourteen nor more than seventeen concurrent activities. This report must therefore be selective and must inevitably show bias in referring mainly to work in one major field of interest; it is proposed to mention only a few points of interest from the 792 communications and to describe briefly the subject-matter of the symposia.

The organization of an international meeting of this magnitude throws an indescribable burden of work on the scientific personnel of the host country and, even more, of the host city. One is inevitably left reflecting whether it is worth the labour, or whether some alternative plan for the Congress would not ease the load. The idea of more frequent, small-scale international symposia is attractive and is becoming more and more a feature of scientific discussion nowadays; but they can only serve as an adjuvant to the full Congress. Let us therefore accept the restrictions and the inevitable frustrations of the large-scale meeting, and agree that only at such a meeting can one meet and talk with those in wholly different fields of work; more can be learned in private conversations than in formal lecture halls.

First, in the neurophysiological field, R. Stampfli (Berne) has introduced a 'simple' method for measuring membrane potentials and, as a result, we may find that, in the future, even the old-school pharmacologists will indulge in talk of "resting potentials".

V. B. Brooks (Montreal) provided a beautifully logical exposition of the action of *Botulinus* toxin in blocking conduction in the fine non-myelinated terminal filaments of motor nerves. This has long been assumed but never before so adequately proved.

A. von Muralt (Berne) has further enlarged the neurophysiological vocabulary with 'stroboscopic photochemistry' and, with elegant technique, has shown that light at various optimal wave-lengths can greatly influence the threshold of a single nerve fibre. The changes depend on the time relationship between the light flash and the electrically excited action-potential; and on whether the flash is directed on a node of Ranvier or on an internode. Light of wave-length 280 mμ can inactivate enzymes which may play a part in the chemical reactions providing the free energy for the maintenance of excitability.

It was a pity that A. V. Kibjakow (Kazanj, U.S.S.R.) was not present to read his paper (read by title only), for the abstract is most stimulating. In particular, it is interesting to note that he finds that chronic pancreatectomy reduces the output of acetylcholine from cholinergic nerve-endings. He has resisted the obvious temptation to speculate as to the reason for this observation, except to attribute it to a disturbance of phospholipid metabolism. He proceeds, however, to discuss in considerable detail the function of the animal thus partially deprived of one of the mediators of nervous transmission, and further open discussion of this question might have been most enlightening.

H. Konzett and E. Rothlin (Basle) settled one outstanding query in connexion with the effects of denervating an organ when they showed that neither the increased sensitivity of ganglion cells to acetylcholine nor the depletion of cholinesterase in the ganglion—both of which are found after denervation—is obtained after long-term block of ganglion transmission with a ganglion-blocking drug. Thus, the 'trophic' effect exerted by the intact pre-ganglionic fibres cannot be dependent upon constant reaction of the cells to the normal transmitter.

E. M. Vaughan Williams and S. W. Kuffler (Oxford and Baltimore) have most ingeniously devised a means of recording both 'fast' or 'twitch' and 'slow' striated muscle fibres in the frog rectus muscle, and have shown that the muscle responds to acetylcholine by a contracture due to activation of the 'slow' muscle fibres only, the 'twitch' fibres relaxing rapidly in the acetylcholine solutions. It appears that no muscle fibres have a double innervation, the 'slow' fibres being innervated by small-diameter nerves only. This work has gone far towards resolving the nature of the system used, in ignorance, for so long as a routine pharmacological test for acetylcholine activity.

R. H. Beutner (Little Rock, U.S.A.) and T. C. Barnes (Philadelphia) discussed artificial cell membranes; both have long used a lipid-saline interface as a physical model of a cell membrane, and the 'electrogenic' effects of acetylcholine on such a system are impressive. Recent advances in our knowledge of the nature of the action potential has, however, convinced most of us that these models can only be regarded as a vast over-simplification of a most complex situation.

F. C. MacIntosh and P. E. Oborin (Montreal) presented what must be the first convincing evidence that acetylcholine is involved in cerebral cortical activity. The acetylcholine released is collected in a small 'Lucite' cup containing eserinized saline placed on the surface of the cortex. Fluid transudes from the cortex into the cup at a rate of about 0·02 ml./cm.^{2}/min., and the concentration of acetylcholine in this fluid during light anæsthesia may be as high as 3×10^{-7} gm./ml. The amount of acetylcholine released is proportional to the electrical activity of the cortex and may be modified by the depth of anæsthesia. The acetylcholine is not derived from parasympathetic vasodilator fibres, and the fluctuation in the amount of acetylcholine released is not accounted for by changes in cerebral blood flow.

Ruth S. Geiger and A. Behar (Jerusalem) described a technique for the growth of neurones in tissue culture. They used grey matter from adult rabbit brain and observed mitosis of neurones in the cultures. Cortisone was more successful than embryo brain extract as an adjuvant to the basic Tyrode's solution and serum mixture; it increased the survival time of individual neurones, prevented the growth of most cells other than neurones, and increased the frequency of mitosis in neurones ten to twenty times.

A. O. Zupancic (Ljubljana, Yugoslavia), who was unfortunately not present, made the suggestion in his abstract that the receptors on cell membranes, to which specific transmitters attach themselves, are one and the same molecules as the enzymes responsible for their destruction. This interesting speculation has many attractions, but seemed somewhat at variance with the findings obtained by specific staining for enzymes, which indicate that although the cholinesterase at the end-plates of striated muscle appears to be located at the post-synaptic membrane, the cholinesterase at the ganglion synapses seems to be mainly in the pre-synaptic terminals.

Turning to fields other than neurophysiological, it was noted, in passing, that C. P. Lyman and D. W. Fawcett (Boston) had shown that exposure to cold of a hibernating mammal (the golden hamster) causes a desaturation of the white fat, whatever the degree of saturation of the dietary fat. This explains how the hibernating animal can maintain its fat stocks in the fluid state, in spite of the fact that fat from animals maintained at 22° C. is semi-solid at 5° C.

H. E. Essex, H. L. Smith and E. J. Baldes (Rochester) did great service for the average medical student—shades of the ward-round!—in producing a first-rate film (with sound recordings), illustrating beyond reasonable doubt that the first heart sound can be attributed to closure of the mitral and tricuspid valves, and the second to the closure of the aortic valves.

Both D. R. Drury and A. N. Wick (Los Angeles) and R. Levine and M. S. Goldstein (Chicago) read papers supporting the view that the action of insulin in facilitating the metabolism of glucose is due, not so much to a direct effect of insulin upon the responsible enzyme systems but to its effect in promoting the transfer of sugar across the cell membranes, and hence, indirectly, to a more rapid intracellular metabolism.

A whole morning was devoted to papers on glucagon, the hyperglycæmic factor of the pancreas. There has long been scepticism about this 'hormone', but it now appears that it is a real entity. A. Staub, L. Sinn and O. K. Behrens (Indianapolis) described its isolation in crystalline form, and C. de Duve and C. A. Vuylsteke (Louvain) also had achieved a substantial degree of purification. De Duve and Vuylsteke have also improved the assay method using isolated rabbit-liver slices, originally proposed by Sutherland and de Duve. A group meeting on glucagon was also held during the Congress, and it was suggested that the question of standardizing glucagon should be referred to the World Health Organization.

Two group meetings on secretin, organized by M. H. F. Friedman (Philadelphia), were held, and a series of recommendations about the establishment of an international standard for secretin was prepared for submission to the World Health Organization.

D. J. Smith (Burlington, U.S.A.) showed that thyroxine can exert an immediate effect on isolated arteries, increasing their sensitivity to adrenaline by some 250 per cent. The sensitivity of vasa vasorum was even more greatly enhanced by thyroxine. Smith suggested that these effects were due to inhibition of amine oxidase by thyroxine.

R. Carrasco-Formiguera and N. Pi-Sunyer (Caracas, Venezuela) have provided further evidence that the shift in the Arneth count observed in clinical hyperthyroidism, is attributable only to a hypersecretion of thyrotrophic hormone and, like exophthalmos, is not produced directly by thyroxine.

H. C. Meng and Charlotte Hollett (Nashville, U.S.A.) have succeeded in partially separating the anti-coagulant and the lipæmia-clearing activities of heparin by various chemical procedures which reduce the anti-coagulant activity only. The relationship of these findings to the chemical structure of heparin is still unexplained.

Many members of the Congress were interested (and amused) to note that J. Ek and B. Josephson (Stockholm) have found that beer is just as good a diuretic as theophylline—and that this is quite independent of its volume and action in producing a simple water diuresis. The National Health Service in Britain may find even more 'proprietaries' being prescribed as a result.

The symposium on the morning of September 1 on the metabolic influence of insulin was held under the chairmanship of Dr. B. A. Houssay. The principal speakers were F. D. W. Lukens (Philadelphia) on the influence of insulin on protein metabolism; De Witt Stetten (New York) on the inter-relationship of carbohydrate and fat metabolism; F. G. Young (Cambridge) on the inter-relationship of pituitary and pancreas; and W. C. Stadie (Philadelphia) on the action of insulin *in vitro*. These papers were largely reviews of present-day knowledge of these facets of insulin metabolism; but Lukens had fresh evidence to show that carbohydrate in the diet led to nitrogen retention in normal but not in hypophysectomized cats, and Young, that in adrenalectomized animals purified growth hormone exerts a diabetogenic action. Stadie's stimulating paper described experiments *in vitro* on the binding of insulin by various tissues. Of all tissues examined, only brain failed to bind insulin, and by using insulin labelled with radioactive isotopes of sulphur and iodine, it had been possible to determine insulin in amounts of the order of 0·01 μgm. Measurements have been made in this way of the effect of insulin upon the synthesis of glycogen in strictly quantitative terms of tissue, substrate and hormone.

In the afternoon, a symposium was held under the chairmanship of Dr. B. Folkow on the hæmodynamics of small vessels. The principal speakers were A. C. Burton (London, Ontario), B. W. Zweifach and D. B. Metz (New York), J. R. Pappenheimer (Boston) and H. Barcroft (London, England). Burton spoke of the structure and function of the elements in the wall of blood vessels; Zweifach and Metz on the functional behaviour of the terminal vascular bed; Pappenheimer on molecular exchange processes in the capillary circulation; and Barcroft on the control of muscle blood flow. Barcroft's contribution, given with typical modesty, was a masterly exposition of what is, and is not, known in this field. The dilatation of the vessels supplying active muscle fibre appears to be entirely accounted for by some change in muscle initiated by the contractile process.

The first of the symposia on September 2 was held under the presidency of Dr. C. F. Schmidt, on reflexes from the cardiac and pulmonary areas. C. Heymans (Ghent) led off with a paper on sino-aortic receptors, in which he reviewed the work on the carotid body, including his own classical and elegant experiments which began in 1924 and are still continuing. O. Krayer (Boston) reviewed the history of the Bezold–Jarisch effect, and was followed by G. S. Dawes (Oxford) on reflexes from the heart and lungs. Dawes attempted a badly needed survey of the many reflexes which have been reported in the literature and appealed for clarity in describing them, and for the necessity for the adoption of rigid criteria for their classification. He ended with the speculation as to whether many of these reflexes, excited as they are only by drugs, have any useful purpose in normal life. Y. Zottermann (Stockholm) read a paper on electrophysiological investigations of afferent fibres from the carotid sinus region, and made the interesting suggestion that acetylcholine acts as a transmitter of impulses in the carotid body, the glomus cells and the nervous end-plates corresponding to functional synapses. This is a point of lively controversy which has excited discussion for many months. Finally, D. Whitteridge (Edinburgh) discussed the electrophysiology of afferent cardiac and pulmonary fibres, and described new work in his laboratory by Paintal, who has developed an interesting method for the isolation of single small fibres based on conduction-rates. This was, in all, an excellent symposium of papers of a uniformly high standard of excellence.

On the afternoon of September 2, under the presidency of Dr. F. Bremer, a symposium was held on postural mechanisms. This was opened by S. W. Kuffler (Baltimore) on segmental mechanisms, in which he began by assessing our knowledge of posture as rudimentary, and ended on a Sherringtonian note with the conclusion that postural tone is part and parcel of ordinary motility. He was followed by B. R. Kaada (Oslo) on suprasegmental mechanisms. This paper also showed a well-marked integrative action and introduced the role of the labyrinth, the cerebellum and the reticulum. H. W. Magoun (Los Angeles) went on to describe in more detail reticular and striate mechanisms of postural control, and G. Moruzzi (Pisa) rounded off another successful symposium with a paper on cerebellar and cerebral mechanisms. His review was highly technical and somewhat difficult to follow, as indicated by the fact that he cited no less than ninety-five references.

On the morning of September 3, the symposium was on the more general subject of the physiological theories of learning, the chairman being Dr. K. S. Lashley. J. Z. Young (London, England) led off on the learning system of octopus. This work, though lacking somewhat in pristine freshness, is none the less of great importance. R. W. Sperry (Bethesda) continued on regeneration studies and learning, and presented some most interesting data, together with a somewhat rarefied discussion of their physiological, psychological and even philosophical bases. He was followed by K. M. Bykov (Leningrad) on the physiology and pathology of the cerebral cortex. Here again, the rarefied atmosphere of dialectical materialism, coupled with the more mundane difficulties of language, made real insight into his thesis somewhat tricky. The symposium ended with a contribution from A. K. MacIntyre (Dunedin) on synaptic function and learning, which came as a welcome return to the bedrock of electrophysiology.

On the morning of September 4, the symposium was on the mechanism of formation of the thyroid hormone, the chairman being Dr. J. Roche. The principal speakers were E. B. Astwood (Boston) on iodine-collecting mechanisms; R. P. J. Michel (Paris) on the localization and the mechanism of iodination concomitant with the formation of thyroglobulin; E. D. De Robertis (Montévideo) on the physiological hydrolysis of thyroglobulin in the thyroid gland; J. Gross and Rosalind Pitt-Rivers (New York and London, England) on the passage of tri-iodothyrin and thyroxin into the circulation. Finally, during the afternoon, a symposium was held on the physiology of cold, in which the principal speakers were E. F. DuBois (New York) on the physiology of homœothermic animals exposed to cold; L. P. Dugal (Quebec) on endocrine glands and cold; C. Kayser (Strasbourg) on hibernation in mammals; O. G. Edholm (London, England) on the effect of cold on the circulation of man; and Norma C. C. Kent and N. H. Mackworth (Cambridge) on the effects of cold on human efficiency.

To add to the already bewildering choice of activities that confronted members of the Congress, there were a large number of open, semi-private or private meetings of specialist groups, organized by various private individuals, and held, in the main, concurrently with the official sessions. The largest of these and the only one which it is possible to mention ran as an open meeting for the whole of one day. It was organized by Prof. C. von Euler (Stockholm) on the subject "Biologically Active Polypeptides". It was at this meeting that Van Dyke (New York) announced what was perhaps the most notable scientific advance reported at the Congress, namely, that Du Vigneaud (New York) had succeeded in synthesizing the oxytocic hormone of the posterior pituitary. This is in every way a major advancement, and may well pave the way for further syntheses of biologically active polypeptides.

On September 4, at 5 p.m., a somewhat bedraggled Congress assembled in the Salle de Promotion at the University of Montreal for the closing plenary session. The platform party on this occasion included Cardinal Leger, chancellor of the University of Montreal. Dr. C. H. Best, president of the Congress, offered the thanks of the Congress organizers to all the many Canadians who had helped to make the Congress such a success. After speeches from previous presidents, Dr. Best then announced that the Permanent Committee had accomplished its week's work and that an International Union of Physiological Sciences had been formed. The members of the Council of the new Union are Best (Canada) (chairman), Visscher (U.S.A.) (secretary), Adrian (Great Britain), Bykov (U.S.S.R.), Heymans (Belgium), Houssay (Argentine), Kuno (Japan), Lundsgaard (Denmark), Mayer (France), von Muralt (Switzerland), and Weber (Germany).

Dr. Houssay thanked our Canadian hosts on behalf of all the members of the Congress, and Dr. Best announced that the 1956 Congress would probably be held in Belgium, but that confirmation of the invitation was still awaited.

The plenary session was followed by a special convocation of the University of Montreal at which Cardinal Leger, as chancellor of the University, conferred honorary doctorates in medicine on Dr. E. D. Adrian (Cambridge) and Dr. L. Binet (Paris) (*in absentia*). Earlier in the week, at a special convocation of McGill University, the Chancellor, Dr. B. C. Gardner, had conferred honorary doctorates of science on Sir Henry Dale, Dr. E. Lundsgaard and Dr. W. R. Hess, all past presidents of Physiological Congresses. This convocation was held in the open air in Molson Stadium. In an address of thanks after the ceremony, Sir Henry Dale made a plea for "complete and confident freedom of communication" among scientists, and declared that national loyalties are not concerned with, and need in no way weaken, a common loyalty to the advancement of true knowledge in the sphere of our common interest.

On two evenings during the Congress, members were entertained by the City of Montreal at receptions in the Mountain Chalet on Mount Royal. Mayor Houde was an impressive host, and personally greeted every one of his guests—no mean achievement with a Congress of this size. One afternoon was left free of scientific meetings and was wholly devoted to a programme of excursions in Montreal and its environs.

The Congress proper was followed—with some overlap—by an international meeting of pharmacologists. Two sessions on September 4 were devoted to short communications, and on the following day two symposia were held at MacDonald College. The sun, having baked the physiologists, retired honourably on Saturday, and left the heavens to thunder clouds; the rain which resulted was every bit as whole-hearted as the heat had been. The morning was devoted to a session on the action of drugs at autonomic ganglia, with Dr. J. H. Burn in the chair. Papers were read by W. D. M. Paton (London, England) on types of pharmacological action at autonomic ganglia; R. Wien (London, England) on the relation of chemical structure of compounds to their action at autonomic ganglia; S. Marazzi (Maryland) on the action of adrenaline and the reciprocal action of acetylcholine on autonomic ganglia; N. Ambache (London, England) on autonomic ganglion stimulants; and D. Bovet (Rome) on central effects of ganglionic blocking agents. In the afternoon, the symposium had as its subject the pharmacology of renal tubular mechanisms, and papers were presented by I. Sperber (Uppsala) on competitive metabolism and specificity of renal tubular mechanisms; by J. V. Taggart (New York) on biochemical features and energy experiments of renal tubular transport; by K. H. Beyer (West Point) on factors basic to the development of useful inhibitors of renal transport mechanisms; by R. W. Berliner (Bethesda) on the effect of drugs on renal tubular transport of hydrogen ions and potassium ions; and by H. S. Heller (Bristol) on endogenous influences on renal transport mechanisms. The chairman of this symposium was Dr. A. N. Richards.

To bring the week to a fitting and final conclusion the pharmacologists gave a party in Montreal. The gaiety, nowhere more notably evident than in the after-dinner speeches, probably reflected the relief that it was all over. Thus did the tumult and the shouting die, and, in the silent watches of the night, Montreal was deserted by physiologists who crept away to their laboratories in forty-eight different countries of the world. And so to Belgium in 1956.

W. L. M. PERRY

THE ARMAMENT RESEARCH ESTABLISHMENT

THIS year is being celebrated as the golden jubilee of the oldest organization of its kind in Great Britain, the Armament Research Establishment of the Ministry of Supply. The history of the Establishment is essentially the story of the development of high-explosive munitions as we know them to-day and runs the whole gamut from the lyddite shell and its propellant—the unsatisfactory performance of both of which during the Boer War was largely responsible for the formation of the Establishment—to the atomic bomb.

Previous articles[1] in *Nature* have described the work of the Research Department, Woolwich (as the Establishment was then known), from its inception to the end of the First World War, but did not relate how it came into existence. It is proposed to give here a historical review and, so far as security restrictions permit, to describe some of the more important aspects of the Establishment's work since the date of the previous articles. The review will reflect the growing influence of the scientist in matters of defence and the change in emphasis from chemistry to physics in this field.

There existed in 1890 a Government Committee on Explosives, consisting of Sir Frederick Abel (president), Prof. (afterwards Sir) James Dewar and Dr. A. Dupré (all Fellows of the Royal Society). In February of that year this body reported as follows: ". . . the Committee are continually impressed with the great importance, and indeed the necessity, of . . . experimental investigations such as are carried on by Col. Sébert, who is one . . . of the members of the French Permanent Committee on Explosives, and they venture to urge most strongly the wisdom of so extending the scope of work . . . of the Government Explosives Committee as to add to its members an Artillery Officer having special scientific attainments (such as those possessed by Captain Holden) . . .". In its final report in 1891, the Committee said: "The Committee on Explosives . . . desire to impress upon those who will pursue this work from the point where they leave it, that unremitting systematic scientific investigation and practical experiment will be absolutely indispensable to the maintenance of that position".

On March 19, 1891, the above-mentioned Captain C. Holden, R.A., sent a memorandum to the Assistant Director of Artillery advocating the setting up of a department "free to carry out experiments only, and not trammelled by proof or other work, which has to be done against time". He pointed out that "the present time, the commencement of a new era, with the introduction of cordite, is an opportune one". As a result of these representations, some years later a small experimental establishment was set up at the Proof Butts at Woolwich. It must be emphasized that this establishment was a military one concerned primarily with ballistics, that is, gun pressures and shot velocities, and that no scientists were employed.

On April 6, 1900, Major F. L. Nathan, Superintendent of the Royal Gunpowder Factory, in a report to the Chief Superintendent of Ordnance Factories, said that he had "ventured to point out to the Director General of Ordnance on 31 March 1900 that our War Office is not abreast of those of foreign powers as regards machinery for systematic study in connection with explosives for military purposes and to suggest to him the desirability of appointing a small committee of experts to direct experiments and researches, and a staff for carrying them out".

On April 12, 1900, the Admiralty wrote to the Under-Secretary of State, War Office, stressing the urgency of obtaining a better propellant than the current form of cordite and expressing "their great disappointment at the very little progress made during the past year, as shown by the Annual Report of the President, Ordnance Committee. . . . They hope Lord Lansdowne may see fit to . . . expedite matters, either by the appointment of a special Committee or by an increase in War Office staff. . . . My Lords will be prepared to share in the cost of such extra staff or Committee". On April 19, Major Holden (as he then was) in his capacity as Superintendent of the Royal Gun Factory, also in a report to the Chief Superintendent of Ordnance Factories, suggested means for carrying out trials on propellants; in this report he referred to his proposals of nine years before. On April 21, the Chief Superintendent of Ordnance Factories forwarded Nathan's and Holden's reports to the Director General of Ordnance, who had asked him to ascertain their views on his (the Director General's) proposals for comparative trials between cordite and other smokeless powders. The Chief Superintendent of Ordnance Factories said that he agreed with the two officers that the only way of obtaining a better propellant than cordite was to go into the subject systematically from the beginning, starting with closed-vessel experiments and proceeding to rifles and guns. He recommended a small scientific committee to work at the problem "from day to day till the end was achieved".

On April 30, 1900, the Secretary of State informed the Director General of Ordnance that it had been decided to appoint such a Committee, and this body, known as the Explosives Committee, was set up in May of that year with Lord Rayleigh as president, and Sir Andrew Noble, Mr. R. B. Haldane (later Lord Haldane), Sir W. C. Roberts-Austen and Sir William Crookes as members. The Committee was to report to the Director-General of Ordnance, at the War Office, and its terms of reference were as follows:

"To carry out trials with a view to ascertaining what are the best smokeless propellants for use in existing guns of all natures and in existing small arms.

"To report as to whether any modification in the existing designs of guns is desirable, with a view to developing to the full the powers of any propellant which may be proposed.

"To carry out trials with a view to obtaining a high explosive for shells which can be fired from all natures of guns and howitzers with as much safety as lyddite, with greater certainty of detonation, and with greater explosive effect".

One of the first actions of the Explosives Committee was to recommend to the Director-General of Ordnance that a separate experimental establishment should be formed as soon as possible, to do original research on explosives and steels. The recommendation was accepted, and the War Office and Admiralty agreed to share the cost. Land was secured for the new establishment by extending the eastern boundary of the Royal Arsenal, Woolwich, in 1902, and a laboratory, an explosion chamber, a nitrating house and other facilities were ready for use in 1903 and are still in use to-day. It is this year, 1903, when the preliminary organization had been completed and the facilities provided were put into operation, that has been taken as the date of birth of the establishment.

Meanwhile, the Committee had arranged for the appointment of a young organic research chemist, Dr. O. J. Silberrad, who took office in January 1902 and who very soon afterwards became superintendent of chemical research to the Committee. Silberrad's first main task was to equip the new laboratory, and he was sent to Germany to study similar establishments there.

Under Silberrad's energetic guidance, a small staff of chemists applied themselves to improving propellants and to eliminating the causes of failure of our lyddite shells to detonate properly. The latter end was achieved by developing the use of the explosive trinitrophenyl-methyl-nitramine, which is still used to-day as the intermediary between detonator and main filling, under the name of tetryl.

The work on propellants included research into means of eliminating flash and into methods of manufacture requiring much less acetone.

Systematic research into metallurgical problems connected with armament may be said to have been initiated when Dr. H. Moore was appointed as chief metallurgist to the Chemical Research Department, as the Establishment was then known, in 1904; plans for a separate metallurgical laboratory had been submitted two years earlier.

The Explosives Committee ceased to function in 1906, having in the six years of its existence not only caused the Establishment to be formed but also through it laid the foundation of the modern design of 'conventional' high-explosive munitions. The Explosives Committee was succeeded by the Ordnance Research Board—not to be confused with the Ordnance Board—which sat under the presidency of Major-General D. D. T. O'Callaghan, only Sir William Crookes from the Explosives Committee retaining a seat on the new body. The Ordnance Research Board existed for only about a year before it was merged with the Ordnance Committee, as the present Ordnance Board was then called.

Shortly after the Explosives Committee was disbanded, Dr. Silberrad resigned; he was succeeded as superintendent by Dr. R. Robertson, who was appointed early in 1907 and who remained with the Establishment for the next fourteen years until, as Sir Robert Robertson, he resigned his post of director of explosives research to become Government Chemist.

In April 1907 a radical change took place. The Chemical Research Department and the Proof and Experimental Establishment at Woolwich, which had been concerned with the proof of guns since the seventeenth century, were amalgamated to form the Research Department, Woolwich, under a military superintendent, Major J. H. Mansell, R.A. The Superintendent reported to the Master General of Ordnance through the Director of Artillery. Dr. Robertson became assistant superintendent (chemical research), and Captain Howarth, R.A., assistant superintendent (mechanical research). Dr. Moore, however, assumed the latter office a year or two afterwards. Thus began the direct Service control of the Establishment, which was to continue until 1942, the Service heads being drawn alternately from the Army and the Navy.

Under Silberrad, Robertson and Moore, the scientific work of the Establishment was put on a firm basis, with the results, so far as the first twenty years are concerned, described in the articles referred to earlier.

In the early years of the inter-war period, about 150 scientists were employed in four directorates: Explosives Research (Dr. G. Rotter), Ballistics Research (Dr. (now Sir) Alwyn Crow), Metallurgical

Research (Dr. H. Moore and, from 1932, Dr. R. H. Greaves) and Radiological Research (Mr. V. E. A. Pullin). Much effort at this time was devoted to solving problems thrown up by the First World War, notably the need for stabilizing the older types of cordite and nitro-cellulose powders which, owing to the inclusion of small particles of foreign matter, particularly sulphur, were liable to explode spontaneously; the loss of the battleship *Bulwark* in Sheerness Harbour was probably a result of this serious defect. The cause of such explosions was found to be heat developed at corrosion spots caused by the inclusions; the remedy was to replace all or part of the mineral jelly in the cordite by carbamite, that is, *sym.* diphenyl diethyl urea.

War-time cordites were irregular in dimensions, and therefore in ballistics, owing to the use of volatile solvents in their manufacture and the consequent need for long periods of stoving. By developing a solventless cordite, the Department was able not only to produce sticks of uniform size but also to introduce such checks in manufacture as to enable the energy content to be accurately controlled. The need for expensive gun proof was thereby very much reduced. Simultaneously with these steps to improve propellants, there was instituted a system of '100 per cent surveillance', using specially developed test-papers, of the large stocks of potentially dangerous cordite in all parts of the world.

These improvements in propellants marched hand in hand with advances made by the Department in the science of ballistics, which enabled full use to be made of their potentialities. Thus, not only in ballistic theory but also in ballistic instrumentation, notable progress was made, including new methods of measuring the pressure and strain in guns, and the velocity of projectiles. The Ballistics Directorate was also busy studying the controlled burning of cordite, enabling cordite engines to be used for such non-lethal purposes as the launching of aircraft and the starting of turbine engines. An important development arising from these studies was the anti-aircraft rocket, propelled by cordite; this was the subject of intensive research from 1935 onwards. Its potentialities had been largely established by 1938, in which year prototypes were produced and tested in Jamaica. As a result, a new establishment, the Projectile Development Establishment, under Dr. Crow, was formed in 1939 to develop them for use in the Services. Dr. Crow was succeeded as superintendent of ballistics research by Dr. C. A. Clemmow.

In the high-explosives field, the inter-war years saw the production by the Research Department of a new filling for armour-piercing shell and a delay-action fuze to go with it, thus providing for the Navy a shell which would not detonate harmlessly on impact with a ship's side, as happened with many British shells at the Battle of Jutland, but would penetrate before detonating.

Meanwhile, in the organic branch, the search was going on for a more powerful high explosive than TNT for shell and bomb fillings. After careful and extensive examination of some hundreds of possible compounds, choice was narrowed down to two, tetranitropentaerythrite (PETN) and *cyclo*trimethylenetrinitramine (cyclonite or RDX). Of these, RDX was finally chosen and, in admixture with desensitizing agents—it was too sensitive to be used alone—was widely used in the Second World War, forming the basis of the torpexes, minols and other fillings used in shells and bombs and of the plastic explosive used by the Royal Engineers for demolitions and for sabotage purposes.

In the metallurgical field, the Research Department built up a name for itself through various fundamental researches, many of which had industrial as well as armament applications. Some of the basic work was done with the assistance of grants from the Department of Scientific and Industrial Research. Of the outstanding subjects of investigation in the period under review may be mentioned the improvement of gun forgings to give higher yield strength, temper-brittleness of alloy steels, erosion and wear of gun barrels, and season-cracking of brass and its prevention. Researches in conjunction with the British Non-Ferrous Metals Research Association led to the development of the aluminium–brass condenser tube and the ternary lead alloys for cable sheathing. Much work was also done by the Department on electrodeposition repair processes, which led to the use of electrodeposition for repairing the liners of worn guns and for increasing the life of new guns, with enormous gains in economy.

Radiographic methods were first used in armament research in 1917, and the period between the two World Wars saw the development of radiological methods as an established procedure for investigation and inspection. Mobile sets were constructed for the examination of heavy steel castings and welded structures for the Admiralty, and explosives and propellants were examined for cavities and fissures. Magnetic methods were introduced for the detection of fine cracks in steel forgings and castings. Attention was also paid to X-ray crystal analysis methods of determining grain size and the extent of annealing and cold work.

In this period also, notable advances were made in pyrotechnics, a field in which the Research Department was, and still is, pre-eminent.

When war broke out in 1939 the immediate problem to be faced was shortage of supplies, and the Department's main task was to alleviate or remove production difficulties and to give advice to the Services and the ordnance factories. These tasks were to some extent rendered easier by the planned dispersal of the staff on the outbreak of war to some thirty outstations at ordnance factories, universities, technical colleges and country mansions; but in other ways this dispersal caused grave dislocation.

In 1942, however, following a recommendation of the Guy Committee, reorganization and a degree of recentralization took place. Responsibility for the Research Department had passed in 1939 from the War Office to the newly formed Ministry of Supply, and it was a logical step, and a recognition of the place of the scientist in modern war, that the Guy Committee should also recommend that the direction of the Department should be vested in a civilian scientist. Prof. (now Sir) John Lennard-Jones was appointed chief superintendent (armament research) in that year, and the headquarters of the Armament Research Department, as the Department was renamed (it assumed its present title in 1948), was moved from its evacuation station at Shrewsbury to Fort Halstead, alongside the Armament Design Department. It is interesting to note that the new station had originally been built for the Research Department's daughter establishment, the Projectile Development Establishment, which meantime had moved to Aberporth in Wales.

Thus the wheel had moved full circle, and after thirty-five years a scientist was again at the head of the Department's affairs. That this is proper in existing circumstances cannot be denied; but tribute must be paid to the efforts of a series of enlightened Service chiefs who, often in the face of opposition, upheld the cause of the Department and its work.

The achievements of the Second World War cannot all be recounted, for obvious reasons, but mention can be made of the incendiary small-arms ammunition, using the Research Department's filling, which was so effective in the guns of the Hurricanes and Spitfires in the Battle of Britain; and of the various hollow-charge projectiles, which were based on the fact (the Neumann or Monroe effect) that an explosive charge which is coned out at its forward end has, rather paradoxically, much greater penetrative effect against a target than a cylindrical charge.

The inferiority of British tank armament, in the early and middle stages of the War, to that of the Germans is well known; but it may not be so well known that the position was reversed when the British 'sabot' projectile, developed in collaboration with the Armament Design Department, came into use and drew from the War Office a telegram "One shot—one tank—can't miss", after the D-Day landings. The principle of the 'sabot' is that a small but heavy and hard shot is centred in a gun of larger diameter than the shot by means of a segmented and therefore weakened collar (the 'sabot') which, when the combined projectile emerges from the gun, breaks up and separates from the shot through the action of the centrifugal force due to the spin. The shot, with the very high velocity imparted to it by the large gun, and a correspondingly high penetrative power, then proceeds alone on its mission.

The need for large blast bombs for the attack on Germany led to the development of the 'aluminized' explosives, formed by mixing high explosive with powdered aluminium, which greatly increases the blast effect. Bombs with such explosives were used in the attacks on the Ruhr dams and the battleship *Tirpitz*. Target indicators and photoflash bombs were also developed for the R.A.F.

For the inspection departments and firms engaged on munition production the metallurgical branch provided advice and assistance on a multitude of problems.

Much of the work of an establishment like the Armament Research Establishment is inevitably of a consultative and advisory nature, and this is particularly so where safety problems arise. It is largely due to the accumulated experience of the Establishment that British munitions are second to none in safety of handling and operation.

The investigation of the cause of accidental explosions often involves the scientific and other staff concerned in situations of extreme personal danger. Such duties have never been shirked, and it may be mentioned that just after the War Dr. G. Rotter was awarded the George Medal and Mr. S. W. Maxted was appointed M.B.E. for extremely hazardous and protracted underground work following a very large explosion in an ammunition depot. More recently, five members of the staff have received the Queen's Commendation for Gallantry in connexion with an explosion in Woolwich Arsenal. During the War, mobile teams radiographed unexploded enemy bombs and fuzes in order to assist the bomb disposal units in their hazardous task. Mr. W. J. Wiltshire, Mr. D. E. Barnes and Dr. J. A. T. Dawson received the George Medal for gallantry in the course of this work.

A most important war-time development was the creation in 1943 of a branch for theoretical research, comprised first of all of mathematicians but recently expanded to include physicists and engineers to operate new facilities erected at Fort Halstead for the study of problems in aerodynamics and hydro-ballistics. To-day the Applied Mathematics and Mechanics Division possesses a supersonic wind tunnel, a cavitation tunnel, a tank for studying the motion of projectiles on and after entry into water, and a high-speed electronic computer with which it will provide a computing service for the whole Ministry as well as for the Establishment.

The Establishment's war effort on both occasions was increased by the temporary employment of scientists drawn from the universities or elsewhere, and many such who are household names in the scientific world have at one time or another been colleagues of the regular staff.

Just as after the First World War, so after the Second, there were changes in the organization. Thus in 1946 the mainly chemical aspects of the Establishment's work were detached and assigned to a new body, the Explosives Research and Development Establishment at Waltham Abbey, which thus became the Armament Research Establishment's second daughter establishment. In that year, too, Prof. Lennard-Jones, who had been knighted for his services, resigned and was succeeded by Dr. (now Sir) William Penney as chief superintendent. Shortly afterwards, the Department was given the vital task of developing Britain's first atomic bomb, under the code-name of 'H.E.R.' (High Explosives Research). As the project grew, it became necessary once again to form a separate establishment, the Atomic Weapons Research Establishment, from the Armament Research Establishment, which this time was called upon to make an even greater sacrifice than on the two previous occasions, since it gave not only its chief superintendent and a large number of its most experienced staff to the new body but also buildings, including its headquarters offices. New headquarters were set up at Woolwich, where some sections which could not be evacuated had remained throughout the War.

When the new buildings for atomic work at Aldermaston are finally completed, the laboratories at Fort Halstead erected for 'H.E.R.' will become available to the Armament Research Establishment, which will therefore recover something of what has been lost; but it will be some time before the inroads made into the staff are made up and the still vitally essential work on more conventional weapons can proceed with full effect.

Under the present chief superintendent, Dr. H. J. Poole, the Establishment is, however, now building up again as rapidly as conditions permit. With its programme of basic researches in the fields of mathematics, metallurgy, physics, chemistry and ballistics; with close contacts with the universities through common membership of committees of the Ministry's Scientific Advisory Council, and a policy of permitting publication whenever security considerations permit, it can offer a satisfying and useful career to scientists in any of the fields mentioned, as well as in engineering. The Establishment looks to the next fifty years with confidence.

At a dinner to celebrate the golden jubilee of the Establishment, held at the Goldsmiths' Hall on November 27, the Minister of Supply, the Right Hon. Duncan Sandys, was the principal guest.

---

OBITUARIES

Prof. T. Thunberg

WITH the death of Torsten Thunberg on December 4, 1952, there passed an investigator whose name was known to generations of physiologists and biochemists, and whose 'Thunberg tube' has served a valuable purpose in the study of dehydrogenase reactions. It was undoubtedly as a biochemist that Thunberg made his major contributions to science.

Born in 1873, Thunberg, after training in medicine, became a demonstrator for one year in the Institute of Physiological Chemistry at Uppsala under Olof Hammarsten, and for two years under Frithiof Holmgren, in the Institute of Physiology. In 1897 he was appointed temporarily as reader in physiology at Uppsala, in which post he was confirmed in 1901 at the early age of twenty-eight. After the death of Magnus Blix in 1904, Thunberg became the temporary occupant of the chair of physiology and embryology at Lund, and in the following year he was appointed substantively to the chair of physiology, a post which he retained until his retirement in 1938. On his retirement he was appointed professor emeritus, and he continued to make contributions until the time of his death, his last paper being published early this year.

Although in his early years Thunberg's researches extended as far as the physiology of the senses, including colour blindness, it was for his investigations on dehydrogenases, and on the metabolic significance of citric acid, that he is best known. When he began his studies on intermediary metabolism, little was known about the mechanism of oxidation within the cells. In 1885 Paul Ehrlich's book, "Das Sauerstoffbedürfnis des Organismus", described the staining of tissues by the *intra vitam* injection of dyes such as methylene blue, and stated that some tissues could reduce suitable injected dyes to colourless leuco-bases; but little came of these observations at the time. In 1912 Wieland showed that organic substances can be oxidized by the removal of hydrogen in the presence of a catalyst, and that the hydrogen could be taken up by suitable acceptors, such as methylene blue, which were thus reduced to the colourless leuco-base. Thus, the oxidation of ethanol to acetic acid could be formulated in terms of the activation and removal of hydrogen atoms. In his own studies, Thunberg had investigated the capacity of animal tissues to oxidize acids such as acetic, propionic, oxalic, malic, succinic and citric acids, and it was perhaps intuition which led him to choose, from all those available, acids such as succinic and citric, the especial importance of which in metabolism is now clearly recognized.

In 1910 Thunberg found that the addition of succinate to minced muscle resulted in an increase in oxygen uptake, and later integrated his own with Wieland's discoveries in propounding the idea of a specific hydrogen-activating, chain-forming enzyme system in the oxidation of succinate. A dehydrogenase, such as succinic dehydrogenase, could activate hydrogen atoms in its substrate to bring about a reaction which otherwise could not be observed, namely, the reduction of methylene blue to the colourless leuco-base; this colourless leuco-base could in turn be reoxidized to methylene blue by atmospheric oxygen. The introduction of the terms 'hydrogen donator' and 'hydrogen acceptor' in this connexion were of the widest significance, and opened up the possibility of the existence of a multitude of hitherto unsuspected dehydrogenases. The ideas that developed from this work appeared to be contrary to that of Warburg's 'respiratory enzyme' in some respects; but later Warburg's own 'yellow enzyme', a hydrogen-carrying flavo-protein, helped to bridge the gap, and to-day Thunberg's concept of hydrogen transport from one system to another lies at the root of modern views on oxidative metabolism.

In 1910 Thunberg suggested that citric acid represented a normal intermediary in metabolism and he was afterwards able to map out the occurrence of citric acid in animals and man. The recent development of the citric acid cycle, first through the researches of Szent-Györgyi on the catalytic significance of succinic acid in biological oxidation, and then through the addition of tricarboxylic acids to complete the cycle, which was the work of Krebs, bears witness to the far-sightedness and soundness of Thunberg's ideas. With Thunberg's death biochemistry has lost one whose contributions are securely placed within the foundations of modern views on intermediary metabolism in general and of the mechanism of cellular oxidation in particular.

Vol. 30, Supp. 111, of *Acta Physiologica Scandinavica* contains an obituary notice of Thunberg with a bibliography of his papers. F. G. YOUNG

Mr. L. St. L. Pendred, C.B.E.

THE news of the death on November 20 at Twickenham of Loughnan St. Lawrence Pendred, for forty years the editor of *The Engineer*, will be read with regret by engineers all over the world. Together with *Engineering*, *The Engineer* is read wherever engineers congregate, both journals being known for their high professional standard and the sense of responsibility shown by a succession of able editors. Founded in 1856 by Edward Healey, *The Engineer* was edited for a short time by the brilliant but eccentric American engineer Zerah Colburn (1832–70), who in 1866 founded *Engineering*. Colburn was a nephew of the famous American 'calculating boy', Zerah Colburn (1804–40), and is sometimes confused with him. Colburn's connexion with *The Engineer* ceased in 1864, and shortly afterwards Vaughan Pendred (1836–1912) was appointed editor. A native of Barraderry, Co. Wicklow, Vaughan Pendred in 1862 had married Marian Loughnan, of Crohill, Co. Kilkenny, and a year or two later had settled in England, obtaining through Colburn an appointment in a works in Staffordshire. A classical scholar, a lover of mechanics and a born journalist, he became first the editor of the *Mechanic's Magazine*, and then in 1865 editor of *The Engineer*, a position he held until his retirement in 1905.

Loughnan Pendred was one of Vaughan Pendred's three sons. Born on November 23, 1870, he received his technical education at the Central Institution, South Kensington, and Finsbury Technical College, where he came under the influence of Silvanus Thompson, John Perry and H. E. Armstrong. Leaving college, he served an apprenticeship with Davey, Paxman and Co., of Colchester, and gained further experience in Belgium and France, and during 1893–96 he worked in the ordnance department of Armstrong's great works at Elswick. In 1896 he joined the staff of *The Engineer*, and nine years later succeeded his father as editor. Long a member of the Institution of Mechanical Engineers, he was president during 1930–31 and represented the

Institution at the jubilee meetings of the American Society of Mechanical Engineers. In 1934 he delivered the Thomas Lowe Gray Lecture of the Institution, taking as his subject "A Survey of Ships and Engines".

Having guided the fortunes of *The Engineer* during two world wars and the great depression of the '30s, Pendred resigned his editorship in 1946 and was succeeded by his second son, Benjamin Pendred, who had joined the staff in 1931. During the First World War, Pendred was editor of *The Ministry of Munitions Journal*, and for this and other services to engineering, in 1934 was created C.B.E. The Institution of Mechanical Engineers also made him an honorary member.

Always interested in the history of engineering, Loughnan Pendred played an important part in the inauguration in 1920 of the Newcomen Society, and it was at a dinner given by him to some of its founders, at the Savage Club, then housed in the Adelphi, that the name of Thomas Newcomen was adopted for the new Society. Pendred was one of the original members of council and during 1922–24 and 1928–30 served as president; on October 26, 1923, delivering a stimulating address on "The Value of Technological History". Among his other contributions to the *Transactions* of the Society was a scholarly address given in Dartford Parish Church on the occasion of the commemoration on April 23, 1933, of the centenary of Richard Trevithick. Other societies with which he was connected include the Iron and Steel Institute, the Junior Institution of Engineers, of which he was an honorary member, and the Institution of Engineers-in-Charge, of which he served as president. In an appreciation of Pendred when he retired, Mr. G. E. Chadwyck-Healey, a grandson of Edward Healey, wrote: "I count myself fortunate in having had so kindly, wise and steadfast a friend". There are others who will feel the same.

EDGAR C. SMITH

Mr. A. B. Broughton-Edge, M.B.E.

MR. ARTHUR BROUGHTON BROUGHTON-EDGE, who died on October 8 after an illness which dated from 1940, was a man of very wide interests, demonstrated by his membership of the Institution of Mining and Metallurgy, the Chemical Society, the Mineralogical Society, the Geological Society and the Geologists' Association. His main concern, however, was in geology and the use of geophysical methods in the search for minerals, and in this latter branch he was one of the early pioneers. Born on March 16, 1895, and educated at Bradfield College, Berks, he joined the University and Public Schools Corps at the outbreak of the First World War. Later, commissioned in the Royal Artillery, he saw active service in France, Salonika, etc., with an Indian Mountain Battery. He was invalided to England after an injury in Greece and spent the last part of the War investigating poisonous gases and, as a result, himself suffered from their effects. This phase of his career, for which he was made M.B.E., may well reflect his early interest in chemistry.

In 1918, however, Mr. Broughton-Edge entered the Royal School of Mines and studied geology, in particular the geology of mineral deposits, under Prof. C. G. Cullis, obtaining an A.R.S.M. in 1921 and a B.Sc. in 1922. As a student he visited Cyprus and was a joint author with Prof. Cullis of an authoritative work on "The Cupriferous Deposits of Cyprus", ultimately published in 1926. Although he studied numerous types of mineral deposits in many parts of the world and was active in the examination of old mineral fields of Great Britain, he will be mainly remembered for his early investigations into the use of geophysical prospecting methods in the search for minerals. In 1925 he was experimenting in Africa with electrical methods, and this valuable experience naturally led in 1928 to his appointment as director of the Imperial Geophysical Experimental Survey in Australia. The report of this survey, which was jointly financed by the Empire Marketing Board and the Australian Government, did much to remove the mystery which surrounded the procedures at that time and placed them on a sound scientific basis.

In 1935 he married Muriel Docea Pullman, who nursed him devotedly during his illness until her untimely death in 1947. Mr. Edge's fortitude during this period was outstanding and, despite his obvious handicaps, he investigated the uses of the microscope for special mineralogical problems, the results of which will be published posthumously.

Mr. Robert Donaldson

THE sudden death on November 5 of Robert Donaldson has deprived physical optics of one of its well-known workers. Born in 1904, he obtained a first in his M.A. in the University of Edinburgh and, after two years as demonstrator in the Department of Natural Philosophy there, went to the National Physical Laboratory in 1928. He was, in those days, as much a mathematician as a physicist and was specially fitted for the post of assistant to John Guild, then conducting his classical researches in the measurement of colour. This early work set the pattern for all that followed for, except during the war years, when he participated in the general work of the Light Division of the Laboratory, Donaldson was primarily occupied with the field of colorimetry, heterochromatic photometry and spectrophotometry.

In 1933 he became head of the colorimetry section of the Division and made outstanding contributions to the subject by the design of instruments and the development of new techniques; by investigating problems arising from the commercial introduction of new illuminants and colorants, for example, fluorescent lamps and paints; by providing the experimental data, apparatus and methods for new applications of colour in the medical field, such as colorimetric hæmoglobinometry and spectrophotometric tests for vitamins; and by the improvement of the standardizing procedures called for by the many specifications now governing the supply of lights and filters for rail and road signalling, marine and aerial navigation, aerodrome lighting, etc. Donaldson had a special aptitude for getting to the roots of a research problem, and this is well shown by a few examples of some of the instruments which bear his name.

The first trichromatic colorimeter designed at the National Physical Laboratory was intended primarily for the researches in the Laboratory which led to the establishment of the present international system of colour standardization. It required a supply of direct current and so proved inconvenient for use in industrial laboratories, many of which had only a public supply of alternating current available. Donaldson designed a colorimeter in which the blending of the trichromatic stimuli is effected by an integrating sphere, and which can be used with either A.C. or D.C. supply. This instrument is now the most widely used trichromatic colorimeter in the English-speaking countries.

A trichromatic colorimeter, though the fundamental instrument for colour measurement, gives results which depend to an appreciable extent on the colour vision of the observer. To minimize these variations, it has to employ a small visual field, which is a disadvantage for industrial or commercial applications. To meet this difficulty, Donaldson designed an instrument on the same lines as his trichromatic colorimeter but with three additional matching colours, making six in all, which when calibrated and used in the proper way gives results characteristic of the C.I.E. 'standard observer', unaffected by any but very gross visual abnormality of the actual user. It can be used with a large matching field, giving much greater precision than the small field of the trichromatic instrument. This colorimeter has proved most valuable in work at the National Physical Laboratory and has recently been made available commercially.

For many purposes, particularly in a standards laboratory, a colorimeter in which the eye of a human observer is replaced by a photo-cell or other detector of light is of great value. It not only avoids fatigue of observing staff but also gives results which are not limited in precision by visual sensitivity or affected by visual abnormalities. The physical detecting system must, of course, be arranged to evaluate light in exactly the same way as the accepted 'standard observer'. There are several ways of doing this—by filters or by templates fitted in a spectrometer, the filters or templates being made in relation to the spectral response of the photocell so as to give the required resultant spectral response for the combination. Donaldson designed a template colorimeter before the Second World War but, unfortunately, before it could be constructed the war-time claims on workshop facilities caused abandonment of the project until the return of peace. Other template colorimeters were developed commercially in the meantime; but none of these is capable of the highest class of work. Donaldson's instrument was designed with that end in view. It was constructed after the War and appears to provide a complete solution to the problems of exact physical colorimetry and heterochromatic photometry.

In addition to the foregoing, Donaldson was responsible personally or in a supervisory capacity for the design and development of numerous instruments and devices required for use in the National Physical Laboratory, such as photoelectric spectrophotometers for the visual and ultra-violet ranges, comparators for the calibration of hæmoglobin test-tubes, double monochromators with single optical train, and so on, including, in collaboration with Stiles, the design of the multiple spectroscopic colorimeter now under construction for the forthcoming redetermination of the properties of the 'standard observer'.

At the invitation of the Medical Research Council he collaborated with a team of pathologists and biochemists in setting up a system of standardized colour tests for hæmoglobin determinations. He was responsible for the investigation of the relation between the oxygen-carrying capacity of hæmoglobin with its iron content and spectral absorption. His results, obtained from an analysis of blood samples from representative groups of male and female subjects, have established a norm for the hæmoglobin content of human blood which is now the standard by which all test apparatus is calibrated.

Donaldson's scientific abilities were recognized a few months ago by his special promotion to the grade of senior principal scientific officer. His personal gifts were rewarded by the respect and affection of all his colleagues; modest and unassuming himself, he had a keen sense of humour and an understanding for the failings of others. His tastes were simple and he had a true Scotsman's delight in a game of golf. His sudden death has robbed his colleagues and many friends of one who merited their affection and esteem.

L. A. Sayce

We regret to announce the following deaths:

Dr. Herbert E. Ives, member of the U.S. National Academy of Sciences, formerly of the Bell Telephone Laboratories, aged seventy-one.

Dr. T. W. Lumsden, director of cancer research in the London Hospital, 1930–42, aged seventy-eight.

NEWS and VIEWS

P. P. E. Roux (1853–1933)

Born at Confolens, Charente, a century ago, on December 17, 1853, Pierre Paul Émile Roux began his medical studies at Clermont-Ferrand, where he attracted the attention of Émile Duclaux, whom he was to succeed as director of the Pasteur Institute at Paris in 1904. His friendship with Pasteur began in 1878, when he started working in the old laboratory of the École Normale Supérieure. Like his master, Roux possessed a real genius for finding brilliant men and drawing out their best qualities. Self-effacing and hating publicity, he gave many of his most enduring contributions to the world under the name of a colleague. He amplified Pasteur's work on attenuation, chicken cholera, vaccination of sheep and cattle against anthrax, and rabies. In collaboration with Elie Metchnikoff, he succeeded in inoculating anthropoid apes with syphilis, and introduced the prophylactic use of calomel ointment. In 1888, Alexandre Yersin and he isolated the diphtheria toxin by passing a culture through a porcelain filter, thus paving the way for Emil von Behring's discovery of the antitoxin. Roux's announcement in 1894 at the International Congress of Medicine in Budapest that the antitoxin possesses both prophylactic and therapeutic value caused a sensation in medical and lay circles. As a teacher, Roux was lucid, concise and graphic, and pupils from all over the world attended his bacteriology courses. His numerous scientific honours included the foreign membership of the Royal Society in 1913 and the Copley Medal in 1917. Though in his later years everyone knew the tall, gaunt, ascetic man with the hollow cheeks and sallow complexion, who occupied the most honoured place in the world of bacteriology, few really knew him well. A sufferer from chronic pulmonary tuberculosis for thirty years, Roux died on November 3, 1933. His obituary in *Figaro* had been written by his colleague, Albert Calmette who died a few days before him.

Jubilee of Powered Flight

ORVILLE WRIGHT's first successful powered flight occurred fifty years ago on December 17, 1903. Man's age-old ambition to fly had culminated in considerable aeronautical activity during the last quarter of the nineteenth century. Ballooning had been well established before this, and there remained the mastery of 'heavier-than-air' flight. Lilienthal and Pilcher had made precarious flights in gliders of various bird-like shapes and had ultimately perished. Octave Chanute, president of the American Society of Civil Engineers and builder of the first bridge over the Missouri, had invented—and flown—the biplane arrangement of the wings of his glider. Lanchester and Langley had flown stable model 'aerodromes', the latter's including steam-powered tandems which were capable of speeds in excess of 30 m.p.h. However, Langley's man-carrying machine had fallen into the Potomac River immediately after being catapulted from a houseboat on December 8, 1903. This concluded the heartbreaking story of seventeen years of scientific effort by the secretary of the Smithsonian Institution and his associates. It is evident that some of the Wrights' contemporaries were very close to success at that time, but none of them had the Wright brothers' combination of the gifts of scientific appreciation of evidence, design ingenuity and ability to make apparatus with their own hands. They carefully analysed Lilienthal's results and then gave their attention to three problems: the provision of adequate lift with stability, of thrust and of control. They studied the first with a home-made wind tunnel and built their own 12-b.h.p. internal combustion engine. They developed their own propellers and achieved the then remarkable efficiency of 66 per cent. Their wing-warping system of lateral control was a crucial advance upon what had gone before, but it is the overall achievement that these men are best known for. They were mechanics in the best sense of the term.

A special exhibition commemorating the jubilee will be opened at the Science Museum, London, S.W.7, on December 15 and will remain on view for about three months (admission free). Models, books, aeronautical relics and diagrams will be displayed illustrating early contemporary thoughts and ideas on powered flight by a man-carrying machine, and how this was ultimately achieved by the Wright brothers. The *National Geographic Magazine* of December contains an article on the work of the Wright brothers with several historical photographs.

Natural Philosophy at Edinburgh:
Prof. M. Born, F.R.S.

PROF. MAX BORN, who has recently retired from the Tait professorship of natural philosophy at the University of Edinburgh, succeeded Sir Charles Darwin in that chair in 1936, when the latter was appointed Master of Christ's College, Cambridge. He had previously been *Professor Ordinarius* at Göttingen, where he was head of the world-renowned school of theoretical physics, which with Bohr's Institute for Theoretical Physics at Copenhagen played such a large part in the development of the quantum theory and its applications in the period between the two World Wars; while headed by Prof. Born it was, like Bohr's Institute, a place of pilgrimage for all those working in this field of theoretical physics. In 1933 the rising tide of Nazism in Germany drove him to leave Göttingen, and he went to Cambridge as lecturer in the Faculty of Mathematics; he was appointed Stokes lecturer in applied mathematics in 1934, and held this post until his appointment to Edinburgh. He was elected a Fellow of the Royal Society in 1939. Both by his own work and through the stimulus, encouragement and help which he gave to others, Prof. Born has had considerable influence on progress in various branches of theoretical physics, notably in the dynamics of crystal lattices, in quantum theory both in its general aspects and in its applications to particular systems, and latterly in the theory of the structure and properties of liquids.

Prof. N. Kemmer

PROF. N. KEMMER, who succeeded Prof. Born at Edinburgh at the beginning of the current academic year, was, like his predecessor, Stokes lecturer in applied mathematics at Cambridge before his appointment to Edinburgh. He has studied abroad for a considerable period, and holds the degree of D.Phil. of Zurich. He was appointed a lecturer in the Faculty of Mathematics at Cambridge in 1946, and was elected to a fellowship at Trinity College in the same year; he was appointed Stokes lecturer in 1949. He has been a member of the Board of the Faculty of Mathematics, and is interested both in teaching and research in mathematical physics. His main lines of research interest are quantum theory and its applications, especially nuclear theory and, more recently, quantum field theory and quantum electrodynamics. In this field he has been one of the leaders of a vigorous group of investigators at Cambridge, and has had a number of research students working under his direction.

Geology and Mineralogy at Trinity College, Dublin:
Dr. W. D. Gill

DR. W. D. GILL has recently been appointed to the chair of geology and mineralogy in Trinity College, Dublin, which became vacant last year on the death of Prof. L. B. Smyth (see *Nature*, 171, 196; 1953). Graduating in 1938 from the University of Leeds with first-class honours in geology, Dr. Gill joined the Attock Oil Co., Burma, and, working as a micro-palæontologist and field geologist, was a member of a small team which discovered many new prospects for oil. Specializing on the Siwalik Series in the Northern Potwar, he also discovered new foraminifera in Eocene formations. He joined the staff of the University of Nottingham in 1948 and became responsible for the development of photogrammetry in the Department of Geology and the establishment of a flourishing school of research on the micropalæontology of the Jurassic and Cretaceous rocks of Lincolnshire and Yorkshire. Using published and original material, Dr. Gill synthesized the structure and mechanism of mountain building in the frontal Himalayas. He takes to Trinity College, Dublin, a great store of new material and an enthusiasm for geological research in every field of the subject, and especially in structural and stratigraphical studies.

Expansion of the Department of Scientific and Industrial Research during 1954–59

THE principal effects of the recent announcement by Sir Ian Heilbron about the future development of the Department of Industrial and Scientific Research (see *Nature*, December 5, p. 1029) will be to enable the post-war plans of the Department to be completed. Decisions have still to be made on the actual allocations of the increased funds available. The income of the Department is expected to increase by £400,000 during 1954, the present income being approximately £5 million. Subsequent increases will bring the Department's vote to about £6 million by 1959, an increase over the five years of about 20 per cent. Another important change in the financial arrangements for the Department is that money not spent in any given year may, subject to the necessary funds being voted by Parliament, be carried forward for use in the following year. The Department's planning of research will thus be much more flexible than hitherto, when money unspent at the end of the year has had to be surrendered. Recruitment of staff will recommence at the rate of a hundred and fifty non-industrial staff yearly, and about one-third of that number of industrial staff each year. Apart from the afore-mentioned increases, a further sum of £6 million will be available to the Department for use during the period in the erection of new buildings. The original building plan for the Mechanical Engineering Research Organization at East Kilbride, Glasgow, will now be completed, and the new Road Research Laboratory, necessitated by the expansion of London Airport, will now be built, as also will be the new Ship Tank at the National Physical Laboratory, Teddington. The Hydraulics Research Station, Wallingford, the Water Pollution Research Laboratory, Stevenage, and the Radio Research Station, Slough, will be completed.

Parliamentary Responsibility for Atomic Energy

In reply to further questions in the House of Commons on November 26, the Prime Minister said that the Lord President of the Council will be responsible for the government atomic energy establishments from January 1. The Lord President will, therefore, be responsible for ensuring that the results of research in the universities are taken into account in the work of the government atomic energy establishments. Research by the universities is, of course, carried out on their own responsibility and is mainly of a fundamental nature; but the atomic energy organization places contracts with the universities in connexion with specific research inquiries. The Prime Minister had already indicated, on November 19, that when the new system comes into operation questions relating to the responsibilities transferred from the Ministry of Supply to the Lord President of the Council would be answered by the Minister of Works. He now states that the questions of atomic energy cover so wide a field that purely technical and scientific questions only will be dealt with by the Minister of Works, while others may have to be answered by the Foreign Secretary or by himself.

Fluoridation of Water

In a written reply to a question in the House of Commons, the Minister of Health, Mr. Iain Macleod, has announced that the Government has decided to accept the recommendations of the mission which recently visited North America to study the fluoridation of domestic water supplies as a means of controlling dental caries. The Minister, in conjunction with the Minister of Housing and Local Government, who is responsible for public water supplies in England and Wales, and the Secretary of State for Scotland, proposes to arrange for studies to be made in some selected communities of the various aspects of the fluoridation of water supplies before considering whether fluoridation should be generally adopted in Britain. An approach will be made to certain local authorities to invite their co-operation in making these studies.

Yorkshire Dales National Park

The chairman of the National Parks Commission (Sir Patrick Duff) has signed the Yorkshire Dales National Park (Designation) Order; this is the seventh National Park to be designated. The Order will be submitted in due course to the Minister of Housing and Local Government for confirmation. The area, which comprises a total of approximately 680 square miles, lies wholly within the North and West Ridings of Yorkshire. The boundary is broadly similar to that proposed in 1947 in the Hobhouse Report, though certain changes have been made, notably the addition of some 80 square miles in Sedbergh Rural District, including Dentdale and the Howgill Fells. The proposed National Park contains a wide variety of landscape which includes not only the most picturesque parts of the famous Dale country, but also some of the finest limestone scenery in Britain. From Bolton Abbey in Wharfedale, it extends northwards, through Malham with its impressive Cove, and the Gordale Scar—to Ribblesdale and the mountains—Ingleborough, Whernside and Pen-y-Ghent. Continuing northwards through upper Wharfedale with its many charming villages from West Witton to Garsdale Head, the Park extends across to Swaledale and the outskirts of Richmond, and north-west to Arkengarthdale and Bowes Moor.

The Development of Canada

During November 13–14 a conference was held in Quebec city under the title "Canada's Tomorrow". The proceedings of this conference comprised the presentation and discussion of eight papers which surveyed the whole Canadian scene and assessed from a set of rather fundamental points of view the country's position in the world and the possible directions of its future development. The conference had been initiated by the Canadian Westinghouse Company, of Hamilton, Ontario, in celebration of the Company having attained its jubilee manufacturing in Canada, and the conference members, numbering more than three hundred, were the guests of the Company. Church, Government, education, administration, science and industry were represented. The papers and their authors were as follows: "The Canadian People", Dr. B. K. Sandwell, of the *Financial Post*; "Canada's Natural Resources", M. W. Mackenzie, executive vice-president, Canadian Chemical and Cellulose Co., Ltd.; "The Challenge to Science", Dr. R. K. Stratford, scientific adviser, Imperial Oil, Ltd.; "The Contribution of Industry", D. W. Ambridge, president and general manager, Abitibi Power and Paper Co., Ltd.; "The Role of Government", M. Lamontagne, chairman of the Department of Economics, Laval University; "The Challenge to Education", Dr. N. A. M. Mackenzie, president of the University of British Columbia; "Cultural Evolution", Prof. H. Neatby, professor of history, University of Saskatchewan; "Canada in the World", Prof. D. G. Creighton, professor of history, University of Toronto; together with a paper representing a critical summary and assessment based on the papers just mentioned, which had been prepared by Prof. Denis Brogan, of the University of Cambridge, and which was presented at the dinner with which the conference was brought to a close. On the afternoon of November 12, the day before the proceedings of the conference opened, an honorary doctorate was conferred at a special degree congregation on Mr. H. H. Rogge, president of the Canadian Westinghouse Company, by the University of Laval. It is understood that the papers presented and the discussion on them will, in due course, be published in book form.

Geographical Association: Annual Conference

THE annual conference of the Geographical Association will be held in the London School of Economics, Houghton Street, London, W.C.2, during December 30, 1953–January 2, 1954. The meeting will commence with the presidential address, by Dr. O. J. R. Howarth, who will speak on "The Commonwealth in the Geography Syllabus". Besides a number of lectures, there will be three symposia on the following subjects: the place and use of Ordnance Survey maps in the primary school; specialization in sixth forms; and geography in further education. Excursions will be made to the Map Room of the British Museum, the Central Forecasting Office, Dunstable, the Darwin Museum at Down House, Downe, Kent, and to the Port of London Authority. On January 1 at 3 p.m. there will be a joint meeting with the Royal Geographical Society and the Institute of British Geographers at the Royal Geographical Society's House, London, S.W.7 (admission by special ticket only), at which Mr. T. D. Bourdillon and Mr. C. W. F. Noyce will give a lecture on "The Ascent of Everest, 1953, and its Significance". In conjunction with the conference the Association is holding its usual exhibition of books, maps and appliances (including visual aids) for the teaching of geography. Further information can be obtained from the honorary conference organizer, Dr. W. G. V. Balchin, Department of Geography, King's College, Strand, London, W.C.2.

Conference on Embryology and Experimental Morphology

A SCIENTIFIC conference associated with the annual meeting of the Editorial Board of the *Journal of Embryology and Experimental Morphology* will provide embryologists in Great Britain with an opportunity to discuss the latest work of many of their European colleagues. The meetings will take place during January 9–12 at University College, London, and papers will be read by M. Abercrombie, J. Brachet, A. Dalcq, E. Faure-Fremiet, S. Horstadius, F. E. Lehmann, J. Pasteels, Chr. P. Raven, S. A. Stefanelli, S. Toivonen, C. H. Waddington and Et. C. Wolff. On January 11 demonstrations of research material will be given by J. Brachet, A. M. Dalcq, S. M. Manton, P. B. Medawar, D. R. Newth, J. Pasteels, A. Stefanelli and C. H. Waddington. The meetings are open to all biologists, and details of them may be had from Dr. D. R. Newth, Department of Zoology, University College, London.

Lectures on Atomic Energy

THE Atomic Scientists' Association and the University of London Extra-Mural Department are arranging a course of six lectures on "Atomic Energy", to be held in the Beveridge Hall, Senate House, Malet Street, London, W.C.1, on successive Wednesdays at 7 p.m., commencing January 20, 1954. The titles of the lectures and the speakers will be as follows: atomic research at Harwell, by Sir John D. Cockcroft, director of the Atomic Energy Research Establishment, Harwell; atomic weapons, by Prof. O. R. Frisch, Jacksonian professor of natural philosophy, University of Cambridge; power from atomic energy, by Prof. F. E. Simon, professor of thermodynamics, University of Oxford; radiation hazards of atomic energy, by Dr. J. F. Loutit, director of the Radiological Research Unit, Harwell; medical uses of atomic energy, by Dr. E. E. Pochin, director of the Department of Clinical Research, University College Hospital, London; and atomic energy and moral issues, by Prof. Kathleen Lonsdale, professor of chemistry, University of London, and Sir George Thomson, master of Corpus Christi College, Cambridge. The fee for the lectures is 10*s.* for the complete course or 2*s.* a lecture. Tickets and further information can be obtained from Prof. J. Rotblat, Physics Department, Medical College, St. Bartholomew's Hospital, Charterhouse Square, London, E.C.1.

Harwell Isotope School: Courses during 1954

THE Isotope School at the Atomic Energy Research Establishment, Harwell, which teaches the techniques of using and handling radioactive materials to scientists, directors and industrial research workers, is holding five courses during 1954 on the following dates (the latest date of application is shown in brackets): Course 21, January 11–February 5 (December 12, 1953); Course 22, March 1–26 (February 1); Course 23, August 30–September 24 (August 2); Course 24, October 4–29 (September 6); Course 25, November 15–December 10 (October 18). The School building, which is equipped with the latest apparatus, is outside the security fence; lectures and instruction are given by members of the Harwell staff. Students pay a fee of £40 for the course, and living accommodation can be arranged in the neighbourhood at moderate charges. Applications should be sent to the Isotope School, A.E.R.E., Harwell, near Didcot, Berks.

Overseas Scholarships Scheme of the Federation of British Industries

DR. W. ABBOTT, formerly H.M. staff inspector of engineering at the Ministry of Education, has been appointed director of studies in connexion with the overseas scholarships scheme of the Federation of British Industries. Mr. W. V. Jenkins, who has been responsible for the operation of the scheme since its inception, remains as manager. The scholarships scheme now embraces Australia, Chile, Cuba, India, Iran, Pakistan, Peru and the Sudan, and is in process of being extended to other British territories and certain foreign countries, especially in the Middle East. The first two groups of scholars from Latin America, four from Peru and three from Cuba, have recently arrived in Britain and begun their training at engineering works in various parts of the country. Scholars from other Latin American republics are expected shortly. Three more Indian scholars have also begun training, making a total of twenty-six graduates who are receiving their training under the scheme. Six have already returned home after completing their training.

University of Birmingham

THE following appointments have recently been made in the University of Birmingham. Dr. J. A. H. Waterhouse, lecturer in human genetics, has been given the title of reader in medical statistics. Dr. P. L. Krohn has resigned his readership in endocrinology in order to accept a Nuffield Gerontological Research Fellowship, tenable in the Department of Anatomy; funds are also provided for the salaries of research assistants and the cost of equipment and materials. Dr. E. J. Hamley has been appointed a lecturer in physiology. The following have been appointed to fellowships in the University: P. Reasbeck, Imperial Chemical Industries, Ltd., Fellow in physics; Dr. F. M. Mohtadi, Imperial Chemical Industries, Ltd., Fellow in chemical engineering, R. T. Allsop and H. R. Thresh, research Fellows in industrial metallurgy; and Dr. M. A. A. Jorro, research Fellow in metallurgy.

Colonial Service: Recent Appointments

THE following appointments have recently been made in the Colonial Service: P. Devonald, agricultural officer, Northern Rhodesia; M.-H. D. F. Fyfe, P. R. Goldsworthy and C. E. Metcalfe, agricultural officers, Nigeria; C. Harkness and G. Jenkins, plant breeders (botanists), Nigeria; A. J. Pritchard, geneticist, Tanganyika; J. A. Whitehead, agricultural officer, Tanganyika; J. H. Bean and D. E. H. Rishworth, geologists, Federation of Malaya; H. J. C. Kirk, geologist, North Borneo; J. B. E. Williams, geologist, Jamaica; K. S. Hedger, veterinary officer, Kenya; F. Manolson, veterinary officer, British Honduras; A. O. Merry, veterinary officer, Sarawak; E. D. Wright, veterinary officer, Nigeria; T. R. Barnard, assistant conservator of forests, North Borneo; J. P. Dempster, entomologist, Cyprus; C. J. Hadley, assistant conservator of forests, British Solomon Islands Protectorate; D. C. Lyon, assistant conservator of forests, Uganda; N. Manley, meteorologist, Trinidad; R. J. Murray, petrologist, Geological Survey, Gold Coast; G. M. Newble, meteorologist, Nigeria; H. E. J. Wools, assistant conservator of forests, British Guiana.

Announcements

THE David Anderson-Berry Prize for 1953 of the Royal Society of Edinburgh has been awarded to Dr. John Read, British Empire Cancer Campaign, New Zealand Branch, of the Medical School, Dunedin, New Zealand, for fundamental work on the relation between oxygen tension and the effect of X-rays on tissues.

DR. A. S. CLARKE, at present lecturer in zoology in the University of Glasgow, has been appointed assistant keeper in the Department of Natural History in the Royal Scottish Museum.

THE title of reader in entomology, as applied to hygiene, in the University of London has been conferred on Dr. J. R. Busvine, in respect of the post held by him at the London School of Hygiene and Tropical Medicine, and the title of reader in psychology in the University has been conferred on Dr. Hildegard T. Himmelweit, in respect of the post held by her at the London School of Economics and Political Science.

MR. ALEXANDER PATON, a divisional lands officer in the Department of Agriculture for Scotland, has been appointed technical development officer in the Department in succession to Mr. A. R. Wannop, now director of the new Hill Farming Research Organization. Mr. Paton is a former student of the University of Glasgow and of the West of Scotland Agricultural College and, after a short academic career, joined the Department of Agriculture for Scotland in 1931. In 1945 he became a divisional lands officer, first in the western area and later in the east, and recently he has acted as chief technical officer to the Hill Lands Commission. He is to be succeeded by Mr. J. S. Gibson, at present senior lands officer in the Department, with headquarters at Dundee.

THE new Chemistry Building of the University of Sheffield will be opened by the Earl of Scarbrough on February 5. A special degree congregation will be held on this occasion, when the following honorary degrees will be conferred: *LL.D.*, Mr. T. A. McKenna, chairman and managing director, Staveley Coal and Iron Co., Ltd.; *D.Sc.*, Sir Cyril Hinshelwood, professor of physical chemistry in the University of Oxford, and Prof. C. K. Ingold, professor of chemistry, University College, University of London.

IN order to assist laboratory workers who wish to protect rabbits against myxomatosis, the Laboratory Animals Bureau of the Medical Research Council has prepared a memorandum dealing with the aetiology, pathology and epidemiology of the disease, and with vaccination, together with some references. Copies of the memorandum can be obtained from the Laboratory Animals Bureau, M.R.C. Laboratories, Holly Hill, Hampstead, London, N.W.3.

THE Lalor Foundation, through a grant to the Marine Biological Laboratory, Woods Hole, Massachusetts, is offering a limited number of post-doctoral fellowships in the fields of biochemistry, biophysics and physiology, designed primarily for young scientists desiring to work not less than two consecutive months during the summer on investigations for which the opportunities provided by the Marine Biological Laboratory are particularly appropriate. The stipend is intended to cover laboratory fees, travel, and living expenses at Woods Hole. Completed applications should be received by January 31, 1954. Application forms and further information can be obtained from the Director, Marine Biological Laboratory, Woods Hole, Mass.

A FELLOWSHIP and a number of scholarships for work on arctic or sub-arctic research are being offered jointly by McGill University and the Arctic Institute of North America, with the financial support of the Carnegie Corporation of New York. The fellowship, which is worth 4,000 dollars, is for a senior worker who has completed his or her studies in the field and requires a year's residence at a centre of learning in order to prepare the results or to work on related topics. The scholarships are tenable at McGill University, normally for one year, and are worth 1,000 dollars with 1,250 dollars expenses for a summer field expedition. They are designed for taking a subject that requires active field research probably, but not necessarily, in order to proceed to a doctorate. Further information regarding these awards can be obtained from the Secretary, Carnegie Arctic Program, Arctic Institute of North America, 3485 University Street, Montreal, P.Q. Applications must be sent in by January 1, 1954, except that scholarship candidates not intending to do field-work in the summer of 1954 need not apply until April 1, 1954.

ERRATUM. In the article on "Advances in Methods of Studying Clays" (see *Nature*, 172, 287; 1953), the statement on p. 288, col. 1, lines 14–13 from the bottom should read: "In the second paper Dr. Gordon and G. W. Harris described . . .".

INSTITUTE OF PERSONNEL MANAGEMENT

THE annual conference of the Institute of Personnel Management is one in which eminent speakers are given opportunities to suggest means whereby the good human relationships already prevailing in British industry are maintained and extended. This pattern, and its bearing on productivity, was followed at Harrogate during October 4–6, when some eight hundred personnel officers from a large number of industrial undertakings in Britain and Commonwealth countries assembled at the fortieth anniversary conference of the Institute.

The introductory address was given by the Earl of Verulam, managing director of Enfield Cables, Ltd., who drew upon experiences derived from visiting some sixty foreign countries during the past few years to show that British industry will only be able to capture export markets when there is quicker practical application of new ideas and patents and a much more radical approach to topics like packaging and advertising.

In a paper sparkling with wit and profound simplicity, Prof. M. Kendall discussed the application of statistical method to human problems.

First, he suggested that a statistical attitude could be a useful corrective to errors of the intuitive approach even on delicate matters involving personnel selection and management; secondly, that statistical laws could often provide a yard-stick even if they were only honoured in the breach instead of in the observance; and, thirdly, that some businesses and some situations are so complicated that only a statistical control of staff is possible, short of overloading the concern with personnel management to an unbearable extent. Thus, in the case of labour turnover, it seems the general rule that turnover is more rapid for women than for men, that there are enormous variations in the rate from one business to another, and that the younger age-groups are more mobile than the older ones.

From the statistics he obtains, the statistician is able to discern definite patterns of behaviour which are observed in other kinds of industrial behaviour such as accident proneness; from the evidence, some individuals would seem to be as liable to change their jobs frequently as others are liable to accidents. This suggests that it might be possible to find some single measure of turnover which would eliminate the effect of individual proneness and reveal the essential differences between firms, so that a manager who was worried about his turnover figures could compare himself with the average or with comparable businesses, and begin to locate the source of the trouble or discover whether the remedial measures were likely to have the right effect in the right age-groups.

Statistical method could also be applied to one of the most outstanding problems of industrial management, the question of relative wages. The political conception that all men should be paid alike has largely disappeared, while the old economic forces which used to determine relative earnings under a *laisser-faire* economy have also been largely removed. In their turn, these controls have not been replaced by others to determine the basis upon which the earnings of different categories of workers might be based. Here the problem of relative earnings might be set in a statistical framework which shows that wage patterns follow the Pareto law, which was originally devised to govern the distribution of incomes. Despite the social revolution of the past fifty years, the law seems to have a kind of stability which is proof against even large changes in economic structure. In determining a fair wage structure, the Pareto law offers a standard by which to work and a yardstick by which to judge of the success and probable stability of the settlement.

Other fields where the statistician might have contributions to make to business organization are the optimum size of a business and the problem of centralization versus decentralization, the speed of diffusion of new ideas in different media which is important both inside and outside the business, the effect of medical advances on pension schemes and age of retirement; and there is a whole field of problems in business strategy, such as how to design an air service, which is generating a new subject known as linear programming. Prof. Kendall also described the application of statistical techniques to time studies and the selection of personnel.

A former adviser to the Government on important financial matters and now a director of several companies operating in the Far East, Sir Andrew McFadyean, examined the wider aspects of finance and full employment in a free society leading to a high and progressively higher standard of living. During the past few years a condition of full employment has been maintained whereby, according to a Nuffield College definition, the number of unfilled jobs has not been appreciably below the number of unemployed persons, so that any unemployment has been due to the normal lag between a person losing one job and finding another.

This period of full employment was the natural result of the release of civilian demand which was pent up during the years of war, the huge back-log of orders arising from the inevitable failure to maintain and renew plant and equipment, and of a policy which combined with a policy of cheap money a distaste for disinflationary measures. The rate of interest is all-important, since a very low rate of interest makes overdrafts easy; and, with prices rising, people are quite content, and even prefer, to put their reserves into stocks, rather than keep them in money; as soon as there is the slightest recession this begins to cause difficulty. When money becomes dearer, the difficulty may become acute. It also means, when there are more jobs than men, that employers pay quite a lot to keep their employees at almost any price. That is one of the tendencies which conflicts with what ought to be a feature of full employment, namely, much greater mobility of labour. Easy money also encourages spending, which is concentrated on consumer goods and conflicts with the desirability that people should save for capital purposes.

Full employment, as defined by Beveridge, depends, first, on a higher degree of discipline among workers, and on the capacity of management to meet new problems. Secondly, it depends on the formulation of some collective wage policy which would prevent one body of workers seeking a sectional advantage at the expense of all the others.

The difficulties of the post-war period of full employment have suggested that its maintenance requires repeated periods of mild inflation to prevent prices from falling, to create an illusion of high profits, and to stimulate industrial producers to greater activity. But the open and avid pursuit of a policy of inflation to maintain full employment defeats its own ends. The possibility of saving will be diminished by constantly rising prices and the willingness to save will be weakened by the knowledge that money is likely to lose some of its purchasing power. This would lead to social instability of the gravest character. The maintenance of full employment depends on the ability to produce what the consumer wants at a price which he is able and willing to pay; it depends also on production at a profit. Machinery cannot be maintained, still less scrapped and replaced by new equipment, and the progress of invention and discovery cannot be maintained, unless a proportion of the profits earned are regularly set aside for these purposes. It is questionable whether the necessary provision for full employment is being made when a company pays well over half its profits to the Chancellor of the Exchequer by way of income tax and profits tax, and when the nominal profits on which it is taxed are, to an important extent, fortuitous because the amount which can be deducted from gross profits set off as depreciation takes no account of the real replacement cost.

The great mass of net income to-day is in the hands of people who have not been used to saving, largely because, in the past, they had no opportunity. It is to be hoped that thrift may be established among the rising generation of wage earners. There are, however, two dangers. A Welfare State does not encourage thrift, and unless full employment can be maintained without inflation and the rise in prices which inflation entails, it will be impossible to conceal that what is saved steadily decreases in value, and that, therefore, it would be better for people to consume more and save less. Full employment may actually be incompatible with that high standard of living which is to-day connoted by the term 'Welfare State'.

Nor must the industrialist produce at a profit what the consumer can and will buy; the consumer to be satisfied with a large part of the production is the foreign consumer. In selling abroad, British exporters are exposed to the fierce test of competition. In the ultimate analysis, workers, managers and investors are driven back to achieving not merely greater production but also greater productivity. Moreover, unless financial measures are taken to preserve the momentum of full employment, the country will, in due course, be faced with a percentage of unemployment which will represent many less jobs than seekers for work.

Sir Andrew stated that the maintenance of full employment, even in Britain, is a world problem and not a purely British one. It is primarily an American one. Unfortunately, if and when expenditure on arms is radically reduced, no American party, and therefore no American administration, dare aim at taking all the steps necessary to maintain a high level of industrial activity in the United States; it would involve a technique of control without detailed intervention.

To conclude the Conference, Sir John Woods, former Permanent Secretary to the Board of Trade and now a director of the English Electric Co., Ltd., discussed ways and means of convincing British people that the maintenance of existing standards of life depends upon their own efforts. Instead of the familiar slogan 'export or die', Sir John examined the role of imports in the British economy and suggested that the new slogan should be 'import or die'. Imports can now only be got from our own current labours. This, therefore, involves more production for export, and unless people were content with a good deal less for their own consumption, it means more total production. This larger total production has to be obtained at a time when means to buy the imports of materials for that production are lacking, and at a time when equipment—the actual capital equipment—is less than adequate because of what happened in the War.

Since the War there has been the greatest possible difficulty in obtaining imports. Throughout that period, import restrictions of one kind and another have been in force. Even that restricted volume of imports could not be obtained without assistance from overseas, and, for some time, credit from countries in the sterling area. In other words, the volume of our current foreign exchange earnings from exports has not been sufficient for the necessary, let alone the desired, volume of imports. Nor has there been at any time sufficient exchange reserves—particularly gold and dollar reserves—to tide us over for any period in which, for one reason or another (for example, a temporary falling-off in exports), our existing import bill could not be sustained out of current earnings. The gold and dollar reserves have been a barometer. There have been three crises since the War—in 1947, 1949 and 1951—and on each occasion the gold and dollar reserves drained away at an alarming rate.

The gold and dollar reserves are still not large enough to carry us over any period of recession which lasted for any length of time. In real purchasing power, the reserves are probably not worth more than a third to a half of what they were before the War, and the second cushion of the accumulated foreign investment does not now exist. If there should be an American recession of any length the prospects would be grave.

To-day there is some general awareness of the difficult and continuing national economic problem. Nevertheless, in spite of all that has been said and done on the subject of our national need for increased production and productivity, the basic truth has not been sufficiently absorbed. For example, it does not seem that the reports of the productivity teams have, in fact, been acted upon to any great extent. The argument has not gone deep enough into the community, and Sir John discussed reasons for this.

First of all, there is the essential difficulty of the subject. People really find it difficult to understand terms like inflation, deflation, exchange-rates, convertibility, tariffs and quotas, the terms of trade, and others. Moreover, these elements admit of different solutions.

Words like disequilibrium, balance of payments, the sterling balances, convertibility and GATT mean very little to the average person who is not forced to consider them as part of his occupation. Secondly, there has been too large an element of lecturing of the public—lecturing as opposed to discussion.

There is another class of difficulty which is more formidable. This is the fear of unemployment. The memories of 1931 are still very strong, and have bitten very deep into the consciousness of people in Britain. These fears may not be wholly out of date. Britain is immensely dependent on world trading conditions, and if other countries will not, or cannot, buy our goods, or will not, or cannot, buy the primary commodities of the sterling area countries, recession and unemployment in Britain cannot be prevented. Our best chance of averting the worst consequences of a possible slump is to increase our present strength, and our reserves of strength, by following the doctrine of increased production and productivity.

The more intractable difficulty is the 'group' interest. In trade and industry, there are two clearly marked *large* groups—management or employers on one hand, workers or trade unionists on the other. Each of these groups itself comprises many other economic groupings. There are often disagreements and rivalries, stresses and strains, between the various component parts of, as well as between, the two groups. It is noticeable, for example, how strongly the pattern of wage claims is influenced by a desire in one industry to maintain its relative position *vis-à-vis* other industries, as though the existing pattern must be right for all time.

Within the field of economic groupings, each individual will tend to concentrate his attention on the particular section, probably the nearest and smallest to which he belongs, and much less attention on other sections, even those that belong to the same general group. If, too, within each group (that is, management–labour) there are rivalries and dissents, it is the more likely that when the opposing sides meet, at whatever level, it will be in an atmosphere of antagonism or 'againstness'.

As a result there is a danger of opposing for opposing's sake, and of missing the opportunity to construct new ideas to meet new needs. If this view of the group interest is correct, society as a whole, which is the biggest group of all, will get relatively little attention or understanding. Yet it is now the supreme individual interest of everyone to look at the problem of the society as a whole, for now we are concerned with survival as a nation, and failure would bring disastrous economic consequences to all.

How is that understanding and recognition to be brought about? One way might be in small discussion groups of people in the same factory or shop. If anything of this kind were to be tried, it would have to be carefully prepared, and the people who led these discussions would have to be people of very high calibre. It would also have to be done with the complete goodwill of the management and of the union concerned.

The other main feature of the annual conference of the British Institute of Management is a series of sectional meetings at which topics of particular concern to personnel officers are considered. This year four such meetings were held, and were arranged on experimental lines in order to secure maximum 'audience participation'. The matters discussed were the use of wages as an incentive to higher production, the means of securing co-operative attitudes from workers, personnel management as a career and the improvement of selection methods for unskilled workers. The experiments, which copied techniques borrowed from the United States, were sufficiently successful to merit further trials.

T. H. HAWKINS

THE CRAFTSMAN IN THE ENGINEERING INDUSTRIES

A PRESIDENTIAL address delivered to one of the major professional institutions is normally devoted to the subject which has engaged the greater part of its author's career, and not unnaturally the study of man and men is therefore a frequent theme. In his presidential address on October 16 to the Institution of Mechanical Engineers, Mr. A. Roebuck turned his attention to the importance of the craftsman in industry, the necessity of the professional engineer recognizing his importance, and the necessity for the craftsman to be taught more of the scientific principles upon which his trade is based. With these sentiments no one can quarrel; but when Mr. Roebuck suggests that ". . . without the craftsman . . . the work of professional engineers and technicians would be of no avail, but, on the other hand, if the craftsman is left to himself he will produce an answer", an emphatic protest must be made. The double training of the professional engineer, so rightly insisted upon by the major institutions, makes it possible for him to learn rapidly any craft that he may need to master, while frequently enabling him to devise methods of manufacture which do not call for craftsmanship. The state of development of the mechanical engineering industry compared with that of the electrical industry should serve to underline the dangerous fallacy that is being propounded by Mr. Roebuck, since the former still depends primarily on the craftsman at the bench and the latter on the professionally trained designer.

It is fashionable to deplore the lack of skilled craftsmen and draughtsmen in engineering works to-day, and it seems a pity that Mr. Roebuck in his address did not analyse this very serious problem; it is primarily in the industries which are dependent on the professional engineer and the scientific worker that a major attack on the problem of training craftsmen thoroughly is being made, and that the best craft training schools now exist on a wide scale.

Some twenty years ago another president of the Institution of Mechanical Engineers, Sir Richard W. Allen, wrote a paper in which he directed attention to the very thorough training in craftsmanship given in the German-speaking engineering world, and suggested that it might profitably be introduced in Great Britain. In Britain a boy becomes a "craftsman" by serving a five-year apprenticeship; in Germany and Switzerland the boy has to pass a trade test at the age of eighteen in order to become a journeyman, and a further test at twenty-one in order to become a master. The examiners are skilled men appointed for the district, and the apprentice must produce detailed note-books showing sketches and descriptions, duly signed by his foreman, of every job that he has done. Many members of the teams that visited German industry at the end of the Second World War were struck by the pride taken by German works-managers and directors, more often than not graduate engineers themselves, in their training shops, which were to be found even in the smallest firms.

If, as Mr. Roebuck maintains and all will surely agree, the skilled craftsman in a works is all-important, why is he not treated as such and put on the staff? Admittedly the attitude of the trade unions has not been helpful when the idea has been raised; but every engineer must have been disturbed at some time or another by the privileges enjoyed by junior office-workers in comparison with those accorded to tried servants of the company "on the clock".

An analogous position is to-day to be found in most drawing offices. At the top are skilled mechanical designers, mostly in their late fifties or sixties; but where are their successors? The men who should be following them started as apprentices in the shops, took the first opportunity to get out of the shops into the drawing office, and then proceeded by dint of hard work to qualify as associate members of one of the Institutions; this opened the door to 'design', sales and all the other apparently more lucrative and socially more attractive avenues in the company. Until the importance and the difficulty of first-class mechanical design-work on the drawing board is recognized in terms of both salary and status, the situation can only continue to decline, while professional engineers and scientific workers become ever more frustrated at the lack of men able to translate their basic concepts into hardware without constant supervision.

The old methods of training craftsmen both in the shops and drawing office depended essentially on time. During the War the Ministry of Labour training centres, making use of the work of Sir Frederic Bartlett, showed that by modern methods of selection and training a degree of skill could be attained by men and women in times that make nonsense of the old conception of the five-year apprenticeship. One looks forward to the day when it will be possible to review a presidential address describing the success of a large firm in applying scientific methods to the selection and training of its men.

D. B. WELBOURN

FORECASTING WEATHER FROM SOLAR RADIATION

MORE than seventy years ago Dr. S. P. Langley began measurements of the solar radiation and its spectrum. By 1902 his results had led him to the belief that the so-called 'solar constant' was in fact a variable, and that its variations might be an important factor in terrestrial weather. In 1905 the research was taken up by C. G. Abbot, who has continued it ever since with single-minded devotion. In the second of the two papers here under consideration*, he sums up his conclusions, in an endeavour to persuade meteorologists to abandon their general scepticism or lack of interest, and at least to give him a fair hearing.

There are several reasons for this scepticism. Measurements of the solar constant have to be made through the atmosphere, and even on high mountains a proportion of it fails to reach the ground. In theory it is possible to estimate the loss by making a series of observations at different solar elevations, but in practice the complex structure of the upper atmosphere makes the results somewhat uncertain, and many meteorologists remain unconvinced that the observed variations are not, in reality, variations of atmospheric absorption. Some even regard the average computed value of the solar constant as too low by an amount much larger than the observed variations. Agreement between values obtained in widely different parts of the world has done something to meet this objection, though it is probable that many of the disturbing factors, in the higher layers, are world-wide in extent. But even granted that the solar constant does vary, the variations found by Dr. Abbot are so small—only one or two per cent—that their direct effect on surface temperatures would be barely perceptible. Dr. Abbot counters this by the argument that the terrestrial effects are indirect, associated with changes in the location of the sub-tropical anti-cyclones and prevailing storm-tracks, and the frequency of hurricanes, all of which affect temperature and rainfall.

There is, of course, no doubt that changes do occur on the surface of the sun, and that some of them are more or less periodic—the existence of the sunspot cycle and of solar faculæ is sufficient evidence—and it is reasonable to accept that, along with variations of other types of radiation, such as corpuscular, ultra-violet and radio wave-lengths, they give rise to variations of visible and infra-red solar radiation. But Abbot goes far beyond this by claiming that these variations are strictly periodic, and that they are all harmonics of the double sunspot cycle of 22¾ years. He enumerates at least twenty-three such harmonics, ranging from 2¼ months to 272 months. The amplitudes obtained are mostly microscopic, of the order of 0·1 per cent.

Such a complex array would require a rigid mathematical basis to justify its acceptance; but the method by which it is arrived at is crude and can scarcely be described as mathematical at all. From the description, it consists of plotting the data on a long curve, regarding it from a distance, and picking out the dominant periodicity by eye. This is then computed arithmetically and eliminated, the process being repeated until only non-periodic variations are left. Anyone who has worked with periodicities will realize the pitfalls of this graphical analysis, for the eye of faith only too readily sees regularities in the most irregular of curves. The process is bolstered up by dividing the material into sections; but to the critical eye the agreement between the different sections is not very good.

When we turn to the effect of these supposed variations of the solar constant on weather, the impression received is equally dubious. Dr. Abbot himself writes: "*it would be quite impossible for meteorologists to discover these regular periodicities in weather elements had they not first been found in solar variation*". The italics are his; but it is difficult to see how this argument helps his case. In support, he produces a number of curves illustrating various solar periodicities in the temperature of Washington and the precipitation of Albany, for various seasons and intervals, for high and low sunspot numbers. Some of the series seem chaotic, but some do show an appreciable resemblance, which is enhanced by introducing rather arbitrary shifts of the time scale.

However, one must be fair. No matter how crude Dr. Abbot's methods may appear to a statistician, he has the courage of his convictions. In the first paper he gives a closer study to the monthly temperatures at Washington. In the departures of 1854–1939 from monthly averages, he finds no fewer than twenty periodicities ranging from 4⅓ to 45½ months. These were used as the basis for 'predicting' the departures for 1940–51, which were not used in the calculations of the periodicities. The results have a correlation of 0·504 with the observed values. From about thirty independent values (the figures are smoothed over five months) this makes a real connexion fairly probable (if it has not been introduced by the 'adjustments' of scale), but is far from justifying the claim that it is "obvious and certain". A further, real, forecast is given on the same basis for 1952–59, and it is interesting to compare the forecast temperatures with the observed as far as they are available (the observed temperatures have been supplied by the Meteorological Office, Harrow). Both forecast (*F*) and observed (*O*) temperatures are smoothed over five months.

---

* Smithsonian Miscellaneous Collection. **122**, No. 1, Long-Range Effects of the Sun's Variation on the Temperature of Washington, D.C. (pp. 14; Pub. 4131), **122**, No. 4, Solar Radiation, a Leading Weather Element (pp. 35; Pub. 4135). Both by C. G. Abbot. (Washington, D.C.: Smithsonian Institution, 1953.)

		Jan.	Feb.	Mar.	April	May	June	
1952	*F*	39·1	40·4	47·8	56 9	66·2	72·6	°F
	O	42·0	44·6	49·2	56·4	64·4	71·2	°F
		July	Aug.	Sept.	Oct.	Nov.	Dec.	
	F	75·7	73·9	66·2	56·8	44 2	35 2	°F.
	O	73·6	72·0	66·2	57·8	50·6	46·2	°F.

		Jan.	Feb.	Mar.	April	May	June	July	
1953	*F*	35·3	35·9	43·1	54·2	63 7	72·4	78·9	°F
	O	43·6	45·2	51·4	58·2	65·8	71·4	74·2	°F.

Considering the extensive smoothing, while an error of less than 3° F. might be regarded as a good forecast, more than 3° F. would be poor, and more than 5° F. bad. The forecast temperatures are reasonably accurate for the first ten months of 1952 and for May and June 1953, but from November 1952 to March 1953 and July 1953 they fail badly. Twelve good against six bad forecasts suggest that, while there may be some basis for Dr. Abbot's predictions, it is far from sound, and certainly does not justify the issue of a forecast.

C. E. P. BROOKS

FEDERAL FOREST ADMINISTRATION IN MALAYA

ANNUAL REPORT FOR 1951

THE annual forest reports of the Federation of Malaya for 1949 and 1950 gave testimony to the remarkable progress being made by the Forest Department in spite of the Japanese occupation during the Second World War and the present-day troubles (see *Nature*, 167, 679 (1951), and 169, 700 (1952)). The report for 1951* by the director of forestry, Mr. J. P. Edwards, shows that the progress has been continued.

Further to this, however, the report is of historical interest in that, in an introduction on the history of the Malayan forests and their development, material of vital importance is recorded which has so often been lost in other countries in the past through failure of records. As early as 1883 a small department was set up in the Straits Settlement under the director of gardens. Four years later Mr. H. N. Ridley became director, and he carried out an extensive programme of reservation of valuable forests which would otherwise have been entirely destroyed during the 1910 rubber boom in Malacca; reservation of forests on the higher hills in Penang was also effected. Control of the forests was assumed by the land officers in 1895 and continued until 1901. The forests of the former Federated Malay States had also been in charge of the district land officer in Perak, Selangor and Negri Sembilan.

The introduction of an up-to-date forest conservancy resulted from a visit of a distinguished Indian forest officer, Mr. H. C. Hill (later inspector-general of forests in India), in 1900, who submitted a comprehensive report on forest administration in the Colony. This was followed by the appointment in October 1901 of Mr. A. M. Burn-Murdoch (from the Burma Forest Department) as the first chief forest officer, Federated Malay States and Straits Settlements. Burn-Murdoch laid the foundations of the Department as it is to-day. The Department has been fortunate in having had several first-class successors to carry on the work so effectually. Forest research was started with the appointment in 1918 of the late Dr. F. W. Foxworthy as forest research officer. Not only did Foxworthy place the branch in a strong position which has since been added to (including recently a new up-to-date laboratory for research on wood anatomy, mensuration and timber); but his work also became widely known in other parts of the world.

E. P. STEBBING

TERTIARY FLORAS

THE rich fossil flora of the well-known Middle Tertiary lake bed at Florissant, Colorado, some 8,500 ft. up in the Central Rocky Mountain regions, is notable for its very numerous species and for the excellent preservation of the plant impressions of twigs and leaves, with some fruits, seeds and flowers: there is also an abundant fauna, chiefly of insects. The general features of the flora are well known from earlier descriptions by Lesquereux, Cockerell, Knowlton and others. A recent monograph by Dr. MacGinitie*, in the finely produced series of the Carnegie Institution of Washington, gives a revised and extended account of the flora, with a full analysis of its relationships with other floras of the remarkable North American Tertiary series, and special interest is attached to the use of the Florissant plant population as a climatic indicator, and in dating the lake bed, the age of which has been uncertain.

A glance at the list of synonyms and changes of name indicates the wide extent of the taxonomic revision involved. From earlier accounts, some 258 species have been described;, but this revision reduces the number of well-established species to 114. Of these, 110 are species of seed plants (mostly trees and shrubs) representing 84 genera from 44 families, and 20 new species are included. The most abundant plant in the flora is *Fagopsis longifolia*, belonging to an extinct genus which so far as is known is peculiar to Florissant: this genus has previously been included in the Fagaceae, but is now referred by MacGinitie to the Betulaceae on the evidence of the attached "cones". Among other abundantly represented species are *Zelkova drymeja*, *Chamaecyparis linguaefolia*, *Typha lesquereuxi*, *Populus crassa*, *Sequoia affinis*, *Cercocarpus myricaefolius* and *Athyana haydenii*. Using the fossil species the relationships of which with modern species are reasonably clear, a comparison is made with living floras: and the picture of the Florissant flora which emerges is one of predominantly warm temperate facies. The living species most similar to the majority of the fossil species are found in floras of the south-western interior of North America, principally in the Texas–Mexican region; but there are also plants at Florissant the present-day affinities of which are with Chinese, Californian and South American species. For example, the fossil species *Lomatia lineata*, which is identified from both foliage and fruit, is closely similar to the living South American *L. ferruginea*, and provides reliable evidence for a former more northerly spread of the Proteaceæ, which to-day is characteristically a family of the southern hemisphere. The comparison between the fossil species and these living representatives forms the basis of a reconstruction of the environment: the wide range and large number of species used gives conviction to the conclusion that the climate was probably a warm temperate one with a pronounced dry season, and this has had independent corroboration from a study of the fossil Diptera of the lake beds, as well as from the ecological indications of the associated sediments. The age of the lake beds is also deduced from the flora and is established as early Oligocene, after comparison with the Colorado Green River flora of mid-Eocene age and the Oregon Bridge Creek flora of Oligo-Miocene age, the two North American Tertiary floras of this region which show the most significant similarities with the Florissant flora. Again, there has been corroboration of this from a study of the scanty vertebrate remains and from the lithology of the deposits. While many of the species differences between these floras are no doubt due to extinction and to migration, it is clear that there are at least some species in the Florissant flora which are derivative from Green River forms, and the resemblances may, indeed, be due to continuous floristic development in the same area; for example, this may well have been the case with the species of the Asiatic genus *Zelkova* in the floras.

---

* Report on Federal Forest Administration in the Federation of Malaya for the Year 1951. By J. P. Edwards. Pp. 67+4 plates. (Kuala Lumpur: Govt. Printer, 1952.) 2 Malay dollars or 4s. 8d.

* Carnegie Institution of Washington. Contributions to Paleontology. Fossil Plants of the Florissant Beds, Colorado. By Harry D. MacGinitie. Pp. iii+198+75 plates. (Publication No. 599.) (Washington, D.C.: Carnegie Institution of Washington, 1953.) Paper, 5.25 dollars; cloth, 5.75 dollars.

Though lacking any cuticular studies, which, indeed, may not be practicable with this material, such revision and analysis of a Tertiary flora bids fair to establish some of the history of the angiosperms, both of lineages and migrations, on a more secure basis, as well as offering useful indications of geological age and climate.

REGISTER OF RESEARCH IN THE SOCIAL SCIENCES

THE issue of the "Register of Research in the Social Sciences for 1952–3" (pp. 213; 1953; 25*s*.), published by the Cambridge University Press for the National Institute of Economic and Social Research, London, shows that the total amount of research of which particulars are given to the Institute is still increasing. This appears, however, to be due to the fact that the number of new entries each year greatly exceeds those which are removed from the "Register" because they are completed. During the preceding three years, the number of new entries has, in fact, fallen from 245 to 201, and although the number completed has risen from 121 to 140, the total number of entries has increased in the same period from 334 to 648.

This seems to show that research work in the social sciences tends to be a somewhat protracted process. It is obvious that most of the projects are being continued over longer periods than three years; but it remains to be seen how long it takes before the first substantial results are usually obtained from work of this kind.

Too much importance should not, however, be attached to these figures, or the conclusions based on them. The scope of the "Register" and of the projects listed in it is very wide indeed; the range is from "Soviet Law and Government" and "The Pure Science of Politics", which may be deemed to provide a lifetime of work for several scholars, to "What is an Office Manager?" and "A Forecast of Effects of Economies in London Telephone Directory Services", which are at least much more limited undertakings. The compilation of the "Register" is an exceedingly difficult task; but it will not be possible to use it for any more fundamental purpose than a mere list of work in progress unless the editors decide to prune the entries more rigorously.

DISTRIBUTION OF THE BRUSH POSSUM IN TASMANIA

By Dr. ERIC R. GUILER

Department of Zoology, University of Tasmania

THE brush possum *Trichosurus vulpecula* (Kerr) is found in most parts of Tasmania. In some localities, however, the distribution of the species is partly restricted by the absence of trees. One of the most interesting features of the biology of this species is the distribution of the black and grey colour phases. Pearson[1] found that there was no climatological reason for the apparently well-defined distribution of the black variety; but a recent examination of new material shows an ecological correlation of the distribution of the two colour phases.

The brush possum forms an important part of the Tasmanian fur industry, and skins collected during a short open season are liable to royalty. The royalties received are entered on a return by an officer, usually a policeman, acting on behalf of the Animals and Birds Protection Board. The statements are sent to police headquarters at Hobart. I am indebted to the Police Department for allowing me to peruse the returns, which show the number of water-rat, kangaroo, wallaby, ringtail and brush possum skins taken and the localities from which they came. The two colour phases of the animal are sufficiently important economically to warrant classification on the return as 'black possum' and 'grey possum'. Hence it is possible to obtain, assuming the form to be correctly entered, a reasonably accurate picture of the distribution of the two colour phases. Owing to the destruction of all records prior to 1947, those for the year 1949 are the only ones available. The years 1947, 1948 and 1950–51 were closed seasons. The total number of possum pelts taken is given in Table 1.

Owing to the lack of satisfactory evidence of place of capture, the figures, on which the distribution

Table 1

Number of *Trichosurus* pelts taken during the 1949 open season in Tasmania and the number included in the present survey:

	Black	Grey	Total
No. branded	22,792	68,023	90,815
No. included in present survey	11,988	23,250	35,238

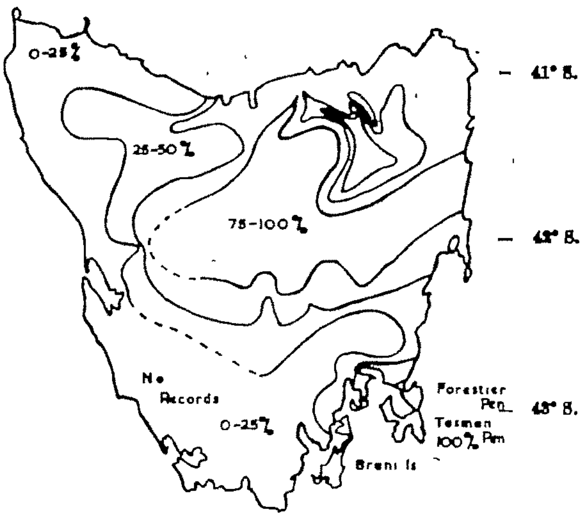

Fig. 1. Distribution of the black and grey colour phases of *Trichosurus* in Tasmania. The figures give percentage of greys

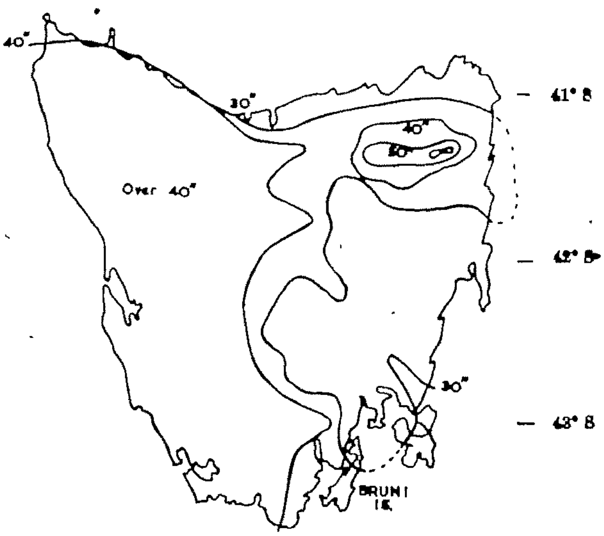

Fig. 2. Rainfall in Tasmania based on records supplied by the Hobart Weather Bureau

curves are based, do not include about two-thirds of the total number of skins taken. However, they do include just over 50 per cent of the black skins.

In the final analysis of the returns, the percentage of grey skins for 215 stations was obtained. These percentages were plotted on a map and the distribution curve drawn. Because in some cases the sample was not sufficiently large to be of significance, a few records had to be discarded.

In the present communication I employ the term 'possum' to distinguish the Australian phalangers from the American didelphids. In this I am following Troughton[4] and others.

Fig. 1 shows the distribution of the two colour phases of *Trichosurus* in Tasmania. The treatment used is the same as that employed by Pearson (*loc. cit.*), namely, the percentage of greys is shown. Individual stations are not indicated but will be listed in a later paper.

The most significant change from Pearson's map is the presence of an area of low percentage of greys in the north-east corner of the State. Whereas Pearson used figures from some eight stations in this area, I have utilized the results from fifty places, so giving a more detailed picture. The distribution can be seen immediately to be mainly correlated with rainfall (Fig. 2), although the presence of high land without any stands of large trees may modify the curve. In the regions of high rainfall, for example, the north-west, west coast and south-west of the State, there is a high percentage of black possums, whereas in areas of low rainfall there is a high percentage of greys. Thus the east coast and midlands are rich in the grey phase. The central highlands have a very high percentage of greys (98 per cent at Great Lake) and this region extends far out towards the west coast. The observations for this extension are very meagre, being based on a sample of fourteen from only one station, hence the curve is dotted. The 40-in. isohyet crosses the north coast in a position which is significantly close to that of the 25 per cent grey curve. Similarly, allowing for an inaccuracy resulting from the method of obtaining distribution results, the area showing a high percentage of blacks, in the north-east, also corresponds to the 40-in. isohyet.

There are no black possums on King or Flinders Islands in Bass Straits. This is in accordance with Pearson's findings, though there is a small percentage of blacks on Hunters Island, adjoining the north-west tip of Tasmania.

In the southern part of the island, the high percentage of blacks in the region extending almost across to the east coast does not correspond to the rainfall isohyet, nor to the distribution of forest areas. This distribution is based on percentages from only five stations, so there may be an experimental error, though the samples from four of these stations are each of more than twenty skins.

Pearson found a low percentage of black possums from the Forestier Peninsula as well as the Tasman Peninsula (83 per cent grey). Analysis of the 1949 figures shows that 22 per cent of the population on the Forestier Peninsula are black, but I have no figures from the Tasman Peninsula. From the known rainfall, the figure from the Forestier Peninsula is in accordance with expectations.

The only part of the Tasman Peninsula which experiences 40 in. of rainfall is a small area around Port Arthur, and in this area there is virtually no standing timber, heath being the dominant ecological feature. In a 40-in. rainfall belt black possums might be expected; but in this case local vegetational factors do not favour their occurrence. There is a similar 40-in. area near Adventure Bay on Bruni Island, but I have no observations from that region. In the Allonah area of Bruni Island there appears to be 100 per cent grey, which is again what one might expect. The following general correlation is shown in Table 2.

Table 2

Percentage of colour phase of *Trichosurus* correlated with rainfall

Rainfall	Percentage possum phase
> 40 in.	> 75 per cent black
30–40 in.	50–75 per cent black or grey
< 30 in.	50–100 per cent grey

The relative humidity on the east coast and the Midlands–Central Plateau region is lower than on the north-west coast, west coast and the south-west. The maximum humidity is 95 per cent near the west coast (Weather Bureau, 1936).

Pearson considered that an invasion of *Trichosurus* took place, the point of entry being from the north-east corner, and that the black form became more abundant the farther the species moved away from its point of entry. Huxley[3] follows Pearson's arguments. On superficial evidence this may be possible, but I consider it more likely that the black mutant arose in regions of Tasmania where the rainfall and humidity were found suitable, and that it has become dominant over such areas. This is more in accordance with the accepted general principle that in regions of high humidity the dark races are more frequent. Under such a hypothesis, the barrier effected by Eaglehawk Neck, which was described by both Pearson and Huxley as preventing the spread of the black form to Tasman Peninsula, does not need to be considered, because the low rainfall of the Peninsula would not be a suitable habitat for the black phase.

It is significant that not only does the distribution pattern of the black possum correlate with climatic and vegetational factors, but so, also, does the pattern in the black rabbit[4]. *Trichosurus* has been introduced into New Zealand; but it has not been established for a sufficient length of time for a rainfall distribution pattern to become apparent (Kean, personal communication). AMINOLÆVULINIC ACID AND PORPHYRIN BIOSYNTHESIS

By DR. A. NEUBERGER, F.R.S., and J. J. SCOTT
National Institute for Medical Research, Mill Hill, London, N.W.7

IT has been known for some time that the protoporphyrin molecule is synthesized in the red blood cell by condensation of eight molecules of glycine with eight molecules of a compound derivable from α-oxoglutarate[1-3]. Shemin and Kumin[4] showed by means of isotopically labelled acetate and succinate that such a compound appeared to be an asymmetric derivative of succinate. On the basis of the isotope data then available, a mechanism of porphyrin synthesis was suggested[4] in 1950 by which the first pyrrolic compound formed in the biosynthesis was a dicarboxylic pyrrole (V) with two free α-positions. It was then assumed that the methene carbon atoms (derivable from glycine) were added later; in this way the predominance in Nature of porphyrins related to aetioporphyrin III and the occurrence of smaller quantities of series I porphyrins could be explained.

With this theory in mind, we set out in 1952 to synthesize a number of compounds formally derivable from glycine condensed with one or two molecules of succinic acid, which might be intermediate in the conversion. We hoped that, by labelling the compounds isotopically, we would be able to demonstrate a higher degree of incorporation into hæmin than that obtainable with labelled free glycine or succinate.

A carboxyl group of succinic acid may be condensed with glycine either by N-succinylation or by an α-C-succinylation analogous to the Dakin–West reaction. In the first case succinamido-acetic acid (I), and in the second case α-amino-β-oxo adipic acid (II) would be formed. The latter compound would be expected to decarboxylate readily to form δ-aminolævulinic acid (III). By addition of a second molecule of succinic acid, succinamido-acetic acid or δ-aminolævulinic acid could be converted to δ-succinamidolævulinic acid (IV) by a similar process. This compound, by an oxidative self-condensation, might then form a pyrrole of the type shown below (V). A third possibility was that two molecules of δ-aminolævulinic acid could undergo a Knorr-type condensation to give a pyrrole, bearing in addition an aminomethyl α-substituent (VI).

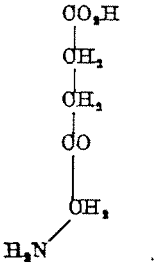
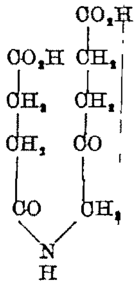
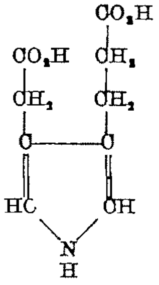
II



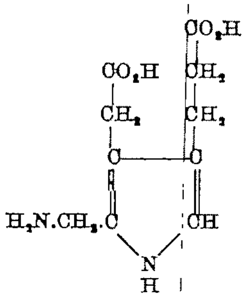
III



IV



V



VI

In order to test these possibilities the following compounds were prepared. (1) [α-^{14}C] *succinamido-acetic acid* was prepared by condensation of ethyl [α-^{14}C] bromo-acetate with succinimide in the presence of potassium carbonate in dimethylformamide. This was followed by saponification with acid and hydrolysis of the imide by treatment with baryta. (2) *δ-Succinamido-lævulinic acid* was prepared by reaction of methyl succinyl chloride with diazomethane, and condensation of the resulting chloro-ketone with succinimide. Careful hydrolysis gave the required compound. (3) *δ-Aminolævulinic acid hydrochloride* was obtained from δ-succinamido-lævulinic acid or from methyl [^{15}N] δ-phthalimidolævulinate by acid hydrolysis. A third synthesis consisted of a condensation of phthalyl glycyl chloride with diethyl methyl ethanetricarboxylate, followed by ester exchange with benzyl alcohol and catalytic reductive de-esterification according to Bowman[5], and subsequent hydrolysis of the resulting δ-phthalimido-lævulinic acid. The latter method was designed as a basis for individual labelling of all five carbon atoms. The properties of δ-aminolævulinic acid hydrochloride were identical with those described by Corwin[6].

Experiments in rats and rabbits showed that $[\alpha\text{-}^{14}C]$ succinimidoacetic acid produced no significant labelling in the hæm of hæmoglobin isolated five days after intraperitoneal injection, nor was this compound converted to glycine at a significant rate. Tests kindly carried out by Dr. J. Lascelles, of the Department of Biochemistry, Oxford, showed that neither succinamido-acetic acid nor δ-succinamido-lævulinic acid stimulated porphyrin synthesis in intact cells of *Rhodopseudomonas spheroides*[7]; this could have been due to impermeability of the cell membrane. More conclusive negative evidence was obtained in tests of the two compounds by Dr. J. E. Falk and Dr. E. Dresel, of the Department of Chemical Pathology, University College Hospital Medical School, London, in a lysed fowl red cell system[8]. It seemed, therefore, that the first two possibilities, involving either succinamido-acetic or succinamido-lævulinic acid, had been excluded. On administration to rats of $[^{15}N]$ δ-aminolævulinic acid hydrochloride, either by feeding or intraperitoneally, there was some labelling in the hæmin; but it was about five times lower than that resulting from an equivalent dose of $[^{15}N]$ glycine. Experiments in which benzoate was injected at the same time showed that no extensive transformation of aminolævulinic acid to glycine takes place in the rat. However, tests in the lysed red cell system, kindly carried out by Dr. Falk and Dr. Dresel, showed that aminolævulinic acid is equivalent to porphobilinogen (see below) in producing a net increase in the levels of uro-, copro- and protoporphyrin. These results suggest that the first pyrrolic compound formed is, in fact, compound VI. In May[9] and September[10] this year a structure for porphobilinogen was advanced, identical with VI. Evidence for the participation of porphobilinogen in porphyrin synthesis was obtained recently by Falk, Dresel and Rimington[11], who found that it was converted in 60 per cent yield to a mixture of porphyrins when incubated with lysed bird red cells.

Before the biological work with these labelled compounds was completed, a paper by Shemin and Russell[12] appeared, in which it was shown conclusively by the use of both $[^{15}N]$- and $[\delta\text{-}^{14}C]$-labelled aminolævulinic acid that the incorporation of this compound into hæmin in a duck red cell system is forty-four times greater than that of similarly labelled glycine. The data presented here, particularly the observations of Falk and Dresel, confirm their findings.

Experiments to test the stability of δ-aminolævulinic acid hydrochloride in aqueous solution indicate that a condensation takes place, at a rate which increases with rise in *p*H, to form a compound which is not porphobilinogen, but which is believed to be a derivative of dihydropyrazine, by analogy with known reactions of α-amino ketones. It is presumably either for this reason, or owing to metabolic instability, that the utilization of aminolævulinic acid for porphyrin synthesis is so small when the compound is administered to the whole animal.

We wish to thank Dr. J. E. Falk, Dr. E. Dresel and Dr. J. Lascelles for their co-operation in the testing of these compounds, also Dr. N. Berlin, who assisted in the final stages of this work, a full account of which will appear in subsequent papers.

BIOLOGICAL SYSTEMS AND THE PRINCIPLE OF MINIMUM ENTROPY PRODUCTION*

By Dr. D. C. SPANNER

Department of Plant Physiology, Imperial College of Science and Technology, London

THE idea of a steady state is one which makes a fairly immediate appeal to our intuition, though it is not always clearly distinguished from the equilibrium state. In both, the observable characteristics of a system show no change with time; but while in the steady state there are one or more macroscopic processes continuously proceeding, any processes occurring in the equilibrium state are postulated rather than observed. The number of distinct observable processes accompanying the steady state is spoken of as its 'order', and with this convention equilibrium becomes merely the steady state of zero order. It is a well-known fact that a system left to itself reaches equilibrium when its entropy has increased to the highest possible value; and this consideration raises the question as to whether there is not some comparable 'variation principle' which could be established for the steady state. On the basis of the first and second laws of thermodynamics alone it proved impossible to find such a generalization; but an advance was made in 1931 when the Norwegian physicist Onsager introduced into thermodynamics the principle of microscopic reversibility, which simply states that if at a given instant the motions of all the particles of an isolated system could be exactly reversed, the system would retrace its former history.

Principle of Minimum Entropy Production

This led, in the hands of Prigogine[1] and others, to the realization that the characteristic property of a system which always tends to a minimum and which reaches it in the steady state is the entropy production; that is to say, the rate at which entropy is being created by irreversible processes within the system. If the system is quite unfettered it proceeds, of course, to equilibrium, when the entropy production is actually zero; but steady states arise when in one or more ways the system is constrained away from equilibrium. In these circumstances it readjusts itself under the influence of the constraints to just such an extent as to reduce its entropy production to the smallest possible value. Thus, if a uniform solution in a rectangular vessel has opposite faces maintained at different temperatures, a partial separation of the constituents occurs (Soret effect). In accordance with the principle under discussion the concentration gradients which arise develop to the extent necessary to reduce the heat flow through the system to a minimum. If they are prevented from developing, say by thin partitions, the heat flow will remain at a higher value.

---

* The substance of an address delivered at the Sheffield meeting of the Society for Experimental Biology, 1953.

Of course, the fixed constraints applied to the system need not take the form of temperature differences. Gradients of concentration or chemical activity may be imposed, giving rise to transport processes as in the above example. Further, scalar 'forces' like chemical affinity may be involved, and these will produce continuous chemical reactions. Whatever the nature of the imposed 'forces', however, the system will readjust itself in any way open to it, and this readjustment will go only so far as suffices to reduce the total of the internal dissipative processes to their lowest possible value. How low this value will be it is impossible for thermodynamics to say. Sometimes the entropy production may fall scarcely at all; at others, it may become almost zero.

Biological Systems

Since biological systems are, broadly speaking, isothermal systems, it is more convenient in their case to speak of free energy rather than of entropy. Thus the steady state becomes a state of minimum dissipation of free energy. Put into this form, it appears that biological systems will show a tendency to conserve their free energy, a tendency already implied in ordinary physical laws. On the gross scale, as Prigogine and Wiame[2] have pointed out, this is rather clearly the case, for living organisms show a progressive decline during their lifetime in their rate of metabolism per unit mass. An obvious difficulty, however, lies in the fact that the curve of free energy dissipation does not fall consistently throughout the lifetime; even adult organisms show periodic outbursts of activity during which their energy dissipation must sharply increase. This, however, may be reconciled with the principle in at least two possible ways: sometimes the free energy dissipation may rise owing to a change in the external constraints, as when day succeeds night, or a meal is ingested; and sometimes a quiescent condition may be merely a *metastable* steady state. This latter may be the case when, without environmental stimulus, an animal becomes stirred to activity. In both cases the system may be supposed to move to a new steady state, determined in the first case by the new external constraints; and in the second, by the consideration that it is a more stable condition under the old constraints.

Structural Features of the Cell

Turning to the individual cell, it is possible to interpret some of its structural features as illustrations of the principle. Consider, for example, the perhaps universal occurrence of a fatty membrane of extreme delicacy around the cell, and probably around many of its internal structures as well. In an open system such as the cell, diffusion of metabolites inwards and outwards across its boundary will be a very essential part of its metabolic processes. Such diffusion, representing a dissipation of energy, is very materially hindered by the presence of the membrane, and it thus becomes possible to conceive of lipoid molecules arranging themselves in the most restrictive position much as a sponge does in an emptying bath. Similar considerations may, possibly, govern the structural localization of enzymes in the cell.

Biochemical Considerations

With regard to biochemical considerations it would seem that the principle has some very interesting implications. The enzyme phosphatase added to an aqueous solution of glucose phosphate will hydrolyse it to glucose and phosphoric acid, the standard free energy of the reaction being about 3,000 calories. If, however, a suitable alcohol be first added the phosphatase will catalyse the production of alkyl phosphate rather than phosphoric acid, in spite of the fact that the standard free energy change is considerably less, perhaps about 1,000 calories. Since the dissipation of free energy is the underlying principle regulating the direction of its vital processes, it is not at once apparent why the cell should choose a reaction dissipating a smaller amount of free energy when a reaction dissipating a larger amount is available to it. It would seem possible that this is an example of the minimum entropy principle, and that what actually happens in the above case is that after a short initial period of hydrolysis the system readjusts itself so that as far as possible the transphosphorylation of the alcohol is favoured at the expense of the production of acid. If this is so, then it can be seen that in a general way ordinary physical principles will lead to such an organization of the biochemical life of the cell that the pattern of change will be made up of small free energy steps, no doubt a most important factor in its energy economy. Such a pattern of organization has often been noted.

In this connexion one may see a new significance in the use, by the cell, of highly specific enzymes. By canalizing biochemical reactions into what are, in effect, narrow channels, the cell may create the possibility of the state of minimum dissipation being, in fact, a state of very low dissipation. This state of affairs is analogous to the use by the cell of a lipoid membrane of pronounced specific permeability to seal its boundaries.

Periodic Changes in the Environment

One interesting general consequence of the principle is revealed by the response of organisms to rapidly interrupted stimuli. Once a constraint has been applied, a system begins to adjust itself to the condition of minimum dissipation. This, however, requires time for its attainment. If the constraint or 'stimulus' is removed and reapplied at sufficiently short intervals it will have a greater effect per unit time of its application than if it acted steadily, since the system will never be allowed to reach its most conservative condition. Such a behaviour is shown, for example, in flashing-light experiments on photosynthesis, or in the enhanced rate of growth of roots rotated in a klinostat.

Terminology of Enzyme Formation

It has been recognized for many years that in micro-organisms the formation of a large variety of enzymes can be specifically induced by exposing cells to compounds which are substrates for the enzymes in question. Recently, the same phenomenon has been demonstrated in a mammal[1], and it will probably prove to be a general property of biological systems. Since a change of this sort can occur against a constant genetic background, it must be distinguished from a change in enzymatic constitution that is primarily mutational. In order to distinguish between these two phenomena, microbiologists have for many years referred to the former type of enzymic variation as 'enzyme (or enzymatic) adaptation'. The term was, perhaps, an unfortunate choice[2,3] since the word 'adaptation' has an old and well-established biological meaning. In biological parlance, 'adaptation' denotes the modifications of either structure or function which increase fitness; mechanism is unspecified, and in fact both phenotypic and genotypic changes are included thereunder. Logically, therefore, 'enzymatic adaptation' should denote a modification of enzymatic constitution which increases fitness, irrespective of whether it involves genotypic or phenotypic change, and microbiologists have in fact often used it in this broader sense[4,5].

The use of the term 'enzymatic adaptation' to describe the direct induction of enzyme formation is open to objection for a second reason: enzyme formation can be specifically induced under conditions which preclude function of the enzyme so formed[3,6], a process which might be expected to have a negative effect (if any) on the fitness of the organism concerned.

It might prove unpractical to abandon the use of the term 'enzyme adaptation' altogether at this stage; but we should like to suggest that, in suitable cases where it is possible to be more precise as to the nature of the change underlying the increase in enzymic activity, a more accurate and significant terminology be employed. We therefore propose the following terms and designations; previously used terms are placed in parenthesis. A relative increase in the rate of synthesis of a specific apo-enzyme resulting from exposure to a chemical substance is an 'enzyme induction' (enzyme adaptation). Any substance thus inducing enzyme synthesis is an enzyme 'inducer'. An enzyme-forming system which can be so activated by an exogenous inducer is 'inducible', and the enzyme so formed is 'induced' (adaptive). Although many compounds can act both as inducer and substrate, the terms are not equivalent. Certain substrates for induced enzymes are not inducers, while some inducers cannot function as substrates of the enzymes the formation of which they elicit[3].

Many enzymes are formed in considerable amounts in the absence of an exogenous inducer. Such enzyme formation is 'constitutive' (constitutive). The amount of a constitutively formed enzyme can frequently be increased by specific induction, and it is also possible to obtain mutants in which synthesis of a particular enzyme is wholly constitutive (that is, not increased by any known inducer), from a parental type in which formation of the same enzyme is largely inducible[7,8]. Thus 'constitutivity' and 'inducibility' are properties of enzyme-forming systems, not of enzymes *per se*, and can be used as significant expressions only in a biological frame of reference, not in a chemical one. It should be stressed that the notions of constitutivity and inducibility are relative, not absolute; in any given biological system, a certain fraction of a particular enzyme-forming capacity may be constitutive, the remaining fraction inducible. For the sake of convenience, one may wish to refer to 'an induced enzyme' or to 'a constitutive enzyme'; but it should always be kept in mind that these are shorthand expressions for 'an enzyme the formation of which is largely or entirely inducible (or constitutive) in the particular organism concerned'.

The exposure of an organism to a single inducer which is also a substrate may result in the induction of a sequence of enzymes, since the metabolism of the primary, exogenous inducer gives rise to the formation of a succession of intermediary metabolites each of which in turn serves as an inducer for the enzyme which converts it into the next member of the metabolic chain. This phenomenon is termed 'sequential induction' (simultaneous or successive adaptation).

Nomenclature of *cyclo*Hexane Bonds

It was shown originally by X-ray and electron diffraction, and has been confirmed by other physical and by chemical means, that the most stable and permanent form of the *cyclo*hexane ring is that particular strainless form which is sometimes likened to a chair or a staircase. Geometrically, its chief feature is a six-fold alternating axis of symmetry. Its twelve extracyclic bonds fall into two classes[1]: six lie parallel to the axis, while six extend radially outward at angles of ± 109·5° to the axis. The stereochemical properties of substituents bound by these two classes of bond are so different that a need has been felt for verbal and symbolic means of distinguishing the classes.

The first suggestion[1] to this end designated the six parallel bonds as 'ε' and the others as 'κ'. However, although these symbols have been considerably used, heir origins in the Greek language, and particularly heir allocation between two classes of bond, have been found difficult to remember. A more obvious description was given[3] when the six parallel bonds were called 'polar' and the others 'equatorial' by analogy with the geographical terms. This nomenclature has had a wide use, but is unsatisfactory in that it employs the word 'polar' for a stereochemical concept, thereby tending to confuse discussions which have to take account of the electropolar nature side by side with the stereochemical character of *cyclo*hexane substituents.

The purpose of this communication is to suggest a simple change which avoids these difficulties. It is that the six bonds parallel to the main *cyclo*hexane axis should be called 'axial'[4] (and symbolized '*a*'), while the other six retain the name 'equatorial' (and become symbolized '*e*'). (The term 'axial' was suggested to us by Prof. C. K. Ingold, University College, London.) The private discussions we have had with friends and colleagues lead us to hope that this suggestion may find favour.

Determination of Dry Mass, Thickness, Solid and Water Concentration in Living Cells

IN previous communications it has been shown that the measurement of phase change by interference microscopy can be used for determining the dry mass of living cells[1], and the measurement of refractive index enables the concentration of solids and water to be calculated[2]. The combination of these techniques gives a method of measuring the thickness and hence the volume of living cells.

The principle of the method is to measure by interference microscopy the phase changes produced by an object when immersed successively in two media of different refractive indices. Let μ be the refractive index of the object, and t its thickness.

Let φ_1, φ_2 be the phase changes measured when the object is immersed in media of refractive index μ_1, μ_2, respectively. Then

$$\varphi_1 = (\mu - \mu_1)\,t\,; \qquad \varphi_2 = (\mu - \mu_2)\,t.$$

$$\text{Hence } \mu = \frac{\mu_2\varphi_1 - \mu_1\varphi_2}{\varphi_1 - \varphi_2} \text{ and } t = \frac{\varphi_1 - \varphi_2}{\mu_2 - \mu_1}.$$

These two measurements thus suffice to determine both the refractive index and the thickness of a homogeneous object.

In the case of living cells, we can write[1,2]:

$$\mu = \mu_s + \alpha C,$$

where μ_s is the refractive index of the intracellular fluid (effectively a dilute salt solution with a refractive index very close to that of water), α is the mean refractive increment of the cell solids, which can be taken as 0·0018, and C is the concentration of cell solids expressed as grams per 100 ml. If the cell is immersed in two different concentrations, C_1, C_2, of a suitable protein medium[3], we can write $\mu_1 = \mu_s + \alpha C_1$ and $\mu_2 = \mu_s + \alpha C_2$.

$$\text{Hence we obtain } C = \frac{C_2\varphi_1 - C_1\varphi_2}{\varphi_1 - \varphi_2} \text{ and } t = \frac{\varphi_1 - \varphi_2}{\alpha(C_2 - C_1)}.$$

In practice, the method is greatly simplified by carrying out the first measurement of phase change (φ_1) in a saline medium. In this case $C_1 = 0$, so that:

$$C = \frac{C_2\varphi_1}{\varphi - \varphi_2} \quad \text{and } t = \frac{\varphi_1 - \varphi_2}{\alpha C_2} = \frac{\varphi_1}{\alpha C}.$$

The experimental procedure is thus to measure the phase change first with the cell mounted in a saline medium, then to run in a dilute protein solution under the coverslip and take the new measurement. Not only does this method give more information than either straightforward interference microscopy or refractometry alone, but also it has the important advantages of not requiring an accurate refractive match and of allowing the use of much less concentrated protein solutions than is needed in ordinary refractometry.

Typical results obtained for different regions of the cytoplasm of human oral epithelial cells are given in Table 1. Values for dry mass per unit area in grams per square micron, thickness in microns, and concentration of solids in grams per 100 ml. have been calculated. The concentration of water as a percentage of total wet weight is given with sufficient accuracy by $100 - C$. Monochromatic green mercury light (λ 546 mμ) was used for the measurements.

Table 1

C_2 (per cent)	$\varphi_1°$	$\varphi_2°$	Dry mass (gm./μ^2)	C (per cent)	Concentration of water (per cent)	Thickness (μ)
8	17·3	7·1	$1·44 \times 10^{-13}$	13·4	86·6	1·07
12	32	10·5	$2·67 \times 10^{-13}$	17·4	82·6	1·50
6	4·5	8·0	$0·38 \times 10^{-13}$	18·0	82·0	0·21
6	11·0	6·5	$0·93 \times 10^{-13}$	14·7	85·3	0·64

It will be seen that there is a considerable range of variation of thickness in these cells, though they are all very flat. On the other hand, the concentration of solids lies within the range previously reported[3] and is much more constant. Refractive index and solid concentration are much more fundamental quantities than the phase change or dry mass, which depend on local variations in thickness in different parts of the same cell. A knowledge of the distribution of dry mass by itself is therefore of very limited value. The determination of solid concentration either as described here or previously[3] is virtually essential. In homogeneous regions of the cell the volume can be found by integrating the product of the projected surface area and thickness. As will be discussed elsewhere, however, serious errors may arise in the case of very heterogeneous regions, and only approximate calculations can be made in such cases.

I wish to acknowledge the help received as Johnston, Lawrence and Moseley Research Fellow of the Royal Society. This work was carried out with interference microscopes kindly lent by Messrs. Charles Baker and Mr. J. Dyson.

Origin of the Pituitary Body of Chordates

My earlier investigations on the neural gland of tunicates may perhaps throw some light on the origin of the pituitary body in vertebrates. I have adduced evidence[1-4] that the neural gland (plus ciliated pit) of tunicates is the homologue of the vertebrate pituitary body. The mouth of the ciliated pit, then, is the homologue of the opening of Rathke's pouch, and as such does not enter into the structure of the pituitary proper. The stage in the development of the tetrapod pituitary at which Rathke's pouch is open is thus a 'recapitulation' of a phylogenetic step, still extant in ascidians.

Now what is known of the function of the pituitary in ascidians? I have shown that it is a chemoreceptor for detecting the presence of gametes of its own species in ingested water[2]; and it is probable that it may also act as a sense organ (in *Salpa* at least) for assaying the relative abundance of particles (food particles) in the ingested water[4]. Can it be that the pituitary is primitively a sense organ? This is the hypothesis which best fits the data. The only proved function of the pituitary in ascidians is that of chemoreception, and the ascidians are more primitive than any other chordate whose pituitary has been investigated; moreover, no other chemoreceptor is known in ascidians. The pituitary seems, in fact, to be the organ of olfaction in these forms. It has often been postulated that the pituitary shares with the nose proper an olfactory function in the cyclostomes; and Prof. R. Dohrn informs me that recently workers in his laboratory have shown this to be so in *Torpedo*. It has been replaced, however, by the 'nose' for this function in the higher chordates. Why has such a replacement taken place?

It seems most likely that the change from a benthic to a nektonic way of life has necessitated the development of a faster-acting olfactory organ than the pituitary body, in which the passage of information to the brain is chemical[5]. The new, fast-acting olfactory organ, of course, passes its information by nerves. It may be, indeed, that the new olfactory organ develops by innervation of part of the pituitary: the association of pituitary and nervous olfactory organ in the cyclostomes may perhaps suggest this. However this is, the pituitary proper, having lost its olfactory function, now presumably remains because its incretory products, once just of use for conveying information to the brain, have meanwhile become important for other purposes. For example, the gonadotropins of the pituitary, which in ascidians convey information of the presence of gametes to the brain, have in the vertebrates become essential to the gonads for their development: the site of action of the hormone has changed from the brain to the gonad. The reflex chain of the ascidians, deduced from the experiments described in an earlier paper[2], has been short-circuited to some extent, cutting out the neural arm of the reflex arc, so that both arm are now hormonal. The organ, the original function of which has become obsolete in higher chordates remains because its incretory products have become essential to the body. This seems to be yet one more example of the rule that endocrine organs originally possessed some other function. Thus the thyroid i first a feeding organ, the endostyle, and when thi method of feeding becomes obsolete in the evolutionary ascent the endostyle has to remain as a purely endocrine organ, since an incretory produc has become essential to the body; the pineal is firs an eye; the gonads are reproductive organs before they are endocrine glands; the first function of the pancreas seems to be to secrete digestive enzymes. In every one of these endocrine glands, including the pituitary body, the endocrine function seems to be secondary. The first function of the pituitary would appear to be one of chemoreception.

Premature Oviposition in the Hen

It has been reported recently[1] that after various operations on the albumen-secreting region of the hen's oviduct, oviposition ceased almost entirely. This failure to lay was taken as evidence of a failure to ovulate and was attributed to inhibition at the pituitary gland by direct nervous stimulation from the oviduct.

During similar experiments, reported in this communication, it was noticed that if a loop of suture silk was placed in the shell gland in the manner described by Huston and Nalbandov[1], the production of normal hard-shelled eggs was replaced by the production of soft-shelled eggs in more than hal the birds operated upon. In these birds ovulation continued at nearly the same rate as before the operation; but the yolk could not be retained in the oviduct long enough for egg formation to be completed. About half the resulting soft-shelled eggs had membranes and the rest were of yolk and albumen only.

Table 1 shows the number of normal and abnorma eggs produced by eight of the fourteen experimenta birds for up to forty days after the operation; the remaining six birds and six controls continued laying normally at an average level of 70 per cent.

Table 1

Hen No.	Control period		Days after the operation							
	10 days		1–10		11–20		21–30		31–40	
	H	*S*	*H*	*S*	*H*	*S*	*H*	*S*	*H*	*S*
A	7	0	0	6	0	6	0	6	0	3
B	8	0	0	0	0	5	0	6	0	7
C	7	0	1	2	0	4	1	5	–	–
D	7	0	2	3	0	3	0	4	0	2
E	4	0	1	4	0	4	0	6	0	4
F	6	0	1	5	0	7	0	5	0	2
G	5	0	0	2	0	6	0	5	0	5
H	9	0	4	3	2	5	0	7	0	5

H = No. of hard-shelled eggs; *S* = No. of soft-shelled eggs.

These experiments are continuing and will be reported in detail later.

Thermal Contraction of Collagen and its Dissolution with Elastase

The structure and chemical characterization of elastic tissue by means of elastolysis and electron microscopy have been studied by Hall, Reed and Tunbridge[1], and by Lansing, Rosenthal, Alex and Dempsey[2]. The results of both laboratories agree in showing the complex nature of collagen-free elastin originating either from aorta or ligamentum nuchæ. In the elastic tissue the existence of a cement material —matrix—is suggested, of which the physical and chemical properties are similar to the fibrils imbedded in it. Recently, Schwarz and Dettmer[3], working with fresh aorta imbedded in cremolan (*Dünnschnitte*), found that during dissolution of elastin fibres by elastase, only the matrix called *Kittsubstanz* is dissolved, while fibrillæ remain intact and can be examined in the electron microscope. The elementary fibrillæ of the elastic fibres are identical with the collagen fibrils and also are periodically cross-striated. The discrepancy between the results of Hall *et al.*[1] and of Lansing *et al.*[2], on one hand, and of Schwarz and Dettmer[3], on the other, could be explained by my observation[4] that if fibres of collagen or purified collagen tissues are contracted by heat they can be dissolved by elastase. In order to obtain purified elastin the tissue must be boiled; the same procedure was employed by Stein and Miller, who boiled the ligamentum nuchæ in water for many days to remove collagen. Lansing *et al.*[2] described the preparation of pure elastin by boiling the tissues with 0·1 *N* sodium hydroxide for 45 min. at 98°. In their experiments, the amorphous matrix as well as the fibrillæ imbedded in it were dissolved during elastolysis, whereas in the experiments of Schwarz and Dettmer[3]—without heat denaturation—elastase produced only the dissolution of the *Kittsubstanz*.

The collagen can be dissolved by elastase if it is kept in water of 70° for 5–10 min., or in 2 per cent acetic acid at 60° for 5 min. Partridge[5] has shown that from dried cartilage powder after a short heat treatment with water at 60–70° a soluble mucoid may be extracted. The temperature required to liberate mucoid is reduced in the presence of calcium chloride, alkalis and formamide, and the conditions necessary to secure extraction in good yield are generally those which give rise to thermal contraction of collagen. Using Achilles tendon of cattle in my experiments, I succeeded in showing that during thermal contraction in water 5–6 per cent of the dry weight of collagen can be extracted. The extracted substance contains 6–8 per cent of polysaccharide, determined by Rimington's method[6], which is 25–30 per cent of the polysaccharide contents of the collagen. The transformation of collagen to an elastolytically soluble substance at lower temperature does not take place with 10 per cent calcium chloride or formamide; but it occurs in presence of 2 per cent phosphotungstic acid. Heat-denaturated collagen fibre, as well as phenol-treated collagen fibre, is rubber-like, showing elastic properties.

After thermal contraction, collagen loses its swelling capacity and is solubilized by elastase ten times faster than elastin itself. The substance of elastolytically dissolved collagen—called collagenolysate—is in respect of protein precipitation and dialysis similar to elastolysate derived from elastin. During dissolution the dicarboxylic amino-acids—aspartic and glutamic acids—of the collagen molecule are liberated in all probability from their amide bonds; thus in the collagenolysate using Willstätter's method, 1·1–1·2 mol. COOH/gm. collagen is found.

Both collagenolysate and elastolysate show a strong reducing action for which their polysaccharide content (1·2–1·8 per cent) cannot be responsible. This reducing capacity is revealed in the consumption of bromine or iodine, in showing positive reaction with Schiff's reagent after precipitation with 5 per cent phosphotungstic acid, and also in giving—without alkali treatment—red coloration with the Ehrlich reagent (*p*-dimethyl-amino-benzaldehyde) characteristic of pyrrole derivatives. These reactions misled us in our previous work[7], suggesting the presence of a greater quantity of carbohydrate (10–12 per cent) resembling glucosamine in the elastolysate.

In respect of amino-acid content, collagen differs from elastin in that it contains four to five times more dicarboxylic amino-acids. Probably the collagen fibrils are surrounded with the mucopolysaccharide-like envelope bound by the dicarboxylic acids; this prevents the elastase from attacking the appropriate group of molecules and exercising its digesting effect. If the mucopolysaccharide is removed by heat denaturation, the elastase dissolves collagen, which means that in collagen as well as in elastin the same structural elements are present upon which elastase acts specifically. In studying the elastolysis of heat-denaturated collagen obtained from rat's tail by means of the polarization microscope, it was shown that in agreement with Partridge's[5] results the contraction of collagen fibre is followed by its relaxation, depending on the heat and the salt concentration of the medium. Elastolysis ensues only in cases in which the fibres are already relaxed, and the first effect of elastase is to segregate the collagen fibre into fibrils parallel to its long axis like a broom. Then the fibres gradually lose their double refraction and fall to pieces. All these experiments seem to support my former view that the mechanism of elastase action consists of depolymerization of the protein molecule and transformation of the rod-shaped molecules into globular proteins. Experiments (unpublished) show that following the depolymerization process induced by elastase, a component arises which gives a mean molecular weight of 10,000–20,000. After inactivation of the enzyme, the breaking down continues and gives rise to products of a mean molecular weight of about 2,000.

A paper containing the detailed results of the experiments will be published in the *Acta Phys. Hung.*

THE observation of Dr. Banga that thermally contracted tendon collagen is dissolved under the action of elastase is obviously of great importance. There is considerable evidence that elastin preparations from aorta and from ox ligament, even after the presumed removal of collagen, do not present single substrates to the action of elastase[1]. In the course of a search for a purer substrate for elastase, we have also observed the dissolution of thermally contracted collagen both from Achilles tendon and from rat tail tendon. In addition we have found that elastase, acting at pH 8·7, causes the dissolution of the water-insoluble protein in bovine crystalline lens and of the lens capsule. The dissolution of lens capsule is particularly interesting, since the material shows some similarity in amino-acid composition to collagen, its X-ray diffraction pattern is like that of a partially oriented collagen, it contains much polysaccharide and has a definite marked shrinkage temperature between 60° and 70° [2]. We have thus shown that elastase will attack a collagenous material even when it has not been thermally contracted.

The complex structure of aorta and the close association of collagen and elastin fibres in this material makes it difficult for us to accept Dr. Banga's interpretation of the work of Schwarz and Dettmer[3]. With reference to their observations that the elastin fibrils are not dissolved under the action of elastase and are similar to collagen fibres in certain respects, we would point out that the particular set of conditions they employ, namely, incubation for ten hours at 37°, and pH 7, are not optimum for the action of elastase[4], and, moreover, they do not seem to have taken any special steps to remove collagen. The possibility pointed out by Dr. Banga, however, that the fibrillar structure of elastin may be altered in some way during the heat treatment employed for the removal of associated proteins is of fundamental importance, and one which must be constantly borne in mind.

'Multiple Dipping' Procedures in Paper Chromatography: a Specific Test for Hydroxy-proline

MUCH industry has been devoted in recent years to methods for locating the position of components separated on paper chromatograms, and claims have been made for many reagents of greater or less specificity. We wish to report our experiences in locating compounds on paper chromatograms by the successive application of several reagents with different specificities.

We have used mainly the better-known amino-acid and amine reagents, and find that several of them can be used one over the other if applied in an appropriate order. The use of Pauly reagent to confirm the identity of histidine after location with ninhydrin was advocated by Dent[1], and the use of two superimposed reagents, usually with the second applied to selected areas of the chromatogram only, has been mentioned by others[2]. Application t selected areas only is to be avoided if possible, sinc this is likely to miss the presence of other interestin reactors, as well as ending with a blotched chromatogram. We have used only the 'dipping' technique for application of the reagents used; and we obtai a very uniform background even after four reagent have been superimposed.

Ninhydrin, isatin and Ehrlich reagents are prepare and used in the manner already reported[3]. Our di reagent for the Sakaguchi reaction is a 0·1 per cen solution of 8-hydroxy-quinoline (oxine)[4] in acetone after drying in air, the paper is then dipped int a solution of 0·2 ml. bromine in 100 ml. $N/2$ sodiu hydroxide; arginine and other guanidines giv brilliant orange-red areas, fading slowly. The modifie diazo reagent formed from amyl nitrite and *p*-anisidin in ethanol[5] gives excellent results as a dip reagen for histidine and other iminazoles, but poor result with tyrosine. The nitroso-β-naphthol/nitric aci reagent of Acher[3,6], specific for tyrosine and certai of its derivatives, can be applied as acetone solutions

After applying one reagent, the chromatogram i heated or left for full colour development to proceed Spots and colours are then marked with lead pencil the next reagent applied to the whole chromatogram and so on. We term this a 'multiple dipping procedure.

Maximum information is given by sequences such as: ninhydrin or isatin, followed by Ehrlich reagent, followed by Sakaguchi reagent or diazo reagent. Ninhydrin can be applied over isatin. With the notable exception of hydroxy-proline (see below), the colours given by amino-acids with ninhydrin and/or isatin are rapidly 'rubbed out' by the strongly acidic Ehrlich reagent, which must therefore be applied after these two. It can, however, be followed by Sakaguchi reagent, or by the diazo reagent if $2N$ sodium hydroxide is used as dip solution for the coupling reaction. The nitroso-β-naphthol reagent is applicable after ninhydrin or isatin, but its sensitivity is considerably diminished. Other sequences of these reagents are incompatible or of little value.

This multiple dipping technique is useful for confirming, by specific reagents, the nature and position of components first located by a general reagent; for revealing the composite nature of a single spot; and for revealing two or more sets of components which do not each respond to the same general reagent (for example, urinary indolic compounds in the presence of amino-acids). A single one-way chromatogram treated with four separate and specific reagents can often give more information than a two-way chromatogram, with consequent saving of time and labour. We are at present utilizing the technique in the photometric scanning of chromatographic strips, the application of the various reagents yielding records which are directly comparable.

In general, the usual colour responses and sensitivities of amino-acids to the reagents mentioned are almost unaltered by previous treatment. One important exception constitutes a highly sensitive and specific test for ***hydroxy-proline***. After heating with isatin, the duck-egg blue colour due to hydroxy-proline is replaced by an intense purplish-red (cerise) colour within a few seconds of applying Ehrlich reagent over it. The effect is not seen when either acid or dimethylamino-benzaldehyde is applied alone. This colour test will detect hydroxy-proline at a concentration on paper chromatograms of 0·1 μgm./sq. cm.—considerably beyond the sensitivity of the simple isatin or ninhydrin reactions. It is ntirely specific for hydroxy-proline among more han a hundred and twenty amino-acids, amines and heterocyclic acids tested.

We suggest that when new location reagents are xamined, the extent to which they may be used in he ways outlined here should be investigated.

Effect of Surface Films on the Evaporation of Water

BY a variety of laboratory experiments, it has been demonstrated that the presence upon a water surface of a suitable monolayer or duplex film may diminish considerably the rate of evaporation[1-3]. That significant retardation of evaporation is not obtained under natural conditions is indicated by the lack of application of the techniques on a larger scale.

It has been stated[4] that the spreading of monolayers does not provide a practicable technique for restricting natural evaporation, because the resistance to transport of vapour provided by the film usually is small compared with the resistance offered by the non-turbulent layer of air above the water surface. It should be noted, however, that the alternative procedure of spreading thick duplex films provides no actual improvement. Fluid duplex films revert to an equilibrium state comprising a monolayer in equilibrium with lenses of oil[4], and in this form offer less resistance to the passage of water vapour than do monolayers of long-chain alcohols. Rigid duplex films are fractured readily by wind and dust.

In the present work, the intrinsic resistances of several monolayers and duplex films have been determined between 20° C. and 60° C., using a technique similar to that adopted by Langmuir and Schaefer[2]. The C_{16}- and C_{18}-aliphatic alcohols provided the least permeable monolayers of those examined, the maximum rate of evaporation through aged films being about six hundred times less than that determined for a clear water surface[1,5] at 25° C. It has been ascertained that monolayers of these substances are affected but slightly by wind and dust.

Except for two periods of a few hours duration, the spreading of monolayers did not reduce significantly the natural rate of evaporation during intervals of the 1952–53 Melbourne summer. On both these occasions, strong desiccating winds were experienced late on dull afternoons. During periods of the 1953 Melbourne winter an average reduction of 25 per cent has been obtained. Marked deviations about this mean value have been observed from day to day, depending on the weather. Simulation in the laboratory of various meteorological conditions produces a parallel variation in the efficiency of monolayers.

The explanation lies in the heat exchange between water and its surroundings. The restriction of evaporation leads to an increase in surface temperature, and accordingly to a compensating increase in the rate of evaporation. Under normal summer conditions, the compensating effect is sufficient to destroy the potential efficacy of a film. In cloudy weather the amount of long-wave radiation reaching the water surface is reduced, and both the surface temperatures and the significance of the compensating effect are decreased also. Accordingly, evaporation is retarded to an extent depending on such conditions. Strong winds also are helpful. It has been both calculated and observed that the absolute rate of evaporation from a film-covered surface decreases as the wind velocity increases, provided the surface receives a flux of radiant energy corresponding to that available near noon on cloudless summer days.

It is apparent that the spreading of surface films cannot significantly reduce the natural rate of evaporation during summer unless some method of restricting the absorption of (particularly long-wave) radiation is provided also. Appropriate investigations are in progress.

Analytical Separation of the Methyl Esters of the C_{12}–C_{22} Fatty Acids by Vapour-Phase Chromatography

James and Martin[1] separated the fatty acids up to lauric acid by passage through a column of kieselguhr and silicone DC.550/stearic acid at 137° C., and measured each fraction automatically by alkali titration.

Mr. N. H. Ray (Imperial Chemical Industries, Ltd., Alkali Division, Winnington) has applied the method to a variety of the lower-boiling alcohols, esters, ketones and hydrocarbons, using dinonyl phthalate (on 'Celite 545') as static liquid phase, and using catharometers and a high-speed recorder for detecting and measuring each component (private communication).

We have developed the technique of vapour-phase chromatography so that separation and measurement of the C_{12}–C_{22} fatty acid esters is now possible, at 230° C. The chromatographic column consists of a vertical spiral 1 in. in diameter with twelve turns (pitch ½ in.), so that the overall length of the column is about 3 ft.; this is packed with the dry mixture of 'Celite' (Johns Manville Co., Ltd.) and Dow Corning High Vacuum Silicone Grease (equal parts, previously mixed by grinding). At the entrance to, and the exit from, the column are attached two platinum-wire catharometers which are connected in a Wheatstone bridge arrangement so that the difference in resistance can be recorded by a Cambridge high-speed recorder. The column and catharometers are wound with asbestos tape so as to form a single unit, which is then placed in an iron cylinder, wound and lagged so that temperatures up to 300° C. (by adjustment of a 'Variac') can be attained. The

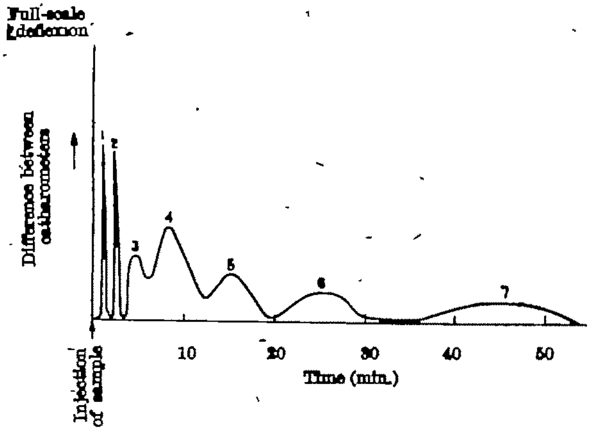

Fig. 1. Separation of methyl esters of C_{12} to C_{22} fatty acids: (1) naphthalene; (2) methyl laurate; (3) methyl myristate; (4) methyl palmitate; (5) methyl stearate; (6) methyl arachidate; (7) methyl behenate

sample (about 0·02 ml.) is introduced from a hypodermic syringe, the needle of which is pushed through a rubber cap at the top of the column; a vacuum pump gives 2 cm. mercury pressure in the exit catharometer, and about 40 cm. mercury in the inlet catharometer, which is fed with nitrogen (8 ml./min.) from a ballast reservoir and gas cylinder.

Under these conditions, the methyl esters of lauric, myristic, palmitic, stearic, arachidic and behenic acids are well separated, the first- and last-named reaching their peaks on the record in 2·5 min. and 45 min. respectively (see Fig. 1). In order to avoid exact measurement of the volume of sample put on to the column, we add previously to the bulk of the sample a known amount of naphthalene, which gives a very sharp band with the peak at 1·0 min.; measurement of the ratios of the peak heights of each ester to naphthalene (the 'internal standard'), and reference to calibration curves gives the amount of each ester on the column, expressed as percentage in the original sample. Oleic acid is not separated from stearic acid, and allowance must be made for this in subsequent calculations (that is, 'apparent stearic acid' figure is corrected according to the iodine value of the original sample). Results of single tests are reproducible to about ± 1 unit at the 10 per cent level, and ± 2–3 units at the 50 per cent level.

This chromatographic method is more rapid and reliable than the ester-fractionation method[2]. One sample examined by the latter method gave a considerable residue (28 per cent), which according to saponification value appeared to be almost pure methyl behenate; chromatography of the original sample showed the presence of large amounts of methyl arachidate (previously 'missed' in the ester-fractionation analysis), in addition to the expected myristate, palmitate and stearate, but only a small amount of methyl behenate was present. Chromatography of the residue from the ester-fractionation test showed that it was largely a complex mixture of unknown components, with only small amounts of the C_{14}–C_{22} fatty acid esters; evidently considerable decomposition had occurred during the lengthy distillation stage.

Small amounts of individual esters can be detected and measured in alleged 'pure' samples by increasing the load on the column; thus a sample (0·05 ml.) of methyl palmitate of melting point 29·5–30·0° C. (lit. 29° C.) contained 2·5 per cent of methyl myristate and 2·5 per cent of methyl stearate.

Each test takes about 40 min. to 'run' and, c course, the column is used repeatedly withou re-packing between tests. The method is applicabl to samples of the C_{12}–C_{22} fatty acids, after esterification on a 10-gm. scale by the method of ref. 2.

Lauryl, myristyl and cetyl alcohols are also easil separated under these conditions; we propose t investigate the separation of the methyl esters c oleic, linoleic and linolenic acids, and of the components of technical oleyl alcohol.

A detailed account of the investigation on the fatt acid esters and alcohols will be published elsewher

A Simple Chromatographic Method for the Determination of the C_{10}–C_{20} Saturated Straight-Chain Fatty Acids

In 1951, we described a semimicro chromatographi method for the separation and determination of the C_4–C_{10} volatile fatty acids[1]. In that publication description was given of the preparation of a silic gel which proved to be highly suitable for thi separation. In that method, which is based on th principle of Ramsey and Patterson[2], the fatty acid up to C_{10} are separated on a column of silicic acid using methanol as the immobile solvent, *iso*octan as the mobile solvent and bromocresol green as the indicator. Since this method is quick and simpl and never fails to give excellent results, we hav tried to work out an identical method for the determination of the higher saturated fatty acid C_{10}–C_{20}.

Our experiments showed that it is possible t separate these higher acids on the same column use for the C_4–C_{10}-separation; but a very long colum is necessary. Moreover, the higher fatty acids prove to be too weak to give a distinct colour change wit bromocresol green, which changes colour betwee *p*H 3·8 and 5·4. We therefore tried indicator changing at higher *p*H intervals. Bromothymol blue *p*H interval 6·0–7·6, proved to be adequate. On column tinted with bromothymol blue the colou change with these higher acids is very sensitive even amounts of about 0·1 mgm. of each acid giv yellow bands, which are clearly visible.

With the use of bromothymol blue a second ver important advantage was obtained. In preparin a tinted column, enough ammonia must be added t obtain the intermediate colour of the added indicator Using bromothymol blue, about twenty times as muc ammonia is required as in the case for bromocreso green. This relatively large amount of ammoni probably causes salt formation with the acid travelling through and consequently the partitio coefficients are considerably altered. With ou specially prepared silica-gel[1], tinted with bromothymo blue, neutralized with methanolic ammonia solution saturated with methanol and using *iso*octane (sat rated with a distinct excess of 95 per cent methanol) s the mobile phase, a column length of about 9 cm. sufficient to obtain a quick and quantitative eparation of the straight-chain even-numbered aturated fatty acids from C$_{10}$ to C$_{20}$. Recoveries of ingle acids and of the acids in mixtures were between 5 per cent and 105 per cent. Even mixtures conaining no more than about 0·5 mgm. of each acid ould be analysed with the same accuracy. Our xperiments indicate that the range of usefulness can e extended to C$_{22}$ and perhaps to C$_{24}$ acids.

As compared to the reversed-phase chromatography of Boldingh[3] and to the silica method of Ramsey and Patterson[4], our method has the advantage that the position of each acid is visible on he column, that each acid needs only one titration nd that the analysis is quick and simple.

A full description of the method will be given lsewhere.

The ^{54}Fe(n,p)^{54}Mn Reaction

Alper and du Preez[1], working in this laboratory, have reported the production in an atomic pile of manganese-54 from iron-54; but two later studies of pile-irradiated iron[2,3] have not shown the presence of manganese. To clarify the position, we have had the following samples irradiated in the Harwell pile: (1) one 1 gm. sample of sulphur; (2) two samples (10–13 mgm.) of iron enriched in iron-54 and wrapped in cadmium foil 20–30 mils thick; (3) two samples (3 gm. each) of spectroscopically pure iron also shielded with cadmium; (4) two samples of iron (1 gm. each) with no cadmium shielding.

The manganese-54 was separated from the irradiated iron samples in the following way. After dissolving in hydrochloric acid, the iron was oxidized to the ferric form and the acid concentration adjusted to 6·5 *M*. A carrier quantity of manganese was added, and this solution was extracted with ether to remove the bulk of the iron. After evaporation to dryness, manganese was reprecipitated six times, as the dioxide, by potassium bromate oxidation from a 0·25 *M* solution of sulphuric acid[4] to which carrier quantities of iron and cobalt had been added. The precipitation was repeated on the combined filtrates until the residual activity became effectively constant. This activity was due to permanganate formation, the full loss amounting to only 0·6 per cent of the total manganese activity. Activities in the manganese fractions, corrected for decay since removal from the pile, are given in Table 1.

Table 1

Sample	Mass of iron (gm.)	Percentage iron-54	Measured activity (microcuries)	Activity per gm. iron-54 (microcuries)
(2 *a*) Enriched cadmium	0·0130	70·63	0·943	103
(2 *b*) shielded	0·0100	71·39	0·787	110
(3 *a*) Natural iron cadmium	3·006	5·84[5]	15·0	85·5
(3 *b*) shielded	2·448	5·84	12·5	87·5
(4 *a*) Natural iron	0·989	5·84	5·22	90·6
(4 *b*) unshielded	0·978	5·84	4·91	86·6

Internal agreement is satisfactory, and the differences between the three sets can be explained by self-shielding in the massive iron samples. These results conclusively establish that the activity is produced by fast neutrons on iron-54. We have also obtained a half-life of 324 ± 11 days, and a gamma-ray energy of 825 ± 20 keV. for the separated activity. These agree satisfactorily with the accepted values for manganese-54 of 310 ± 20 days[6] and 835 ± 15 keV.[7].

Fast and thermal neutrons were present in approximately equal numbers, the flux of each being $(1 \pm 0{\cdot}1) \times 10^{11}$ cm.$^{-2}$ sec.$^{-1}$. The samples were irradiated for 120 hr. per week for three weeks. The cross-section for the production of manganese-54 calculated from these figures is 11×10^{-27} cm.^{2}. This is the order of magnitude to be expected for a reaction of this type produced by pile neutrons. From the phosphorus activity produced in the sulphur sample, we get the reasonable ratio of 14 : 1 for the cross-sections of the ^{32}S(n,p)^{32}P and ^{54}Fe(n,p)^{54}Mn reactions.

Our thanks are due to Mr. J. D. Louw, who determined the isotopic abundance of iron-54 in the enriched samples, to Mr. J. K. Basson for the determination of the gamma-ray energy, and to the Analytical Section of the National Chemical Research Laboratory, for chemical analyses.

Interstitial Atoms in the Layer Structure ZnMn$_3$O$_7$3H$_2$O (Chalcophanite)

CHALCOPHANITE crystallizes in the triclinic system, space group $P\bar{1}$, with $a = 7{\cdot}54$, $b = 7{\cdot}54$, $c = 8{\cdot}22$ A., $\alpha = 117{\cdot}2°$, $\beta = 90°$, $\gamma = 120°$. The crystal structure was determined by Fourier methods of X-ray analysis on a specimen from the U.S. National Museum, Smithsonian Institution.

The structure of this compound consists of sheets of water molecules interleaved between double layers of oxygen atoms co-ordinated to manganese ions. Six out of seven of the octahedral sites between the oxygen sheets are occupied by Mn^{4+} ions, the vacant site at the origin forming a trigonal planar grouping. A similar arrangement of vacant sites is found in

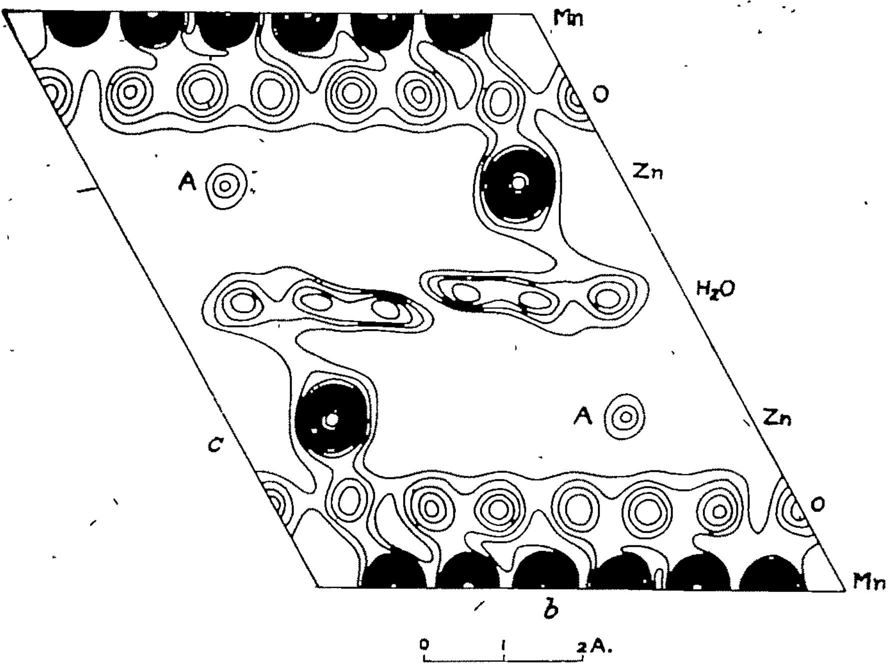

Fig. 1. Electron density of chalcophanite projected on the *b*-axis. Contours at equal but arbitrary intervals. The additional peaks *A* are located in the planes of the zinc ions

the water layer. The MnO_6- and H_2O-layers are close packed, and it is considered that weak hydrogen bonds of the type found for $Zn(BrO_3)_2 6H_2O$ by Yü and Beevers[1] bind the layers together. Zinc, situated above and below the vacancy in the manganese layer, is in one of four possible octahedral sites formed by the packing of these layers. Some idea of the structure is gained from Fig. 1, a projection of the electron density in arbitrary units on the *b*-axis of the crystal.

The density of 3·98 ± 0·02 gm.cm.$^{-3}$ observed for crystals of chalcophanite was found to be 0·15 gm.cm.$^{-3}$ higher than the value computed for the above formula, two units of which are packed into the unit cell. From Fig. 1 it is evident, however, that additional scattering material, not removed by subsequent difference Fourier summations, may be identified in the same sheet as the zinc. This minor peak, *A*, situated above a manganese atom, is located in another interstitial site between the layers. The formulæ for this mineral based upon the recorded chemical analyses[2] generally show an excess of manganese or zinc. If it is assumed that Mn^{2+} may be substituted isomorphously for Zn, the composition can be accurately expressed by the formula $(Zn, Mn^{2+})_{1+\delta} (Mn^{4+}_{3-\delta} Mn^{3+}_{\delta}) O_7 3H_2O$. Fractional quantities δ of divalent ions could occupy the new interstitial position when the other octahedral site *B* was completely filled by zinc. By sharing the oxygens already co-ordinated to Mn^{4+}, these ions would cause a redistribution of the manganese valency electrons in this neighbourhood, recorded as additional Mn^{3+} by chemical analysis. Values of 0·14, 0·22 and 0·25 for δ were computed for the analyses of chalcophanite in Dana[2].

Peak *A* has an electron density of 3–4 *e*.A.$^{-3}$. If this is assumed to be Mn^{2+} for purposes of computation, the empirical formula of this specimen will be $ZnMn_{3.1}O_7 3\cdot0H_2O$, giving 3·95 gm.cm.$^{-3}$ for the density, which is in good agreement with the observed value.

The atomic parameters of these interstitial ions have been determined. Only one is located in every four or five unit cells, and as there is no diffraction evidence for a larger unit, these are distributed at random. The structure is believed to represent a partial transition of stoichiometric $ZnMn_3O_7 3H_2O$ to that of another phase which appears to have higher symmetry. There is some evidence[3] that several hydrous oxides of zinc and manganese exist as minerals, and it is proposed to examine these in order further to clarify this system.

A more detailed account has been presented elsewhere for publication.

Influence of some Impurities, notably Potassium, upon the Reactivity of Iodine Pentoxide towards Carbon Monoxide

CONSIDERABLE quantities of highly reactive iodine pentoxide for use in the determination of carbon monoxide have been prepared successfully from iodic acid made by Lamb's chloric acid process[1,2]. Recently, however, batches giving both high and low initial reactivity have shown a considerable falling-off in carbon monoxide recovery, although the low blank determinations suggested good stability. It has been demonstrated that this poor performance is associated with the presence of potassium as an impurity in the iodine pentoxide.

The potassium originates from the barium chlorate used in the preparation of the chloric acid. Alkali metals, mainly potassium, have been found in the barium chlorate in quantities ranging from 0·5 to 1·5 per cent expressed as metal. During the manufacture of iodic acid most of the potassium is lost, but sufficient is retained to affect the reactivity of the iodine pentoxide towards carbon monoxide.

When contaminated iodic acid is dissolved in water, the potash reveals itself as a fine crystalline turbidity. Repeated filtration and recrystallization of the iodic acid have not produced iodine pentoxide capable of giving an initial reactivity better than 95–96 per cent, when using 10-gm. quantities. This apparently satisfactory reactivity deteriorated after

Added impurity	Percentage by wt.	Percentage reactivity			Remarks
		1–8 hr. after dehydration	24 hr. after dehydration	48 hr. after dehydration	
None		96–100	96–100	96–100	
'Analar' potassium iodate	0·5	38			An aqueous solution of pure iodic acid to which the solid impurity had been added was evaporated to moist crystals. These were dried in a desiccator and graded 14–25 B.S.
'Analar' potassium periodate	0·5	36	16		
Potassium iodate	0·5 max.	95	66		Prepared *in situ* by adding 'Analar' potassium chlorate to 25 per cent chloric acid made from triple recrystallized barium chlorate. Iodic acid prepared from this material by the method described (ref. 2).
Potassium iodate	Considerably less than 0·5	94	94	85	Freshly made solid potassium iodate added to a 25 per cent aqueous solution of the same batch of iodic acid from which the potassium iodate was prepared. Allowed to stand 24 hr. with occasional stirring, then filtered, recrystallized and graded.
Sodium paraperiodate	0·5	86	86	90	Freshly prepared material added to an aqueous solution of pure iodic acid, then treated as for 'Analar' potassium iodate and periodate above.
Sodium iodate	0·5	94	94	96	
Barium iodate	1·0	96	96	96	

a short time. Iodine pentoxide which will maintain a high and constant reactivity has only been obtained by removing the potassium impurity by double or triple recrystallization of the barium chlorate.

A limited series of experiments has been made on the reactivity of iodine pentoxide prepared from pure iodic acid to which various contaminants were added. The method of introduction of the impurities and the effects obtained are shown in the accompanying table.

It will be seen that the presence of either 'Analar' potassium iodate or potassium periodate in the iodine pentoxide resulted in a very low initial reactivity. Freshly prepared potassium iodate introduced by either of the methods shown in the table gives an iodine pentoxide with high initial reactivity which deteriorates gradually.

Sodium and barium iodates seem to have little influence on the reactivity of iodine pentoxide, but sodium paraperiodate appears to give an initial short-term effect. The high reactivity with sodium and barium iodates as impurities was maintained over several weeks. Blank runs were carried out between each reactivity determination, and in all cases low values not exceeding 0·3 p.p.m. of carbon monoxide equivalent were obtained. It is therefore evident that low blanks are no guide to the reactivity of iodine pentoxide.

To summarize, it is evident that iodine pentoxide intended for use in carbon monoxide determinations must be as free as possible from potassium. It must be re-emphasized that low blank determinations do not guarantee that the iodine pentoxide is highly reactive towards carbon monoxide, and therefore frequent reactivity checks should be made. Time has not allowed sufficient work to be carried out for any theoretical conclusions to be drawn.

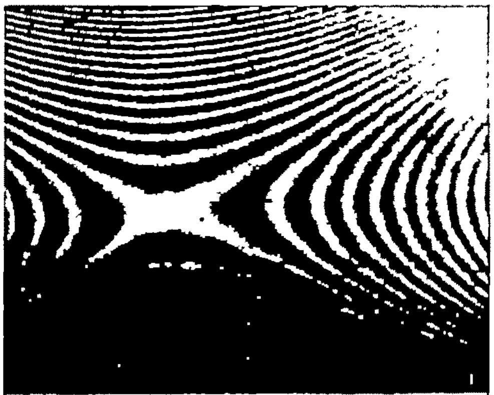
Use of High Contrast in the Photography of Interference Fringes

IN the course of some experiments on Poisson's ratio by Cornu's method[1], one of us (B. J. G.) used a photographic method of recording the observed fringes for sodium light. Ilford Thin Film Half Tone Panchromatic plates were used with Johnson's Contrast Developer, and it was noticed that the resulting pattern showed very fine white fringes on a black ground in the negative; comparison with visual observation showed that the recorded fringes were much sharper. It was concluded that this was due to the very high contrast of the photographic process used, and it appeared desirable to make a fuller investigation of this phenomenon. The use of high



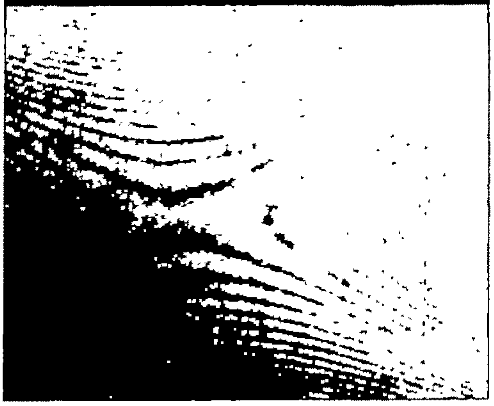


Fig. 1. Exposure of 80 sec. at an aperture of *f*/64

Fig. 2. Exposure of 160 sec. at an aperture of *f*/64

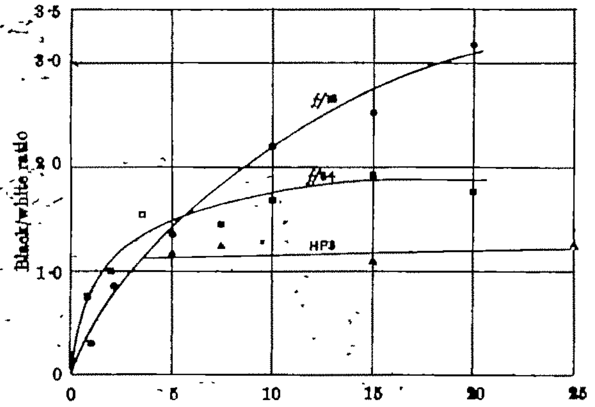

Fig. 3. Black to white ratio as a function of exposure-time

contrast is well known in the photography of subjects of low intrinsic contrast; but the possibility that variation of exposure would produce markedly different negatives seems to be little known and certainly is not widely used.

A series of plates was exposed at the same aperture but for different periods of time, and the plates were given identical treatment during development and fixing. In Figs. 1 and 2, prints are shown of two such plates, one of which had just over five times the exposure of the other; and it will be seen that in the positive print the black fringes become much sharper with the increase in exposure. In order to express the results in a quantitative manner, the ratio of the width of adjacent black and white fringes in the negative was measured, and Fig. 3 is a plot of the black/white ratio against the exposure time. Curves are given for apertures of *f*/16 and *f*/64 of the camera lens; but the exposure times for *f*/64 have been divided by 16 to facilitate comparison. In the same figure a few results obtained for an Ilford *HP*3 plate and the same processing conditions are also given.

It will be seen that the sharpness of the fringes using *HP*3 is practically independent of the exposure, but that the high-contrast system shows a marked change in the fringe-width with exposure. In the negative, a short exposure produces a narrow black fringe on a white background, and a long exposure produces a narrow white fringe on a black ground. (Figs. 1 and 2 show the same effect but are reversed because they are positive prints.) It would have been expected that the curves for *f*/64 and *f*/16 would have been identical after the *f*/64 exposure times had been reduced by a factor of 16; it will be seen from Fig. 3 that this is not the case.

By the choice of a suitable exposure, it is possible to produce very narrow white fringes on a black ground in the negative, and it is much easier to make measurements on such fringes than on the rather diffuse fringes normally obtained. It should also be possible to develop the use of high contrast to such an extent that approximate intensity measurements can be made: this should be useful in spectroscopic work where the expense of a spectrophotometer is not justified.

Dielectric Properties of Nitrocellulose - Water Gels

THE influence of interphasial polarization processe on the dielectric behaviour of aqueous dispersion has been frequently discussed. In earlier communications[1,2], I directed attention to a strikin effect of such a process, consisting of an extremel pronounced and broad dispersion region in the low frequency zone, characterized by a rise in permittivit of the order of 100,000 under maximal condition The exact nature of this process has not ye been established. It was thought that the sorbe water might exhibit co-operative orientation, althoug this remains questionable in the absence of theoretica support. While this work was mainly on coarse systems, it was pointed out that the effect is a important factor in the dispersion found in systems of colloidal and macromolecular structure a particular study[3] being made of gelatin gels in support of this view. This work has now been extende to nitrocellulose gels, in which we have found strongly developed low-frequency dispersion region presumably of this same nature. The gels wer measured in the form of membranes placed in aqueou solution, a procedure which has certain distinc experimental advantages.

The membranes were prepared from solutions o commercial nitrocellulose in 3/1 to 1/1 ether–alcohol the porosity being regulated in the usual manner by allowing more or less of the solvent to evaporate unde controlled conditions before the membrane was place in water. The measurements were made by clamping the membrane between the halves of a split conductivity cell and balancing in a calibrated resistance capacitance bridge, the results given being those obtained after the membrane had come int equilibrium with the bathing solution. Since the (platinized) electrodes did not touch the membrane the polarization at their surfaces could be taken int account by making measurements on the cell withou the membrane. Electrolytic polarization occurre also at the external surfaces of the low-porosity membranes, but its effect was always negligible i the frequency-range studied. The dielectric los factor tan δ was calculated after subtracting th D.C. conductivity (R_0^{-1} ohm^{-1} cm.$^{-1}$), which coul

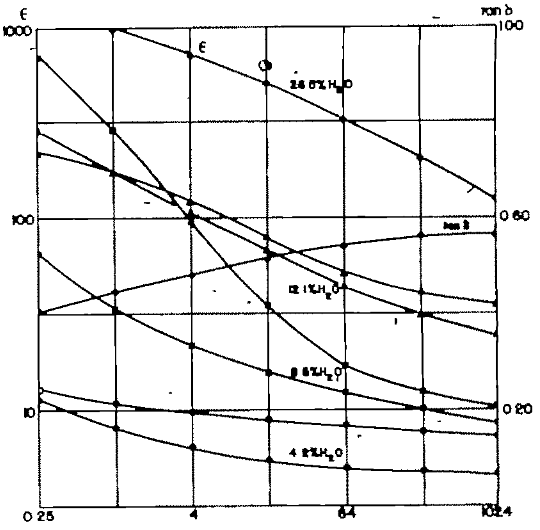

Fig. 1

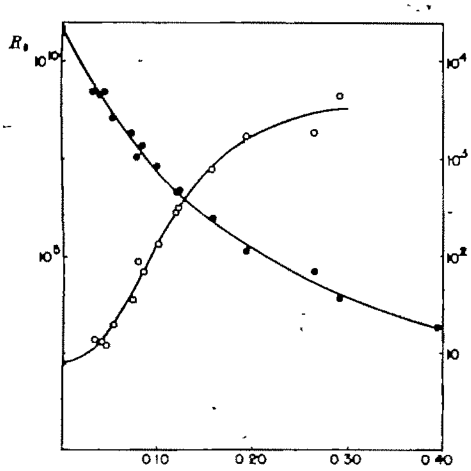

Fig. 2

be defined experimentally, provided voltage and time of observation were kept sufficiently low to prevent secondary changes in the membrane. The water content is given in grams water/c.c. of humid membrane[4] and was defined by drying at 85° C. in vacuum.

Typical results are recorded in the accompanying graphs, obtained on membranes prepared from Baker's U.S.P. collodion, measured in 1 per cent sodium chloride at 21·4° C. Well-dried membranes, of density 1·66–1·67, measured immediately after being placed in the cell, had a permittivity between 7 and 8, showed only weak dispersion and had a power factor of 0·02–0·03. The reliability of the frequency curves, particularly as affected by possible macroscopic heterogeneity of the membranes, was tested by reproducibility studies using substantial variations in the preparatory procedures.

The dielectric behaviour of the nitrocellulose gels is very similar to that of gelatin[2]: The dispersion is pronounced only when the water content is fairly high, the porosity curve (Fig. 2) having the same characteristic form in the two cases, determined by the small effect of the first firmly bound water. The dispersion reaches a maximum around 0·35 gm. water/c.c., at which point the permittivity is of the order of 5,000 at 250 c./s. The average pore radius of a gel of this porosity may be set[5] at 25 A., which may be taken as a rough measure of the thickness of the dielectrically effective surface water-layer. When the porosity is increased beyond this point, the dispersion becomes less pronounced owing to the decrease in internal surface area.

Since the permittivity apparently tends toward constancy at low frequency, the complete dispersion curves may be asymmetrical *S*-curves, which become broader and move toward higher frequencies as the porosity increases. Correspondingly, the power factor curves are, so far as the matter could be tested, characterized by single peaks—at the points of maximal slope of the permittivity curves—which become lower and broader as the porosity increases.

As in the coarser systems, nature and concentration of salt in the bathing solution had no appreciable influence on the dielectric properties, except when the concentration was very low, in which case the permittivity did show a noticeable decrease. This could be due, however, to a change in the distribution of (measuring) field inside the membrane.

This work was supported in part by a contract with the U.S. Office of Naval Research.

Budding of Erythrocytes in the South African Clawed Toad (*Xenopus laevis*) after Splenectomy

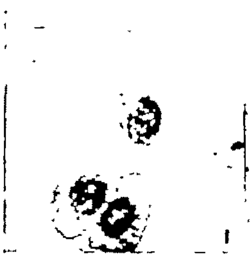
Budding of erythrocytes giving rise to non-nucleated erythroplastids in the peripheral blood was observed by Emmel[1] in ten out of eleven species of urodeles. One species, *Batrachoseps attenuatus*, has approximately 95 per cent non-nucleated erythrocytes[1,2]. Budding in the Anura is less well substantiated. Jordan and Speidel[3] described stages in the extrusion of the nucleus of erythrocytes of the bullfrog, *Rana catesbiana*.

In *Xenopus laevis*, no erythroplastids could be found either before or after splenectomy. However, after splenectomy, smears of peripheral blood showed nucleated erythrocytes which appeared to be budding (Fig. 1). Such cells were never seen in the peripheral blood or in liver or spleen smears from normal frogs.

These budding cells were to be seen in wet preparations of freshly drawn blood, and are therefore to be distinguished from the fragmentation of nucleated erythrocytes into plastids on standing of wet preparations, as shown by Dawson[4]. Standing of wet smears did not increase the number of budding cells of *Xenopus*, nor were any budding cells seen to complete the separation between the mother cell and the erythroplastid.

The budding cells have larger, more hyperchromatic nuclei than normal mature erythrocytes. Some erythrocytes which were not budding had similar large nuclei, and granularity of the cytoplasm at one pole (Fig. 2).

The significance of budding is difficult to assess. There is little doubt that the budding cells are not artefacts. Because of its large nucleus, one might regard the budding type of cell as juvenile. It might



1

2

(× 1,200)

be that budding is confined to the spleen, and that resulting erythroplastids are rapidly destroyed in the Anura, but persist in *Batrachoseps* and to a lesser degree in other urodeles.

Hatching the Contents of Cysts of *Heterodera rostochiensis* with Alternating Temperature Conditions

It is well known that the larvæ of the potato root eelworm, *H. rostochiensis*, are stimulated to emerge from the eggs contained in the cysts by a secretion from the roots of growing potato plants. This root diffusate can be collected and used in the laboratory. Anhydrotetronic acid is also an effective stimulant.

It has been found that an alternation of a high with a low temperature during the hatching of *H. rostochiensis*, with either root diffusate or anhydrotetronic acid, leads to a significant increase in the number of larvæ emerging from a batch of cysts.

Experiments have been conducted in which weekly counts have been made to observe the effect of hatching the cyst contents when: (*a*) a temperature of 25° C. is constantly maintained; (*b*) the temperature is lowered from 25° to 15° C. for 5 hr. twice a week; (*c*) the temperature is lowered from 25° to 15° C. for 5 hr., five times a week.

The results shown below were obtained from several experiments with potato root diffusate.

Number of Larvæ emerging from Batches of One Hundred Cysts (Mean of Four Replicates) after Twelve Weeks Treatment

Exp. No.		Constant temperature	Alternating temperature Twice a week	Five times a week
1	Non-vintage cysts*	5,730	11,157	13,201
2	Non-vintage cysts	6,232	8,355	11,118
3	Vintage cysts	11,370	17,580	26,819
4	Vintage cysts	13,126	18,421	26,324

* Vintage cysts are cysts of a known age.

A hatching treatment which includes an alternation of temperature probably offers conditions more nearly approximating to those in the soil than one in which the temperature is kept constant, and may help to obtain a complete hatch of larvæ from eelworm cysts.

Rate of Activity as a Function of Intertidal Height within Populations of some Littoral Molluscs

The physiological reality and profound ecological significance of the phenomenon of regulation of rate functions towards a constant, in response to maintained temperature differences, within the species in poikilotherms, has been widely recognized in recent times. Much attention has been directed in this connexion to a study of populations spatially separated by a wide range of latitude[1–3] or temporally separated by the annual cycle of seasons[4,5]. Indications of the existence of similar intraspecific differences between high and low members of populations of intertidal invertebrates are reported in the present communication.

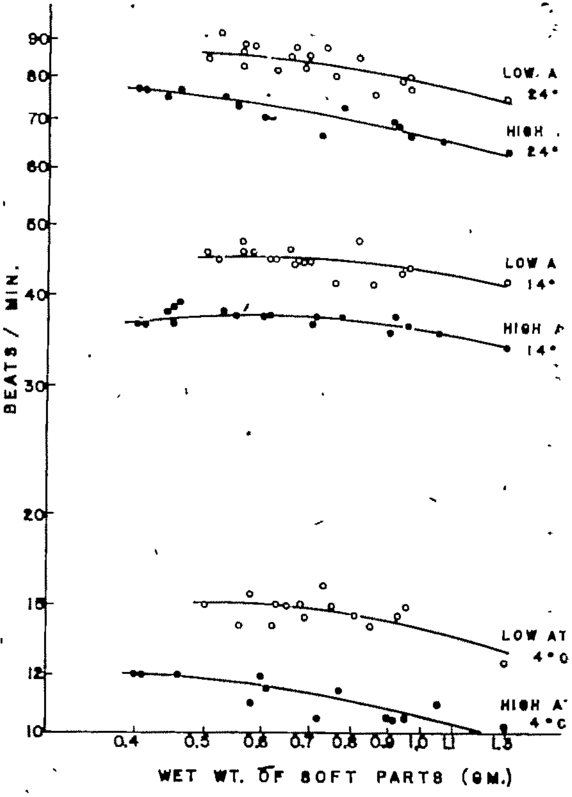

Fig. 1. Relation between frequency of heart-beat and wet weight of soft parts, at various temperatures, in *Acmaea limatula* from Palos Verdes, Calif. Open circles represent low-tide pool individuals from a permanently submerged level; filled circles represent mid-tide individuals from a level (3–4 ft. above zero datum, U.S. Coast and Geodetic Survey Tide Tables), submerged 40–50 per cent of the time. Points are averages of three readings for ten beats each

The lower in the normal intertidal range of distribution limpets of the species *Acmaea scabra* and *A. limatula* are collected, the higher the rate of heart-beat at any given temperature. This is shown, with weight controlled, in Fig. 1. The heart has been exposed by a trephine hole in the shell after which the rate of beat settles down shortly to a rather uniform value for many days. Counts were made three days after collecting and trephining; the animals were kept in the meantime in standing, aerated sea water at 14° ± 0·5° C., changed daily. Two hours was allowed for equilibration at each temperature. The regime of temperatures and of handling in collecting, operating and counting, while not critical, has been carefully standardized for the data on *A. limatula*. A few counts were discarded because of excessive locomotor activity or irregularity of heart-beat.

Mussels (*Mytilus californianus*) show the same relationships (Fig. 2) when rate of propulsion of water is measured by photoelectric estimation of clearing rate of dilute colloidal graphite suspensions[3,6]. Each point on the graph represents the average of three measurements for each individual in a group

5–15 mussels. Measurements were made within week of collection, the animals being kept in anding, aerated sea water at 15° ± 1° C. (interlal samples) or 11° ± 1° C. (deep sample).

This phenomenon is comparable to the differences und between populations of *Mytilus* of the same ecies from different latitudes[3]. The lower intertidal dividuals act like those from higher latitudes, or other words, appear to be cold-adapted relative those from higher tidal levels only a few feet away. e same is true of the 'deep' mussels from subtidal pulations. These and low-tide individuals, like ose from high latitudes, furthermore show less ight-dependence, allowing them to grow larger. hether the higher specimens are, in fact, exposed higher average temperatures, integrated, for exaple, in degree-hours or in some other way, is as t unknown.

The tendency of Q_{10} to vary systematically with e and habitat temperature in *Mytilus* and other ecies is discussed elsewhere[7].

Although differences between the samples of differt origin persist in the laboratory for weeks at a ven temperature, it is of considerable interest that eliminary transplantation experiments in the field one of us (E. S.) using *Acmaea limatula* have sulted in reversal in both directions within four eks. This is true not only of heart-rate but also the condition of gonads and of shell-weight relative weight of soft parts, both of which features are und to vary systematically with intertidal level or details in *Mytilus*, see Rao[8]).

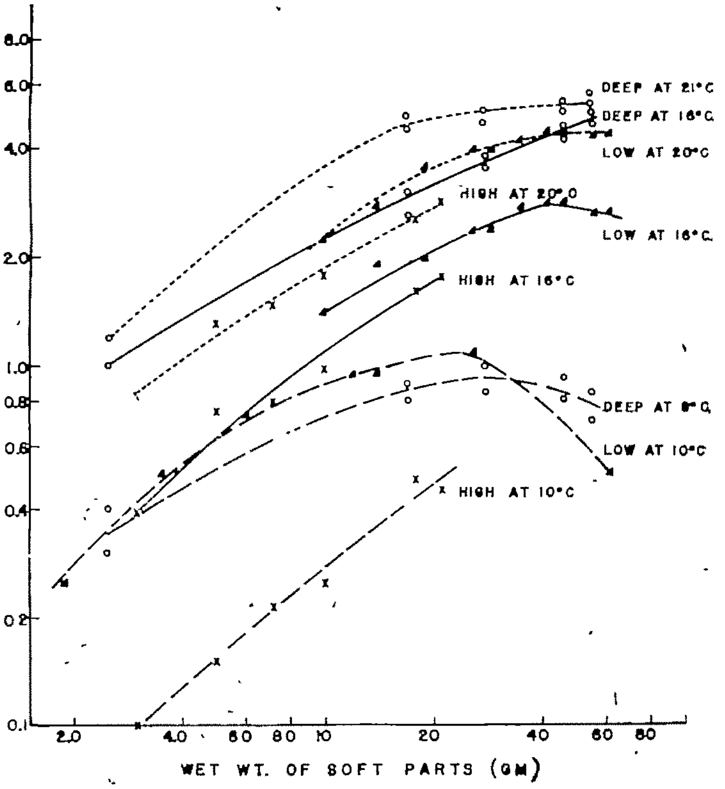

Fig. 2. Rate of water propulsion in three populations of *Mytilus californianus*, at three temperatures. Open circles from 'deep' water (80 ft.; off Pt. Vicente, Calif.); triangles, low intertidal (1–2 ft. above zero datum); crosses, middle intertidal level (4 ft. above zero datum; from pilings at Santa Monica, Calif.). For the low intertidal the data from Rao (ref. 3) have also been used. The degree of variation is indicated by the pairs of points for the deep mussels

A more complete report will be published elsewhere. Acknowledgments are due to Dr. Theodore H. Bullock for his interest and guidance, and for aid from a grant from the National Institutes of Health, U.S. Public Health Service.

Feeding Mechanism of an Ephemeropteran Nymph

A STUDY of the wood-boring and tubicolous mayfly nymph, *Povilla adusta* Navás. (Ephemeroptera, Polymitarcidae), common in the lakes of East Africa, has shown that it is remarkable in two respects.

Unlike any other Ephemeropteran nymph described, it lives in a tube lined with silk which it secretes[1]. It is also unusual in having a complex setal filter-feeding habit. A few other insects having the filter-feeding habit use setæ for the purpose; for example, larvæ of *Simulium* (Diptera), nymphs of *Oligoplectrum maculatum* Fourcroy[2] and *Brachycentrus nigrosoma* Banks[3] (Trichoptera) and *Isonychia* spp.[4] (= *Chirotonetes*) (Ephemeroptera). But all these forms are rheophilous and rely on the flow of water in which they live to bring their food. The nymph of *Povilla*, on the other hand, lives in the comparatively still water at the edges of lakes, inhabiting burrows in wood and the roots of water-plants and holes in laterite (personal communication from R. H. Lowe), and creates its own feeding current by movements of the gills.

The principal modifications associated with the feeding habits affect the mandibles and the forelegs. The mandible is unusual in possessing on the outer side a brush of filtering setæ, consisting of a *U*-shaped row of large alveoli from each of which springs a long pinnate seta. The forelegs bear similar brushes on the femora and tibiæ. Each femur bears anteroventrally a narrow oval ring of alveoli bearing the setæ, whereas the tibiæ each bear two brushes, one anterodorsal and the other anteroventral.

The setæ comprising all these brushes point somewhat forwards and practically occlude the lumen of the tube, the dorsal space being filled by a transverse row of pinnate setæ on the frons.

The feeding of the nymphs was observed by encouraging them to enter short lengths of glass-tubing in Petri dishes full of water placed under a binocular microscope. When entering a new tube the nymphs usually spin a silken lining to the tube. The silk is produced from the oral region and drawn out by flicking movements of one of the forelegs. The presence of this lining in the natural burrows of the nymphs was first noted by Arndt[1], but further work remains to be done on this aspect of the insect's biology. In glass tubes and possibly also in burrows in wood, this lining of silk enables the animal to hold itself firmly in position by means of the short stout setæ on the outer sides of the hind femora, which are pressed against the walls of the tube.

During feeding, the gills, which are borne in pairs on the first seven abdominal segments, beat rhythmically for a few seconds at frequent intervals, producing an intermittent current of water from the anterior end. Any floating organisms or pieces of debris which are large enough are caught on one or other of the filtering brushes, from which they are removed by the palps. Food is transferred from the brushes to the mouth by two distinct series of movements. The transfer of particles from the brushes to the palps is accomplished by simultaneous wide sweeping movements: (1) by the maxillary palp of one side, removing food from the mandibular brush of that side; (2) by the maxillary and labial palps of the opposite side, collecting food from the tibial and femoral brushes respectively; this action is accompanied by an inward flick of the leg which brings the brushes within reach of the palps.

These movements alternate from side to side and are separated by the second type of movement of the palps which brings the food to the mouth. Here the maxillary palps move in a transverse plane and push food towards the apices of the labial palps. The latter, swinging up and down on the basal joint, push the particles of food backwards and upwards to the mouth. By these means food is collected from either side of the body according to the following scheme: (1) mandibular brush to maxillary palp; (2) palps to mouth; (3) leg brushes to maxillary and labial palps; (4) palps to mouth.

The only pinnate setæ which are not swept by the palps are those on the frons, and these appear to be neglected. Possibly they serve to deflect the water current towards the other more ventral filterin brushes.

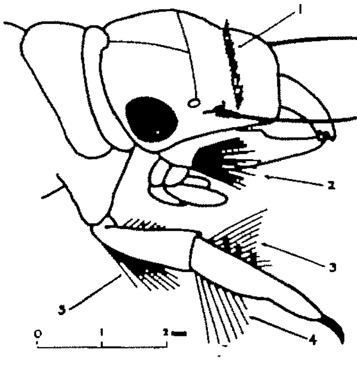

Fig. 1. Positions of filtering brushes in *Povilla adusta*. 1, Frontal brush; 2, mandibular brush; 3, dorsal tibial brush; 4, ventral tibial brush; 5, femoral brush

Further details of this work will be published el where, together with results of studies of oth aspects of the biology of this species. I wish to tha Prof. L. C. Beadle for his encouragement and advic and also Mr. D. E. Kimmins for identifying th species for me.

Chemical Examination of the Piltdown Implements

In the report[1] on the main results of o re-examination of the Piltdown material, we ga reasons for regarding the chromate staining of t *mandible* as indicating a deliberate attempt to mat a modern bone with the mineralized cranial fra ments. The actual composition of this bone (3·9 p cent nitrogen, less than 0·03 per cent fluorin suffices to prove its modernity; but the chromate staining, combined with the artificially abrade appearance of the molars, indicates that it is n only modern but also fraudulent.

In case there is any lingering doubt that the Piltdown finds are in part fraudulent, we think that on other fact now brought to light should be publishe immediately. Suspecting that some of the so-calle implements[2] reported from the site might have bee 'doctored', we asked Mr. E. T. Hall, of the Clarendo Laboratory, Oxford, to test the composition of their surface stains by means of his X-ray spectrographi method of analysis. He has reported to us that the stains on these flints are entirely ferruginous, wit one notable exception. The triangular flint (Reg. N E.606) recovered *in situ* from the layer immediatel overlying the skull horizon[3] is chromate stained. When this stain is removed in acid the flint appear greyish-white. It is indistinguishable from a mechanically broken piece of flint such as one migh encounter on the surface of any ploughed field in 'Chalk-land'.

Whereas a bone might have been dipped in a solution of potassium dichromate with the sole purpose of trying to harden it, a flint would onl have been treated in that way by a forger requiring it to be of a certain colour.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, December 14

Institution of Electrical Engineers, Radio Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Will Transistors Oust Receiving Valves ?"

Royal Society of Medicine, Odontology Section (at 1 Wimpole Street, London, W.1), at 5 30 p m.—Dr. K. A. Bisset: "The Bacterial Flora of the Human Mouth".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. Tom Harrisson: "Inside Borneo".

Tuesday, December 15

Royal Society of Arts, Commonwealth Section (joint meeting with the East India Association, at John Adam Street, Adelphi, London, W.C 2), at 5.15 p.m —Mr. Wilfred Noyce "Some Scientific and Technical Aspects of the Everest Expedition" (Thomas Holland Memorial Lecture).

Institute of Physics, Electronics Group (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. K. MacFadyen: "Electrical Breakdown in Liquids".

Society of Chemical Industry, Chemical Engineering Group (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. G. C. Eltenton: "Instruments for Quality Control".

Institution of Electrical Engineers, London Students' Section (at Savoy Place, London, W.C.2), at 7 p.m.—Mr. R. H. James: "A High-Voltage Laboratory".

Royal Aeronautical Society (in the Library, 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. D. L. Ellis: "Jet-Driven High-Speed Wind Tunnels".

Wednesday, December 16

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. J. Laurence Pritchard. "The Work of the Wright Brothers for Aviation".

Royal Meteorological Society (joint meeting with the Royal Astronomical Society, at 49 Cromwell Road, London, S.W 7), at 5 p.m —Discussion on "Stellar Scintillation". Opening speakers: Dr. H. E. Butler, Dr. M. A. Ellison, Dr. E. C. S. Megaw and Dr. J. Van Isacker (Belgium).*

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. Hermann Lehmann: "The Distribution of the Sickle Cell Trait in Africans and Indian Aboriginals".*

Royal Microscopical Society (at Tavistock House South, Tavistock Square, London, W.C.1), at 5 30 p.m.—Dr. R. W. G. Wyckoff: "The Electron Microscopy of Viruses".

Manchester Literary and Philosophical Society, Social Philosophy Section (in the University Staff House, Burlington Street, Manchester), at 7 15 p.m.—Dr. Redcliffe N. Salaman, F.R.S.: "The Social Impact of the Potato on the New and Old Worlds".

Wednesday, December 16—Thursday, December 17

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 10 a.m. each day—Conference on "The North Sea Floods".

Thursday, December 17

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m —Mr. J. H. M. McNaughton: "The Origin of the Northern Rhodesia Copper Deposits"; Mr. W. G. Garlick: "Reflexions on Prospecting and Ore Genesis in Northern Rhodesia".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. P J. Hilton: "Homological Algebra".

Television Society (at the Cinematograph Exhibitors' Association, 164 Shaftesbury Avenue, London, W.C.2), at 7 p.m.—Dr. E. C. Cherry: "Information Theory and Television".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7 30 p.m.—Scientific Papers.

Friday, December 18

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Papers on "Developments in Radio Aids to Surface Navigation".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. H. G. Conway: "Technical Features of the New British Standard System of Limits and Fits", Mr. G. J. Pearmain: "The Practical Application of the New British Standard System of Limits and Fits".

Institute of Physics, Industrial Radiology Group (at 47 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. W. G. King: "Magnetic Particle and Surface Penetrant Methods of Flaw Detection".

Society of Chemical Industry, Fine Chemicals Group (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Prof. D. H. R. Barton: "Steroidal Alkaloids".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Chemist (with university degree or equivalent and good experience in general analytical work)—The Chief Engineer, Middlesex County Council, Main Drainage Department, Mogden Works, Isleworth, Middlesex, quoting M.755T (December 19).

Assistant Experimental Officer (with a pass degree in botany or other suitable qualification) at the Welsh Plant Breeding Station, for work in grass and clover breeding—The Registrar, University College of Wales, Aberystwyth (December 19).

Lecturer in Agricultural Economics—The Registrar, Wye College, Wye, Ashford, Kent (December 19).

Senior Lecturer (with honours degree and good experience in technical teaching) in Mathematics—The Principal, County Technical College, Stoke Park, Guildford (December 19).

Experimental or Assistant Experimental Officer (with at least H.S.C. (science) or equivalent) at the Atomic Energy Research Establishment, Harwell, for work on problems associated with fundamental physical and metallurgical studies related to the design of fuel for nuclear reactors—The Establishment Officer, A.E.R.E., Harwell, Berkshire, quoting 2/103/19 (December 21).

Principal Investigational Chemist (university graduate or professionally qualified, and interested in the development of analytical methods and investigation of problems with a chemical background, related to steam and electricity generation), with the British Electricity Authority, London Division—Divisional Secretary, B.E.A., London Division, Generation House, Great Portland Street, London, W.1 (December 22).

Science Lecturer in the South Australian School of Mines and Industries, North Terrace, Adelaide—The Agent-General and Trade Commissioner for South Australia, South Australia House, Marble Arch, London, W.1 (December 24).

Research Assistant in Virus Diseases for research involving tissue culture of viruses—The Secretary of the University Court, The University, Glasgow, W.2 (December 26).

Assistant Lecturer in Chemical Engineering—The Registrar, College of Technology, Manchester 1 (December 31).

Electrical or Mechanical Engineer (with first- or second-class honours degree or equivalent in electrical or mechanical engineering, and at least three years postgraduate research experience), at a Ministry of Supply Design Establishment, near Sevenoaks, Kent, to lead section engaged in design and development of electrical and mechanical components and of complete control schemes for armament equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W.1, quoting D476/53A (January 1).

Lecturer in Bacteriology and Virus Diseases—The Registrar, The University, Sheffield (January 2).

Research Officer (with an honours degree in science with botany and chemistry as major subjects, or in agricultural science or equivalent qualifications), in the Commonwealth Scientific and Industrial Research Organization, Division of Plant Industry, Plants and Soils Laboratory, Brisbane, to undertake studies on the factors limiting legume establishment in sub-tropical areas and southern Queensland—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 146/34 (January 2).

Senior Scientific Officer or Scientific Officer (with good first- or second-class honours degree in chemistry, and preferably with special knowledge of, and experience in, one or more of the following fields: essential oils, perfumery materials, gums and resins, spices), to undertake laboratory investigations and to supervise the work of junior staff and intelligence work (Ref. F.651/53A); Experimental Officers (2) (with general certificate of education at advanced level in science, and preferably with some postgraduate laboratory or works experience in connexion with either insecticides and/or drugs of vegetable origin or the food canning or drying industries), (Ref. F.652/53A), at the Colonial Products Advisory Bureau (Plant and Animal), London, S.W.7—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting appropriate Ref. No. (January 2)

Lecturers in Electrical Engineering, Physics, Biological Sciences and Mathematics; Senior Lecturers and Lecturers in Inorganic Chemistry, Mechanical Engineering, Metallurgy (Physical), Metallurgy (Process) and Metallurgy (Mechanical), and a Senior Lecturer in Technology (Chemical and Metallurgical), at the New South Wales University of Technology, Sydney—The Agent-General for New South Wales, 56–57 Strand, London, W C.2 (January 4).

Lecturer or Senior Lecturer (with special interest and experience in agronomy) in Agriculture, at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (January 9).

Chair of Chemical Engineering in King's College, Newcastle-upon-Tyne—The Registrar, University Office, 46 North Bailey, Durham (January 18).

Lecturer (graduate in science or technology and with a good knowledge of the theory of structures) in Structural Engineering—The Registrar, College of Technology, Manchester 1 (January 20).

Professor of Agricultural Botany and a Professor of Mathematics—The Registrar, The University, Reading (January 25).

I.C.I. Research Fellowships in Biochemistry, Chemistry, Engineering, Pharmacology or Physics—The Secretary, The University, Edinburgh (February 15).

Lecturer in Pure Mathematics—The Secretary, Queen's University, Belfast (February 15).

Lecturer in Forestry—The Secretary, The University, Aberdeen (February 28).

Plant Pathologist (with honours degree in botany, and postgraduate experience in plant pathology, and preferably with experience in tropical plant diseases, especially those of the sugar cane) at the Mauritius Sugar Industry Research Institute—The Director, Mauritius Sugar Industry Research Institute, Reduit, Mauritius (March 31).

ASSISTANT DIRECTOR to take charge of a team of mathematicians, physicists and chemists, engaged on a comprehensive scientific study of the physical and chemical properties of rayon and synthetic fibres—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester

ASSISTANT PROFESSOR IN THE DEPARTMENT OF ELECTRICAL ENGINEERING—The Head of the Department of Electrical Engineering, University of British Columbia, Vancouver, or The National Research Council of Canada Representative, Africa House, Kingsway, London, W.C.2.

ENTOMOLOGIST (with a university qualification with entomology as a special subject) at the Tsetse Control Unit of the Veterinary Department, Government of Nigeria, for work on the control and eradication of tsetse fly in relation to Trypanosomiasis of cattle—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.67/14/02.

HONOURS PHYSICIST for research on the friction and lubrication of textile materials—The Director, Shirley Institute, Manchester 20.

LECTURER (with qualifications in agricultural botany, or in botany with bacteriology or zoology) IN THE BIOLOGY DEPARTMENT—The Principal, Seale-Hayne Agricultural College, Newton Abbot, Devon.

PHYSICIST (with a good honours degree) to assist in research into the fundamental principles underlying the processing of textile fibres into yarns—The Secretary, The British Jute Trade Research Association, Kinnoull Road, Kingsway West, Dundee, quoting N.1.

PHYSICISTS (with a good honours degree and some experience or training in research), for work on textile problems—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester.

SCIENTIFIC OFFICER (with at least a good second-class honours degree in entomology, and preferably with some knowledge of mycology), at the Forest Products Research Laboratory, Timber Borer Research Unit, Princes Risborough (but may be required to visit W. Africa), to investigate pinhole borer beetles and associated staining fungi in timbers—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.61/11/01.

SCIENTIFIC OFFICER (with first- or second-class honours degree or equivalent in mathematics or physics) at an R.A.F. Station near Oxford, for operational research duties in connexion with aerial photography—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.312/53A.

SENIOR LECTURER IN PHARMACOLOGY—The Registrar, College of Technology and Commerce, The Newarke, Leicester.

SOIL SURVEY OFFICERS (with university degree in geography, and preferably with a knowledge of chemistry, and interest in botany and plant geography), in Nigeria, for field work in connexion with a scheme of systematic classification and mapping of soils—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.63/14/021.

SCIENTIFIC MAN-POWER AND SCIENCE-TEACHING

IN opening an adjournment debate in the House of Commons on the shortage of science teachers on October 21, Mr. Bernard Braine quoted Mr. Robert Birley's statement in his presidential address to Section L (Education) at the British Association meeting at Liverpool, to the effect that the shortage is so serious as to render futile any talk of developing the scientific strength of Britain or any planning of institutes of technology or the like until it is remedied. Mr. Birley's address, however, was not the only one at the British Association meeting which directed attention to this shortage, nor was the passage quoted by Mr. Braine possibly the most important remark which Mr. Birley made in this connexion. One reason that Mr. Birley gave for regarding the shortage as serious was that more teaching of science in the grammar schools is desirable not merely to ensure a sufficient supply of scientists but, not less important, to help provide those entering on other careers with some understanding of science. Mr. Birley believed that the inability of the Civil Servant to understand the scientist is a more serious danger than that of the scientist to understand the Civil Servant.

The question of the shortage of science teachers should, in fact, be approached from this wider angle, and other references at the British Association meeting, notably Mr. E. Yerbury's address on the teaching of science in schools (Section X, Assembly of Corresponding Societies) and Prof. G. R. Clemo's presidential address to Section B (Chemistry), together provide the right perspective. Mr. Braine, indeed, covered the ground very reasonably. Like Mr. Birley, he recognized that it is not entirely a matter of salary differentials. It will not suffice, even if it were possible to avoid the attendant difficulties and repercussions, to raise the salaries of science masters to a figure high enough to counteract the financial inducements of industry. Other factors also help to determine whether or not able scientists enter the teaching profession.

Mr. Braine stressed two points, both of which were emphasized by Prof. Clemo. First, he thought that there is a general impression that the prospects of a headship are less for a science teacher than for an arts teacher. Prof. Clemo had remarked on the absence of science headmasters in our grammar schools: of twenty-five such schools in Newcastle and Northumberland, only four had headmasters who had graduated in science and two others had headmasters who had graduated in mathematics; of the remainder, ten had graduated in classics, three in English and three in history.

More important in Mr. Braine's view is the fact that a teaching career deprives the honours graduate of opportunities for specialist study and facilities for research. Here again Prof. Clemo also suggested that the universities could possibly make science-teaching more attractive as a career by encouraging research by science masters in schools. He referred to the research which was carried out, to their great credit, at Clifton College and Dulwich College in the latter part of the nineteenth century. A paper on research in schools which Dr. A. G. Lowndes read before Section L (Education) at the Birmingham meeting of the British Association in 1950 was, in fact, concerned with research carried out by the actual teaching staff and not by the pupils themselves, and he referred specifically to the occasional publication in the *School Science Review* of articles based on research carried out by the authors in schools.

In this connexion, Mr. Braine suggested that the practice should be adopted of allowing the honours graduate, whether in science or in arts, at least one day a week for research, upon application to the local education authority; that liaison between such teachers and the appropriate universities should be encouraged; and that similar arrangements might be made alternatively to facilitate the graduate engaging in industrial research. He thought that great advantages might accrue from teachers participating in such research and from industrial research chemists assisting in teaching. If such graduates prosecuted their research at a university, then he considered that the cost of material and equipment should be borne by the university as in ordinary postgraduate research.

Mr. Braine is obviously advocating the extension to the science teacher of honours grade of some of the facilities for research and consulting work which teachers at some of the technical colleges have enjoyed, although the question of equipment and materials might prove less simple than he implied, and facilities for research grants might not be so readily available. His constructive suggestions, however, drew no reply from the Parliamentary Secretary to the Ministry of Education, Dr. Kenneth Pickthorn, who replied for the Government. He could only say that the urgency of the situation is fully appreciated by the Ministry and that the inquiry now being carried out by the National Advisory Council on the Training and Supply of Teachers would be finished very shortly. Meanwhile, in each of the past three years there has been a small increase in the number of men graduates teaching mathematics and science, and the number of women graduates has remained steady. A special return showed that during the twelve months ended October 1952 there was an increase of 2·6 per cent, from 8,278 to 8,490, in the number of teachers with degrees in mathematics and science employed full-time in all maintained and assisted secondary schools offering courses leading to the General Certificate of Education. Dr. Pickthorn admitted that the situation might well be worse in a few years time, and he also referred to the appointment by the Secretary of State for Scotland of a committee, with Sir Edward Appleton as chairman, to consider and report on the causes and effects of present and prospective shortages of teachers of mathematics and science in Scottish secondary schools and to suggest remedies.

Dr. Pickthorn ignored the suggestions made by Mr. Braine; but they merit careful examination, both in the light of Dr. Lowndes's comments and of the observations which Mr. Yerbury mad to the Assembly of Corresponding Societies a Liverpool. Dr. Lowndes took the pragmatic view that if a science teacher undertook research, the primary objective should be to increase his efficiency as a teacher of his own particular subject: a school master's research work, he maintained, must be dictated by his own branch of teaching. It might be added that permission for the prosecution of research is more likely to be granted on such grounds by local education authorities than on the grounds o advancing knowledge.

Dr. Lowndes made it clear in his paper that he was not thinking simply of research carried out in the vacations, but of research carried out in term time in the school laboratories. While pointing ou very clearly that schools are not research institutions and are under no obligation to provide facilities for research, he argued that any man in charge of the higher teaching in any branch of science would increase his efficiency enormously by undertaking research. For that reason any efficient school should realize that it is to its advantage to encourage research; but Dr. Lowndes held that the initiative should come from the teacher and not from the school. Moreover, he thought that the ideal subject for research is some branch of study which incorporates biology, chemistry and physics with a little mathematics.

In thus stressing the importance of the subject-matter in relation to the interests and needs of the students in the higher forms rather than the interests of the science teacher *per se*, Dr. Lowndes made a point similar to that which Mr. Yerbury made at Liverpool in a slightly different connexion. Mr. Yerbury maintained that biology and general science rather than the physical sciences should constitute the approach and main content of science-teaching in schools, on the ground that these are more closely related to the environment and needs of the pupil. On this argument the content most in line with the needs and interest of the student is that which is most likely to afford the science teacher opportunities for research which can be carried out in school laboratories without excessive difficulties in regard to material or equipment.

If the encouragement of science teachers to undertake research in this or in other ways did no more than kindle or sustain enthusiasm, it might well be worth while. All depends, however, upon the quality of the teacher. An honours degree is no guarantee either of teaching ability or enthusiasm; and this factor must never be overlooked, no matter how far the practice of research in schools develops. The interests of the pupils must be the first consideration: if we can obtain the right men and women as science teachers and support them with the measure of public appreciation and understanding for which Mr. Yerbury pleaded, lack of funds is unlikely to stand in the way of their prosecution of research.

There is, however, a further aspect of research in schools which Dr. Lowndes specifically excluded from his paper but which may well be of increasing importance in this connexion. To the teacher with both the enthusiasm for his subject and the interest n his pupils which are essential, the carrying out of research by his pupils may also offer some genuine satisfaction. There have been a number of outstanding and successful examples of such research in recent years, and developments here may possibly be easier than along the lines indicated by Dr. Lowndes or Mr. Braine. The observations on the natural history of starlings recording the results of twenty-five years bird-ringing at Bootham School, York, under the direction of Mr. Clifford J. Smith, is one example of activities which the British Trust for Ornithology has done much to foster during the past twenty years. There is probably still room for more schools to co-operate in such field investigations; nor are the opportunities offered by the Field Study Centres of the Council for the Promotion of Field Studies as yet fully utilized even by the schools in the regions in which the Centres are situated. Such ventures as the oceanographic expedition in the North Sea organized early this year for science sixth-form boys from the Watford Grammar School are examples of what a little enterprise and imagination can do both to indicate the nature of scientific work to the schoolboy and provide opportunity of participating in the making of observations of value to science.

Other examples of such activities may be seen in the British mountain weather survey completed early in September, in which for some twelve weeks five high-altitude weather stations in the Cairngorms were manned by teams of undergraduates and senior schoolboys. This survey, which it is hoped to extend into other seasons, is of a type which should appeal to schools and to science masters looking for some form of investigation of scientific value. In the Brathay Exploration Group, both schoolboys and boys from industry have been co-operating since the summer of 1947 in field studies of the tarns, and especially the corrie tarns, in the Lake District, as well as in similar observations on an expedition to the Jotunheim in 1950. The schools meteorology scheme of the Royal Meteorological Society also offers the possibility of achieving work of real value to science, provided enough schools co-operate to make the study sufficiently representative.

While developments along such lines hold promise of satisfaction to the science teacher anxious to contribute to the advance of science as well as of furthering a keener appreciation of the true nature of scientific work on the part of the scholars engaged in it, too much weight must not be given to the factor of research in considering the question of the supply of science teachers. It should not, indeed, be disdained, as it was by Dr. Pickthorn. The initiative should rightly come from the science teacher, and the Minister of Education should not only be thinking about how to get a sufficient supply of science teachers keen and enthusiastic enough to be willing to undertake research: she should also be making sure that when they show such initiative it meets with an appropriate response—that it is encouraged by authority and not discouraged or thwarted.

The Minister's first responsibility is to establish the real factors of the shortage. Mr. Birley was right to point out that an increased supply of scientists (or technologists) follows an increased (or an adequate) supply of science teachers and not *vice versa*, but the facts of the situation are still incomplete. The *Times Educational Supplement* in October quoted a statement from the Science Masters' Association that 115 science posts, in some 980 schools, were still unfilled and that during the past ten years 975 science teachers had left the schools for industrial or administrative posts outside the teaching profession. The former figure is an improvement on that of 250 such posts in secondary schools unfilled at the approach of the new school year in 1952; but figures obtained in this way are neither conclusive nor necessarily impartial. Moreover, while local educational authorities are naturally not anxious to give prominence to a difficulty which may involve them in higher salaries, science teachers themselves may tend to overstress the effect of the attraction of higher salaries in industry.

For this reason it is important that the report of the inquiry instituted by the Minister last June, through the National Advisory Council for the Training and Supply of Teachers, which has just been published, should be given urgent consideration. In any event, the Advisory Council on Scientific Policy expressed itself sufficiently clearly on the subject last year for there to be no excuse for ministerial delay in the meantime in considering measures by which the status and conditions of service of science teachers could be made more attractive. Any initiative either from industry or from the science teachers themselves should be welcomed and supported by the Ministry as well as the local education authorities. All such possibilities, including also the raising of the retiring age or utilization of the services of scientists retired from other posts, should be explored with imagination and vigour.

What is already clear is that the Minister must show much more courage and resolution than was apparent in Dr. Pickthorn's speech if the country is to be assured of the supply of trained scientists that British industry requires to maintain technical progress. The exact magnitude of the shortage may be as yet uncertain. The trend is unmistakable and has been confirmed from too many sources to be questioned. The imperative need is for early action —for some immediate transfusion of science teachers of high ability. We cannot wait, as Dr. Pickthorn seems inclined to do, for the difficulty to disappear. If the grammar schools cannot cope with the present generation of science pupils, they will still less be able to cope with the flood which, even Dr. Pickthorn admitted, will come in a few years.

Nor is the question one on which the future efficiency and productivity of British industry alone turns. As Mr. Birley noted, it is increasingly important that in the government service also there should be some clear understanding of the scientist and of the way science works. That, too, must begin in the schools, and there also must begin in each generation of pupils the task of creating that wider general understanding of science, its method, its potentialities and its limitations, which to-day is essential no less for the advance of science itself than for the realization of these full potentialities for human welfare that the application of science offers us.

A NEW ADRENAL STEROID

THERE has been a recently growing body of evidence that the isolated and characterized adrenal steroids do not themselves account for all the actions of crude adrenal cortex extract. Tait, Simpson and Grundy, working at the Middlesex Hospital Medical School, London, have devised a method for the assay of the influence of adrenal steroids on the sodium and potassium ion balance by estimation of the diminution in the ratio of sodium-24 to potassium-42 in the urine of adrenalectomized rats, over a two-hour interval after the administration of the radioisotopes. In this way they found that crude ox adrenal extract contains a substance which behaves chromatographically like cortisone but which has a much greater effect on the sodium and potassium ion balance[1]. A substance with similar properties was found to be present also in the blood of the adrenal vein[2]. Subsequent studies by Simpson and Tait and their colleagues have shown that a new adrenal steroid is responsible for these effects, and the provisional name of "electrocortin" has been suggested for this steroid[3].

The isolation of electrocortin has proved to be a difficult task, and Drs. Simpson and Tait have called into collaboration Prof. T. Reichstein, of Basle, and his colleagues, whose experience in the isolation of steroid substances is unrivalled. Dr. A. Wettstein and Dr. R. Neber, of Ciba, Ltd., Basle, also collaborated in this work, which has resulted in the preparation of pure electrocortin[4]. From one ton of cattle adrenal glands only 10–40 mgm. of electrocortin was isolated.

Electrocortin proves to be much the most active steroid so far available in maintaining an adrenalectomized dog in good health, being thirty times as active as 11-deoxycorticosterone acetate in this respect; 11-deoxycorticosterone was hitherto by far the most active isolated substance known in tests of this sort. In the sodium–potassium balance test devised by Tait, Simpson and Grundy, electrocortin is about one hundred times as active as 11-deoxycorticosterone.

Almost simultaneously, Mason and his colleagues at the Mayo Clinic, Rochester, Minnesota, have announced the isolation of a similar substance from ox adrenal extract[5]; while R. E. Knauff, E. D. Nelson and W. J. Haines, at the Upjohn Laboratories, Kalamazoo, Mich., have obtained a similar substance from pig adrenal extract[6].

Evidence about the structure of the new steroid is as yet fragmentary. It appears to be a C_{21} steroid with a Δ-4α-β unsaturated ketone grouping and an α-ketol side-chain at C_{17}. There is, in addition, a hydroxyl group the position of which has not bee determined, but which appears not to be 17α, 16α o β, nor 11 or 12 β. According to Knauff *et al.* the new steroid has little or no activity in th glycogen-deposition or eosinophil-depletion tests fo adrenal steroids. This observation would be i agreement with the absence of an 11 β hydroxy group.

In electrocortin we may well have the activ principle of the amorphous fraction of crude adrena extracts, the existence of which has been assume for some time. Although electrocortin is much mor active than deoxycorticosterone quantitatively, i seems likely that its actions will be qualitativel similar to those of deoxycorticosterone and of th amorphous fraction, and so any entirely new type o action will probably not be shown by electrocortin Nevertheless, the isolation of this new steroid springing as it does from researches at the Middlese Hospital Medical School, has provided the solutio to a problem of many years standing, and has opene up a new and important approach to the physiology of adrenal secretions.

It is unfortunate that the British pharmaceutica industry is poorly developed with respect to steroid preparation and chemistry, despite the excellent academic work in this field which has been carried out here during the past twenty-five years. Had the possibility existed in Great Britain of assisting the development of Simpson and Tait's researches on a large scale in industrial laboratories, we might have avoided yet another example of the necessity of transferring abroad for large-scale development an important new discovery made by British investigators.

DOMESDAY BOOK RECORDS FOR EASTERN ENGLAND

The Domesday Geography of Eastern England

By Prof. H. C. Darby. Pp. xiv+400. (Cambridge: At the University Press, 1952.) 55s. net.

THE Domesday Book contains so many figures concerning the size and value of land holdings, the extent of wood, meadow and pasture, and the existence of mills, fisheries and salt-pans for the greater part of England, that generations of historians have wished that this information could be incorporated in maps that would illustrate the physical appearance and something of the economic activity of England about the year 1100. What was lacking was time for the calculations and certainty as to the meaning of the terms in which Domesday quantities were expressed. Prof. H. C. Darby, as this volume of four hundred pages and the promise f four more to come show, obviously has the time, ut has he the certainty ?

In this century Domesday studies have done nore to suggest the manner in which the text was rranged from the original local returns, and to peculate on the purpose of the document, than to dvance understanding of its terminology. The ore of Domesday is still an unknown quantity. ts linear measurements are obscure. The value of and is expressed in terms that still escape us ; the lough-land remains an abstraction. While detailed tudy of the text has enabled us to remark upon the rrors of the eleventh-century clerks, it has done ittle to overcome certain problems they set posterity : t is not always possible, for example, to get the otal number of hides for a vill or hundred ; several ills may be grouped under one place-name, so hat the local density of stock and population is bscured ; features may be mentioned with the lace responsible for them in a fiscal, not a physical, ense—thus Prof. Darby is reduced to mapping ome salt-pans in Lincolnshire "where it was hysically impossible for them to have been located" p. 69), for he rightly maps the Domesday Book rrors and all, rather than incorporate the corrections of its commentators. The geographer is not even elped by the work done on documents associated with the Domesday Book like the "Inquisitio Eliensis", nor by the special treatment of Norfolk, Suffolk and Essex in the more capacious "Little Domesday" ; the figures he needs are as often confused as elucidated.

Prof. Darby liberally accepts these disadvantages. Plough-lands are so vague that "we cannot wholeheartedly accept them as giving a sure indication of the relative distribution of the arable land in different parts of the county [Lincolnshire]" (p. 43). "From the nature of Domesday Book it is likely that no two people will arrive at identical totals" of population (pp. 47–50). After plotting marshlands in Lincolnshire on a special map, he confides that "It is impossible to believe that the fenland did not contain many more stretches of marsh of some value in the economy of the villages of the county" (pp. 64–6), and his comment on a map of the fisheries is that "it is impossible to believe that these Domesday entries represented the total fisheries of eleventh-century Lincolnshire" (p. 68). In fact, "In the light of all the uncertainties, it would be more correct to speak not of 'the Domesday Geography of England', but of 'the Geography of the Domesday Book' " (p. 2).

What we have, then, are the data in Domesday Book "most relevant to an understanding of landscape and economic geography" for Lincolnshire, Norfolk, Suffolk, Essex, Cambridgeshire and Huntingdonshire arranged county by county with tables and maps plotting place-names, plough-teams, population, woodland, meadow, marsh (Lincolnshire, Cambridgeshire), fisheries, salt-pans, waste, sheep (Suffolk, Norfolk, Essex) and mills. These give a picture of the relative prosperity of different regions and the overall economic activity of the countryside that is not really misleading on the scale employed for the maps—12½ miles to the inch. At the end of each chapter is a useful general survey of the main geological divisions, and the book ends with a description of the eastern counties as a whole, with reference to each feature. Each carefully drawn map has its limitations carefully pointed out in the text, and the conclusions to be drawn from it are most temperately expressed. In Lincolnshire, it is shown, for example, that "In general, the areas of sparse population coincide with the areas of few plough-teams", and from a map giving the distribution of sheep (twenty to the dot) in Norfolk, it is stated that "the first thing that stands out is that there were fewest sheep where there was most wood". It is nice that someone should have done all this work, but one hopes that Prof. Darby will not wall up other qualities besides his humour in the monument that he is building to patient scholarship.

J. R. HALE

PLANT GROWTH-REGULATING SUBSTANCES

Plant Growth Substances

By Prof. L. J. Audus. Pp. xix+465+42 plates. (London : Leonard Hill, Ltd., 1953.) 42s.

THE discovery that 3-indolylacetic acid is a growth hormone of plants and that many structurally similar compounds can also affect growth processes has opened up wide fields of chemical, physiological and agricultural research. The volume of literature relating to growth substances which has appeared during the past two decades is already very extensive, and it was by no means an easy task to prepare an up-to-date and readable account of the subject within a single volume. The author has done this, however, in a most creditable manner. His book represents the first really comprehensive effort in this field ; others, which have been published in the United States, have dealt mainly with practical applications with somewhat superficial treatment of fundamental, chemical and physiological aspects. Another very welcome feature of this book is that proper attention has been devoted to the contributions of European as well as American workers in this field.

The basis upon which the book has been written is that a knowledge of the physiological principles underlying the action of growth substances is essential to all who are interested in these materials. Chapter 1, dealing with the nature of plant growth, gives an excellent introduction along these lines and leads logically to a consideration in Chapter 2 of the natural auxins and their functions within the plant. The evidence relating to the existence of auxins *a* and *b* is carefully and fairly reviewed. Methods of assessing the activity of auxins are also considered here. Although details are only briefly given, mention might have been made of the fact that, in general, synthetic growth substances only induce poor responses in Went's *Avena* test. In the *Avena* straight-growth test certain workers would question whether the presence of sugar is necessary. Moreover, Bentley's modifications of this test also deserve mention. The chapter which follows, dealing with chemistry of the auxins, is not to be regarded as an essential part of the book, being provided only for those with particular interests in these directions. The use of growth substances for specific agricultural purposes is well covered in Chapters 8–11. In all cases, the physiological aspects as well as practical applications are dealt with, though the author rightly avoids making detailed recommendations regarding concentrations, methods of application, etc. Full references, however, are given so that the interested reader can easily follow up these aspects. Chapters 12–15 provide interesting reading and reveal many important lines of research which so far have received far from adequate attention. Thus, it still remains to be shown whether a flowering hormone actually exists, and there is much to be discovered about naturally occurring growth inhibitors. Taken as a whole, the book can be said to serve the needs of all who are interested in this field of work. Certainly, the physiological approach is useful and stimulating to the chemist, and the physiologist likewise will find the chemical treatment satisfying. Yet the book is most readable and the aim of the author to cater for the layman as well as the scientist has been quite well achieved, there being a useful glossary of technical terms for those completely new to this field of study.

The volume is well produced with excellent photographs and diagrams. Many references to original work are given, and appendixes relating to the use of specific compounds for the rooting of cuttings, the setting of fruit, weed control and for preventing the pre-harvest drop of apples are provided.

This book is the best of its kind yet published and can be confidently recommended. R. L. Wain

SEEING THROUGH THE ATMOSPHERE

Vision through the Atmosphere

By W. E. Knowles Middleton. Pp. xiv+250. (Toronto: University of Toronto Press; London: Oxford University Press, 1952.) 68*s*. net.

THIS book replaces the author's well-known earlier and smaller volume, "Visibility in Meteorology", the second edition of which appeared in 1941. It is in no sense a third edition but an entirely new book, although most of the ground covered is the same as before. The reason for the change of title is interesting. As the author points out, "To the meteorologist '*the* visibility' means a *distance*—that at which it is just possible to distinguish a dark object against the horizon. It is now fourteen years since the writer began to press for a change in this illogical terminology, and his complete lack of success is probably only an indication that language is born, not made". The book is concerned with a much wider field than 'visibility' in this restricted sense; in fact, it deals with what have been well termed the photometric properties of the atmosphere and their measurement, and with those properties of the eye which affect the visual range.

The author is at pains to drive home his thesis that the present method of estimating 'visibility' is completely out of date, since it ignores most of the great volume of work carried out by physicists and others during the Second World War. This work makes it possible to predict with remarkable accuracy the range at which a given object can be detected, provided we know certain physical quantities concerning the atmosphere, quantities which can now be readily measured with fairly simple photometric apparatus.

The underlying theory is described in detail in two chapters. These are followed by a short chapter on the eye, and then come the chapters in which all that has gone before is synthesized and in which methods are described for determining the visu range of objects seen in daylight and light sourc seen at night. There is also a chapter on the colou of distant objects and the visual range of coloure objects. The last main chapter consists of descri tions, most often with diagrams, of instruments use for measuring the quantities related to visual rang Of these the chief are extinction and scatter. Man different types of telephotometers used for measurin extinction are described and criticized and then section is devoted to instruments which measu scatter. 'Visibility meters' are not ignored.

It is gratifying to note the evident and expresse appreciation of the author for the work carried ou in Britain during the War. Incidentally, as an inde of the stimulus which the War supplied, it is notabl that of the 420 papers listed by the author in hi bibliography, nearly one-half date from 1940 onward

"Visibility in Meteorology" was a classic, and t say that the present volume is a worthy successor i no mean praise, but it is fully justified. The subjec matter is not easy; but the exposition is clear an the style is excellent, while here and there are welcom touches which reveal the author's sense of humour The production is very good and the lavish use o paper such as to cause a jealous pang to many publisher and author in Britain. A British reade may regret the use of American terms, such a 'phototube' for 'photocell', and some other unfamilia words such as 'illuminance' for 'illumination', whil on p. 7 there is the misleading statement that th International Commission on Illumination ha adopted the term 'luminance factor' for both 'luminous reflectance' and 'luminous transmittance'. The very minor nature of these criticisms, however, only serves to indicate the high standard which the author has set himself and has achieved in a book which will be highly valued, not only by meteorologists, but also by others who are interested in the subject indicated by the title. John W. T. Walsh

JEAN REY'S PIONEER WORK ON OXIDATION

The Essays of Jean Rey

A facsimile reprint of the original edition of 1630. With an introduction by Dr. Douglas McKie. Pp. xliv+144+xlv–lxxxiii. (London: Edward Arnold and Co., Ltd., 1951.) 21*s*. net.

JEAN REY was a French physician, born at Le Bugue, a small town near Perigueux, in Dordogne, where he practised after graduating M.D. in the University of Montpellier in 1609. His claim to fame is that he anticipated, by some hundred and fifty years, Lavoisier's conclusion, first announced in 1774, that the increase in weight in metals on calcination is due to their combination with air. Rey, however, did not visualize combination in the sense proposed by Lavoisier and accepted to-day. His views were supported by one experiment only; but by means of this experiment he claimed, to use his own words, that "all opinions contrary to mine are utterly refuted". He discussed the effects of calcination in a little book entitled "Essays . . . sur la recerche de la cause pour laquelle l'Estain & le Plomb augmentent de poids quand on les calcine", which was printed at Bazas, near Bordeaux, in 1630. In 1775, immediately following the publication by Lavoisier of the first of his memoirs on the theory of combustion, attention was directed to Rey's book, with the suggestion that it was perhaps unknown to the chemists of that day. Occasional references had, however, been made to it, between 1630 and 1774, in the literature of chemistry—the earliest, indeed, by no less a person than the philosopher Mersenne. A correspondence between Rey and Mersenne resulted, and this has been reproduced in this modern edition of the "Essays". Nevertheless, later references were few, a fact that Dr. D. McKie, in his introduction to the volume, suggests may perhaps be attributed to scarcity of copies of the book itself, rather than lack of appreciation of its contents. The original edition was, probably, small and intended only for circulation among the author's friends. To-day the first edition is certainly very rare, only seven copies having been traced. Since 1774 a number of reprints and translations have appeared, but these too are not now easily obtainable.

The new edition reproduces the original text in facsimile, so that scholars may now read it in the original French, and the value of this reprint is greatly enhanced by Dr. McKie's introductory essay. In addition to the few facts known about Rey's life, the introduction contains bibliographical details of the earlier editions of the "Essays" and a critical appreciation of the work itself, and such influence as it may have had on the development of chemistry.

Much of the information contained in this essay is derived from sources not easily accessible, if at all, to the average student. Readers of Dr. McKie's studies in the history of chemistry need scarcely be told that he has been at great pains to seek it out, to check its accuracy, and to assemble it in readable form. His attractively produced reprint of the "Essays" should take rank as the definitive edition, at any rate so far as English-speaking readers are concerned, and as such it will be welcomed by librarians and students of the history of chemistry.

BIOLOGICAL PHILOSOPHY

Problems of Life

An Evaluation of Modern Biological Thought. By Ludwig von Bertalanffy. Pp. xi+216. (London: Watts and Co., Ltd., 1952.) 25s. net.

"THE future historian of our times," says Dr. L. von Bertalanffy towards the end of this book (p. 194), "will note as a remarkable phenomenon that since the time of [after] the First World War, similar conceptions about Nature, mind, life and society, arose independently, not only in different sciences, but also in different countries. Everywhere we find the same leading motifs; concepts of organization showing [that is, the concept of an organization which manifests] new characteristics and laws at each level, those of [that is, the concept of] the dynamic nature of [reality], and the [that of] antitheses within it". That the philosophy of organic naturalism has in general, during the past half-century, risen to the status of a dominant world outlook among men of science is, indeed, undeniable. The ideas of Whitehead, at least in their broader aspects, have been almost universally accepted; the controversy between vitalism and mechanism, which in the twenties was still flourishing, no longer attracts any attention; the *Gestalt* conception in psychology and physiology has proved itself. The problem now before scientific workers is the practical one of elucidating the relations between the 'organisms' at the atomic and molecular level, and the organic form of living things which they compose. Dr. von Bertalanffy is one of the foremost living theoretical biologists, Austrian by origin, who has been associated with the study and exposition of organic naturalism since his first publication in 1926. In recent years he has become what one might describe as 'the Woodger of Canada'.

The plan of the book begins by contrasting the conceptions of organic naturalism with the classical alternative. It then considers levels of organization, the present position of the cell theory, and the question, of supra-individual organisms. This is followed by detailed exemplifications from experimental morphology and neurophysiology, after which such hypotheses as the biological magnification of non-statistical microphysical events are discussed. The work ends with the demand for a new general theory of systems, and the promise that new logico-mathematical formulations suitable for organic phenomena have been devised and will be presented in a further book (p. 199). The present monograph is highly recommendable for younger scientists who have not been able to follow, during the past three decades, the development of the points of view now generally accepted.

This is not to say that one can lay down the book without certain feelings of dissatisfaction. In the first place, the translator has failed to rise to the level of the German original, published in Switzerland in 1949. It takes a certain acuity as well as goodwill to penetrate through his English to the value within it. For example, upon a single page (p. 171) the reviewer noted the following necessary substitutions: "methodological" for "methodical", "enunciate" for "enounce", "spiritual" for "psychic", "myth or" for "mythical", and "illusory" for "illusive". The text is full of sentences of this kind: "It is the peculiar hybrid position between science and poetry by which vitalism is sapped". If the whole book could be re-written in English, its value would be doubled. Indeed, in order to quote the passage used at the beginning of this review, the reviewer had to add elucidations. There are also a few irritating mistakes, such as the eternal confusion of J. B. S. Haldane with his father (p. 197).

But a more basic criticism is that Dr. von Bertalanffy, if intending to cover the whole field of organic philosophy, ought to have done more justice to Whitehead, even if Smuts and Lloyd-Morgan were treated shortly. He may have felt that this would have been to go beyond the bounds of that theoretical biology about which he wanted to talk; but even within them, there are certain fascinating subjects, such as the relation between thermodynamic theory and biological evolution, which are scarcely touched upon. However, there are obvious limits to what can be done in two hundred pages of fairly large type; and this book should in any event take its place upon the shelves of all biological libraries, both private and public. If it reached a few physicochemical ones also, that would be all to the good.

Joseph Needham

AUSTRIAN WOOD RESEARCH INSTITUTE, VIENNA

By Prof. JOSEF KISSER
Scientific Director

NO less than 37·4 per cent of the land surface of Austria is covered with forests—or 42 per cent with respect to the fertile areas. Austria, therefore, is not only in a position to satisfy her internal demand for timber, but also to export a considerable amount. The growing requirements of a continuously increasing population in Europe, on one hand, and the decrease in usable forests, on the other, raise the question of how the demands by the peoples for so valuable and useful a raw material can be satisfied in the future. It is therefore necessary to introduce immediately at the places of timber production measures which will make possible a greater rational output and utilization by the efficient use of the various kinds of timber, and which will effect economies and, at the same time, make the most of the timber residue by improving the existing technical processes, and by developing new methods for the mechanical and chemical processing of timber.

To deal with these many-sided problems, the Austrian Society for Wood Research was founded in 1947. The first task of this Society was to co-ordinate the endeavours of all Austrian scientific workers, both theoretical and practical, engaged on wood research and to found a scientific community. In order to overcome the problems allotted to it, the Society made use of the various facilities for research of the universities, scientific institutes and technical colleges, and generously subsidized their endeavours. In this way it became possible to arrange for numerous experiments in the field of timber research and timber utilization which proved to be of scientific and economic importance. Since many problems of timber research are, however, of a highly complex nature, and call for the closest co-operation of experts in many diverse fields, a number of scientific studies although of great importance to the timber industry, had to be laid aside for the time being, because no success could be guaranteed owing to the fact that many scientific workers and research institutes are at a great distance from each other.

In 1950 the Forest Commission of the United Nations Food and Agriculture Organization submitted a report to the Austrian Government recommending, among other things, that a more generous subvention should be allotted to timber research, and a separate institute should be founded for it. In accordance with this recommendation, and under the special patronage of the Ministry of Commerce and Reconstruction as well as on the recommendation of the timber industry, the Austrian Wood Research Institute was founded by the Austrian Society for Wood Research, the means being contributed by the funds of the European Recovery Programme, the Viennese Chamber of Trade, and through credits guaranteed by the City of Vienna. It is housed on the grounds of the Arsenal (see Fig. 1), the address being Wien 3, Object 212 (Austria).

The main task of the Wood Research Institute is to serve the interests of the Austrian timber industry

and to carry out scientific experiments with the view of improving the existing processes and methods, mechanical and chemical, in the manufacture of timber, and discovering new ways of utilizing timber. Apart from *ad hoc* researches, it is, of course, indispensable that fundamental investigations should also be carried out on the inner structure, chemical composition and physical properties of wood. The various investigations undertaken by the Wood Research Institute include problems raised by the scientific members of the Institute themselves, the solution of which is of interest to the industry, the further utilization and practical testing of new developments abroad, problems of general interest put to the Institute by the timber industry and, lastly, special development processes undertaken by special contract, for the sole benefit of individual timber manufacturers. The Institute is also an important centre of information and, in a suitable manner, puts at the disposal of the Austrian economy in general new knowledge and scientific results that have been obtained in the field of wood utilization at home and abroad. The work of the Institute is based on the closest collaboration of the various technical departments and their scientific staffs, and its lay-out has been considered with special regard to these matters. Only on the basis of such teamwork can each timber problem be dealt with from every relevant angle.

In order to eliminate overlapping with the work of other research organizations, the tasks of the Institute have been exactly defined. Research work starts the moment the timber leaves the forest and comprises all stages of treatment, manufacture and refinement until the finished product reaches the consumer. Indispensable collaboration with forest research is guaranteed by the fact that those concerned with forestry, especially the director of the Federal Station for Forest Research, Wien-Mariabrunn, are represented on the board of the Austrian Society for Wood Research, and are thus in a position to balance overlapping problems against each other.

With regard to its organization, the Wood Research Institute has been divided into a number of departments and sub-departments, each with its own director and scientific and technical staff. At present it consists of the following departments: microscopy and research on wood structure; chemistry of wood and chemical technology; chemistry of paper and cellulose; pests and protection of wood; physics of wood, including tests of strength; mechanical technology of wood; fibre boards and dowels; and, lastly, wooden constructions, together with all the necessary laboratories, fittings and workshops. For reasons of expediency, the management of the Institute has been split into two and consists of a scientific director responsible for all the scientific problems and the organization of scientific research, and an economic director whose concern is the administration and the technical problems of the Institute. This solution has the great advantage that the scientific director is able to devote all his time to his true work and is never bothered by administrative and commercial questions.

After very careful planning, the Institute was opened on October 22 this year, although the erection of the buildings had only been begun during July 1952, and the importance of the occasion was emphasized by the fact that the opening was performed by the Federal Chancellor, Herr Julius Raab. The Austrian Institute of Wood Research is the first research institute in Austria to serve a whole big economic field. The opening celebrations included three lectures: the electron microscopy of wood, by Prof. A. Frey-Wyssling (Zurich); the future tasks of mechanico-technological wood research, by Prof. F. Kollmann (Reinbek, near Hamburg); and problems and the importance of lignin research, by Dr. K. Kratzl (Vienna). The scientific content of these lectures stressed the range of tasks of the Wood Research Institute, namely, the cultivation of general and fundamental research and of research in the important fields of mechanics and chemistry of wood utilization. The lectures had a double importance, however, for the fact that the speakers represented three different countries, namely, Switzerland, Germany and Austria, fully underlines the hope for a close collaboration in Middle Europe in the field of wood research.

SCIENCE AND APPLICATIONS OF PHOTOGRAPHY

CENTENARY OF THE ROYAL PHOTOGRAPHIC SOCIETY

In celebration of its centenary, the Royal Photographic Society arranged an International Conference on the Science and Applications of Photography. The conference headquarters where nearly all the meetings were held was at the Institute of Education, University of London, and meetings lasted from September 19 until September 25. There were about five hundred members, of whom two hundred were from overseas; 161 papers were read. The proceedings were grouped into five sections, namely, *A*, photographic science; *B*, colour photography, kinematography, stereophotography, photogrammetry; *C*, technique and applications of photography; *D*, photomechanical processes; and *E*, history, literature and training in photography, photocopying techniques.

In addition to an address by the president of each section, so arranged that all members of the Conference could attend, public lectures were given in the evenings by Mr. Harold White on "Fox Talbot and His Achievements", by Dr. G. B. Harrison on "Photography in the Service of Science", by Dr. C. E. K. Mees on "Fifty Years Work on the Theory of the Photographic Process" and by Dr. Ralph Evans on "Creative Directions in Colour Photography". At the Conference Dinner, on the last evening, the Astronomer Royal, Sir Harold Spencer Jones, proposed the toast of "Photography", replied to by Dr. C. E. K. Mees.

The amount of material presented was considerable, and it is quite impossible to summarize it all in a reasonable space. The topics mentioned here, therefore, come mainly from the section dealing with the science of photography, and have been selected from those available mainly because they can be included in a fairly coherent account. The full proceedings, amounting to nearly half a million words, will be published very shortly. For this prospect the Society is indebted to Dr. R. S. Schultze, honorary secretary of the Conference. References to the papers from which material for this account has been taken are given as superscript numbers. The material between any two such numbers has been taken from the paper given under the second number.

Significance of Adsorption by Silver Halide Grains

The most prominent general feature of the contributions dealing with the theory of photography was the importance attributed to adsorption phenomena at the surface of the silver halide grains. The grains are prepared by precipitation and subsequent treatment as dispersions in gelatin solutions, in consequence of which a layer of gelatin with a thickness of about 35 A. is bound tightly on them. In order to extend the colour sensitivity of emulsions beyond the limits to which silver halides are naturally sensitive, dyes are added. These dyes are adsorbed to the grains. If a dye is not too tightly held, the adsorption isotherm often displays a break, and the absorption spectra of the adsorbed dye above and below the break may be markedly different. This is taken to indicate a change, from a 'non-co-operative' state in which dye molecules on the grain are relatively isolated, to a 'co-operative' one in which they are closely packed and exerting strong lateral interactions. In the latter state the dye molecules, which for the most part are longer and broader than they are thick, are stacked in a monomolecular layer with the molecules face to face, and on edge at a steep angle to the grain surface. The more tightly adsorbed dyes usually give adsorption isotherms approximating to the Langmuir form, and are presumably always adsorbed in the latter state, whatever the concentration of dye in the surrounding medium.

Gelatin in the dye solution hinders adsorption by the grains, slowing down the rate of adsorption and reducing the amount of dye adsorbed in equilibrium with a given solution concentration, except when the concentration is high and the grains are almost completely covered by a monomolecular layer in any case. The effect is reversible: grains dyed in weak gelatin solution and transferred to stronger gelatin solution acquire the same surface conditions as if they were dyed in the stronger solution. For one particular merocyanine dye the heats of adsorption (calculated from the temperature coefficients of adsorption) varied from 3,000 cal./mole at 7 per cent gelatin, to about 8,000 cal./mole at 0·16–0·2 per cent gelatin in the 'non-co-operative' state and about 9,500 cal./mole in the 'co-operative' state, and 12,200 cal./mole with no gelatin. On the assumption that adsorption of dye requires displacement of gelatin, the difference of 9,000 cal./mole between the highest and lowest values is presumably a measure of the heat of desorption of gelatin per dye molecule. Micro-Kjeldahl determinations of the nitrogen associated with dyed and undyed grains after centrifuging from 7 per cent gelatin solutions and washing gave direct indication of removal of gelatin on dyeing[1].

For a long time after the discovery of the colour-sensitizing action of certain dyes, those suitable for the purpose could only be selected by empirical trial. The same is still true to some extent: nevertheless, the general character which a dye must possess to be effective is becoming clear. Much the greater number of sensitizing dyes follow the general formula $A(-CH=)_n B$, where A and B represent heterocyclic nuclei, such as those of quinoline, benzothiazole, rhodanine, joined by a methine or polymethine bridge. Hydrogen atoms in the nuclei and bridge may be replaced by substituents. The nuclei themselves are planar or nearly planar in structure, and both experiment and theory suggest that they will lie in the same plane, in the most stable configuration, when linked through a conjugated chain.

If it is assumed that a dye molecule is plane, a nearer approximation to its true shape than that given by its chemical formula can be reached by making a drawing using standard van der Waals radii of the units in the formula. When all possible geometrical adjustments in position have been made and two parts of the molecule still overlap, then the dye cannot be plane. Sensitizing dyes are known of all characters in which the shape is graded from 'loose', where there is more than adequate room for the dye to take a plane form, through 'compact' where the components of the molecule are so large that a plane form is just possible, to 'crowded', where the molecule must be seriously distorted from the plane form. As a general rule, it may be taken that a 'crowded' dye is a poorer sensitizer than a 'compact' one, and that it absorbs light less strongly, though maybe only slightly so. It seems that planar dyes can arrange themselves on the silver halide grains edge-on and tightly packed more readily than crowded dyes, and that this is the disposition which leads to most effective transfer of the energy they absorb to the silver halide.

The general indications are that 'compact' dyes aggregate more readily than 'loose' dyes, as might be expected since they cannot vary appreciably from the form which they must have in the aggregated state. Poor sensitization is not, however, necessarily attributable to overcrowding. Negative substituents such as nitro- and acetyl-, introduced where they cause no crowding, usually lead to depression of sensitization, and other groupings, not negative, also have similar effects. Moreover, a dye does not need to be planar to be a good sensitizer; though the cases known suggest that the molecule must consist of a substantial planar part, groups not lying in the plane being twisted or rotated out of the plane[2].

The photoconductivity of the silver halide grains in commercial photographic materials can be measured if the strong electrolytic conductivity is balanced out. It is then found that the variations with wave-length of the light absorption, the photoconductivity and the photographic sensitivity are parallel. The energy absorbed by the dye, therefore, is made available to release electrons in the silver halide, after which point the processes leading to the creation of the latent image are identical, whether exposure is by light in the sensitizing or the non-sensitizing region of the spectrum. The absorption of sensitizing dyes in solutions frequently varies strongly with concentration, and at high concentrations many show a very strong narrow absorption band on the long wave-length side of the normal absorption. This '*J*-band' is due to the formation of long aggregates like 'linear' crystals, in which 'exciton' propagation of energy occurs. Close packing of the dye molecules on the grains is favourable to 'exciton' propagation, but such propagation must not be too easy or the energy is likely to be lost in unwanted ways. Certain compounds (among which are dyes) known as supersensitizers confer added effectiveness in colour sensitization. It appears that these must be such as to fit well into the structure of the dye layer, and also to cause a local distortion of the structure at which transfer to the silver halide can occur. Other compounds act as desensitizers, so that the 'exciton' energy is st. When the silver halide grains are dye-sensitized there is some loss of their natural sensitivity. This may be due to loss of electrons, which have been excited into the conduction band, to the dye, where they lose their energy and cannot assist in the production of the latent image[3].

Gelatine has a strong influence on the rate of development. If silver halide grains are free of gelatine they are, with many developers, reduced to silver whether they have been exposed to light or not. In the ordinary way, differentiation between exposed and unexposed grains is extremely strong as, of course, it must be if development is to produce useful results. The rate of development is controlled substantially by two factors, namely, AT, a statistical factor, and an exponential factor, $\exp(-E/RT)$, E being an activation energy. The ratio of the rates of development of exposed and unexposed grains is then $(A'/A'')\exp(\Delta E/RT)$. The difference in activation energy ΔE estimated from the temperature coefficients of development is of the order of 6–12 kcal./mole, and is not likely to be much affected by the adsorption energies, which are probably nearly the same for exposed and unexposed grains. Developers can often exist in non-ionized and ionized forms, and the activation energy will vary with ionization. If the developing agent is ionized, the factor A will also be influenced by the charge on the silver halide grain. This is negative in ordinary photographic emulsions, and, judging from the zeta-potential, imposes a barrier of the order of 50 mV. Negatively charged ions are subjected to repulsion, and only a fraction of them will have sufficient energy to penetrate the barrier, the fraction decreasing by an order of magnitude as the ionic charge increases by one electron. The rate of development should therefore be increased if the charge barrier were eliminated. This expectation was borne out by tests in which photographic material was bathed in an active quaternary salt, which reduces and possibly eliminates the charge barrier. These considerations neglect adsorption, but it has been shown that developing agents do adsorb to silver halide, for some dyes, adsorbed to silver halide, are displaced by developing agents. This is not always so, for if the dye and developer are in ionic form and of opposite sign, the developer may be adsorbed and bind the dye still more tightly to the silver halide[4].

Surface-active cationic substances which reduce the charge barrier at the surface of silver bromide crystals in emulsion can also lead to increases in rate of fixation by thiosulphate. The accelerating effect decreases as the concentration of thiosulphate is increased, and displays a maximum in relation to the concentration of surface-active agent[5].

The rate of development of metol when used alone is slow, and of hydroquinone, slower still. Together they develop rapidly. Two hypotheses have been put forward to account for this phenomenon of 'super-additivity'. One suggests that metol oxidized during the process of development is reduced to its original form by hydroquinone, the other that the low activity of hydroquinone arises because it is strongly ionized and cannot penetrate the charge barrier on the surface of the silver halide, but can do so if an intermediate product in the oxidation of metol is adsorbed to the silver halides. A new developer, 1-phenyl-3-pyrazolidone, behaves in a similar way to metol and in this case the formation of an intermediate when it is used alone is revealed by its red colour. The presence of hydroquinone prevents the formation of the red colour. Thus, the regeneration hypothesis seems likely to be sound, and indeed, other evidence strongly favours it. Nevertheless, some of the experiments described also suggest that the charge barrier is reduced so that hydroquinone also may take part in development in the mixed developer[6,7].

It has been shown that silver ions are adsorbed to silica or glass when hydroxyl ions are present, and that the material so produced is photosensitive. In silver bromide sols, silver ions are adsorbed from acid solution. If then the hydroxyl ion concentration is raised, the sol becomes more sensitive to light. This is probably due to the formation of a silver–hydroxyl complex on the surface of the silver halide. At high solution concentrations of hydroxyl ions, the number of hydroxyl ions adsorbed was found to be about one-fifth of the number of available ion-sites on the surface of the silver bromide. As this complex is photosensitive, it appears that two photolytic processes are possible, and may both occur in ordinary photographic materials; namely, transfer of an electron from the lattice of silver bromide to a surface silver ion, and transfer of an electron from the silver–hydroxyl complex. Silver bromide sols, with no gelatin, are further sensitized by allyl thiourea, when it is adsorbed without breakdown to the silver bromide crystals. The H. and D. curve then displays two parts: first a slow rise of opacity with increasing exposure, and then a very rapid rise. The first of these is attributed to the silver–hydroxyl complex, and the second to the silver halide crystal itself. Confirmation of this hypothesis is provided by the difference in colour sensitivity of the two regions of the curve[8,9].

The importance of the conditions at the surface of silver bromide crystals has been underlined by experimental results on large thin crystals. Previous work showed that such crystals were sensitized by very thin deposits of silver, gold and metallic sulphides. In further experiments, crystals sensitized in the above ways were dipped in inert gelatin solution adjusted in silver ion and hydroxyl ion concentration, drained and dried. The gelatin improves the stability of the sensitizing layers, decreases the fog and adds to the sensitivity, the additional sensitivity being greater the higher the hydroxyl ion concentration, and somewhat greater the higher the silver ion concentration. A similar kind of result is obtained when the crystal has not been sensitized beforehand. The sensitization by gelatin is much greater if the crystal is digested in warm gelatin solution for periods up to half an hour. The gelatin film was found to be detachable by re-immersion in gelatin solution. When it settled back on the crystal so as to cover a part of the crystal not previously covered, the sensitization was transferred with the gelatin.

Sensitization was found to be accelerated by known sensitizers of the reducing types, gold salts, and thiosulphate and substituted thioureas. Products of the sensitizing process are formed in the gelatin adjacent to the crystal surface, and on the crystal surface itself, those on the latter probably consisting of aggregates of silver, gold, silver oxide or silver sulphide. Of the two, the products in the gelatin layer are the more effective as sensitizers.

It has always been difficult to account for the apparent lack of recombination of positive holes (roughly speaking, bromine atoms left by electrons which have been raised to the conduction bands) and electrons in the Gurney–Mott theory of the latent image. The above experimental results lead to the suggestion that the function of the chemical sensitizer is to trap the positive holes created during exposure to light. The crystals formed during the preparation of photographic emulsions are supposed to consist of polyhedral blocks, slightly misaligned, the boundaries of which constitute severe local dislocations. These dislocations persist out to the surface, where they provide a region for localized separation of silver—the surface latent image. The internal dislocations can also provide sites for internal latent image[10].

The above description does not require the supposition that gelatin is occluded within the grains, which has been put forward to account for the existence of internal latent image. The supposition is unlikely to be true. If gelatin is completely removed from the surface of grains (by bathing in hypobromite solution), the internal gelatin, if any, can be released by dissolving the grains in thiosulphate and brought to a higher concentration by foaming. A modified Zsigmondy gold number test then shows that the average gelatin content is certainly less than one gelatin molecule to six grains. Many more than one-sixth of the grains can carry internal latent image. Thus, occlusion of gelatin is unlikely, and in any event not a necessary condition for the production of internal latent image[11].

The general tenor of the work so far described, therefore, has been to emphasize the importance of the conditions at the surface of grains, and, in considering how the latent image is produced, to pay at least as much attention to the mode of disposal of the bromine (the positive hole in the crystal lattice) as to the production of development centres by aggregation of metallic silver. The theory of latent image has returned part way to the old hypothesis that silver bromide grains become developable as a result of formation of sub-halides by the escape of bromine[12].

Some Chemical Aspects

Bromine and chromic acid solutions applied to photographic materials will make them less sensitive or, if applied after exposure, reduce the latent image capable of being developed. It was suggested that desensitization of weak sensitivity centres (that is, those requiring heavy exposure to convert to latent image) is a consequence of adsorption of bromine or chromate ions. Sensitivity centres more easily converted to latent image behave more like weak latent image, while strong latent image is oxidized[13]. The results may be taken as suggesting that weak sensitivity centres are special locations where silver is formed as a result of exposure; stronger centres already contain some silver, and true latent image requires a certain minimum amount of silver. This would be consistent with results of tests of various kinds on the fog produced by heavy sensitizing treatment. When sensitized by reduction (with stannous chloride) the fog has the properties of metallic silver; but when sensitized by sulphur-containing gelatin, its properties are more nearly those of silver sulphide[14].

It has long been known that sharp-edged, and especially contrasty, details in photographs are affected by diffusion of the developer and its reaction products. In black-and-white photography this causes distortions of tone-reproduction and even makes the photograph of a detail different in geometry from the original image. In modern processes of colour photography, which use three layer of emulsion, differently colour-sensitized and, in the final result, differently coloured, any one of th three layers may be affected by the developmen processes in the other two. The results seem to b fortunate: in most cases the colour quality i improved[15]. A yellow filter layer is necessary in colour films to eliminate blue light remaining afte the top blue-sensitive layer has been exposed. Th is usually of colloidal silver, the particles of whic accelerate the reduction of silver salts produce during development. In this way a colour fog i produced. It was by a study of this phenomeno in a commercial colour process that a speciall rapid process was worked out for the productio of copies of documents. In this process the unexpose silver salts of a negative emulsion are made t produce a positive silver image in a second emulsio in contact with it[16].

Physics of the Developed Image

There is still much interest in the capacity o photographic materials for reproducing detail, whic justifies leaving aside the main topic of surfac phenomena and mentioning something about wha is commonly called the physics of the develope image. The capacity of a photographic material t record fine detail is limited by the diffusion of ligh in the sensitive layer and the heterogeneity know as granularity or graininess. The best descriptio of the light scattering is the light distribution in th neighbourhood of a vanishingly small, brightly illuminated spot. This is difficult to measure experimentally, and it is customary to throw a thin lin of light on the sensitive layer and measure the ligh distribution thereby produced. The fall of intensity each side of the line is exponential. If an arbitrary function is assumed for the light distribution around a point, integrated to give the distribution for a line, and the integral equated to the exponential distribution observed, the nature of the arbitrary function may be completely determined, and it is then available for calculating the light distribution in other forms of image. Experimental tests are in as good agreement as can be expected, considering the difficulties of the measurements[17]. The amount of diffusion increases with thickness of the layer, but less so when the exposure is with light of short wave-length, owing to the stronger absorption.

In measurements of resolving power the aperture of the lens used to project the test image is important. If the aperture is low, the resolving power of the lens is limited; if the aperture is considerable, some of the image is out of focus by reason of the thickness of the sensitive layer, and this limits the resolving power. Consequently, maximum resolving power is observed at a medium aperture[18]. In autoradiography the resolving power is largely dependent on the thickness of the emulsion layer, and also on the thickness of the specimen and intimacy of contact[19].

The measurement of resolving power in radiographs is somewhat difficult because the preparation of suitable test objects is difficult. It has been found, however, that a mercury physical developer, to intensify the silver image, is capable of giving a deposit of mercury, in a photographic test object of a customary pattern, sufficiently opaque to X-rays to make satisfactory test objects for the purpose[20]. An interesting point is that colour photographs often ppear sharper than black-and-white photographs ith the same resolving power. Experiments were eported which indicate that the judgment of sharpess depends upon the saturation of the colours and he structure of the photograph[21].

TOXIC HAZARDS OF PESTICIDES TO MAN

FROM the time of his first appearance on this earth, man has been engaged in mortal combat by insects and other types of vermin. Through all the centuries of recorded time men have been plagued by insects, and literally millions have died of insect-borne diseases or of starvation, often induced by loss of crops directly attributable to various types of pests. Insect-borne diseases rank high, if not foremost, among the great public-health hazards of the world. For centuries yellow fever, malaria, plague, typhoid and dysentery, to mention only a few well-known examples, have brought misery and death to millions of humans, determined the outcome of wars, and in no small way affected the course of history.

Likewise, in the agricultural sphere insects, plant diseases, weeds, rodents and other pests exact an almost unbelievably heavy toll on all agricultural production. Estimates of crop-losses due to these pests may vary from as low as 10 to as high as 60 per cent of all agricultural production. While there is a paucity of statistically sound data to support any such estimates, it seems safe to assume that the tribute demanded and taken by pests is at least a quarter to a third of the world's agricultural output.

In days gone by, as more and more food was needed to feed an ever-increasing population, nations one after another sought to colonize new lands and thereby expand food production; but the door to this avenue of escape is practically closed. Now that there are no new lands to conquer, man shows signs of acquiring some sense with regard to developing a sound agricultural programme. Such a programme must abandon the age-old practice of exploiting—or as we say in the United States, 'mining' our fertile soils—and must provide for the adoption of sound scientific procedures, not the least of which is practical pest control.

Science has developed ways and means of combating most of the vectors of insect-borne diseases and many of the more important crop pests; but, unfortunately, in most cases the actual control of these pests involves the use of one or more of the rather toxic chemicals which may be objectionable from certain points of view.

Any attempt to evaluate such hazards as may be inherent in the use of pesticides should be predicated upon a rather thorough understanding of a few of the more-or-less axiomatic principles involved: (1) Practically all pesticides have toxic properties and are toxic to warm-blooded animals, including man, as well as to insects. If they did not have these properties, they probably would not control pests and therefore would not be good pesticides. (2) The fact that most pesticides are toxic to man and animals does not necessarily mean that they cannot be used safely. If one develops a proper respect for the toxic properties of a substance, it may frequently be used with greater safety than a much less toxic substance which is apt to be handled carelessly. (3) A careful distinction must be drawn between the terms 'hazard' and 'toxicity'. Toxicity is the capacity of a substance to produce injury, and hazard is the probability that injury will result from the use of the substance in the quantity and in the manner proposed. To be at all reliable, any estimate of the hazard involved in the use of a substance must be based not only upon a knowledge of its inherent toxicity, but also upon the details of its proposed use, as well. (4) To avoid hopeless confusion, one must distinguish between use or operation hazards, and residue or food contamination hazards.

Most individuals interested in the hazards associated with pesticide usage have read some of the charges brought against pesticides, and at least some of the arguments advanced in their defence. Obviously, the problems encountered in the introduction of new chemicals are not unique. In common with many other advances in science and technology, pesticides must be regarded with mixed feeling, in that on one hand they possess highly desirable and at times almost miraculous properties for good and, on the other hand, definite objectionable or undesirable characteristics capable of producing harm. The problem is so to balance these attributes and so to control the use of these chemicals as to secure the maximum benefit and the minimum harm. In no case should public policy be totally regulated or guided by either the optimist who sees only the Utopian pesticidal properties, or by the pessimist who sees only the most dismal potentialities for wanton destruction.

We must strive for an objective point of view wherein good and bad, desirable and undesirable, potential benefits and harm, will be brought into proper perspective and balanced one against the other. In so doing, let us recall that fire is at one and the same time man's greatest servant and potential destroyer. Let us be mindful that the automobile, now regarded as a necessity in daily living, is one of the greatest causes of accidents, maiming and killing thousands each year, to say nothing of causing extensive property damage, destruction of wild-life, and the pollution of the atmosphere with undesirable gases. Let us recall that most of the drugs and pharmaceuticals developed to ease pain, control or suppress numerous illnesses, and lengthen human life are, when improperly used, poisonous to the extent that they must be classified among the more toxic and dangerous of the chemicals known to man.

The real problem is basically one of education. Able scientists make available to us the basic attributes of most of these new chemicals in advance of their release. Every interested individual has both legal and moral responsibilities which should regulate his actions with regard to promoting the use of pesticides. Those who develop and those who test such new materials share a responsibility for the evaluation of their beneficial and harmful properties, and for making this information available to the public. Those who distribute such materials and/or make recommendations for their use should relay this information in full, emphasizing the harmful as well as the desirable properties. Those who apply and utilize the materials have the final and perhaps the greatest responsibility. Pesticides are made available to the public on the premise that they will be used in good faith and in accord with prescribed recommendations and precautions. It has been said a chain is no stronger than its weakest link; and thus in the last analysis, all the rules and laws that might be imposed to regulate the use of pesticides will be to no avail if the ultimate user does not recognize and fulfil his responsibility for using such materials only in accord with the recommendations prescribed by the manufacturer and/or the duly authorized officials of government agencies. If the ultimate user of pesticides does not at all times recognize that the inherent rights of his neighbour and fellow man must supersede any and all personal or selfish desires, no amount of legislation will correct such an evil.

The various hazards presumably associated with the use of pesticides have been the subject of public hearings, legislative investigations, and numerous formal and informal discussions. Few problems affecting public health and national welfare have received more widespread attention or provoked greater controversy. Unfortunately, in far too many instances the voices of prejudice and the fears and apprehensions expressed by learned scientists, who have ventured opinions in fields where they were not qualified to speak with authority, have been publicized as much as or more than the cold, hard data and scientific facts presented by competent scientists, all of whom are specialists in fields of endeavour related to pesticide use. This is particularly true of sections of the Press which tend to favour sensationalism.

As the controversy grows more heated and expressed opinions become more emphatic, a large segment of the public becomes confused and bewildered by the seemingly endless flow of contradictory statements, half-truths, and in some instances malicious misrepresentation. At this point the old adage, "A little knowledge is a dangerous thing", assumes a new significance. The timely appearance of a very excellent report, "Toxic Hazards of Pesticides to Man"*, prepared under the auspices the World Health Organization by Dr. J. M. Barne should do much to stabilize thinking and consolidat public opinion on this controversial subject. In very enviable style and manner, the author h clearly and concisely set forth an unbiased evaluati of the hazards associated with pesticide usage an has pinpointed each of the many ramifications the whole complex problem. Lest there be tho who might under-estimate the true value of th report, it should be noted that the author travelle extensively, studying conditions and conferring wit experts in many fields of endeavour in ten countrie corresponded with authorities in other parts of th world and reviewed a selection of more than s hundred publications bearing on all phases of t subject at hand before undertaking the task of preparing his report.

The desirability—if not indeed the necessity—f using pesticides to control the insect vectors disease and to control pests on growing crops an produce is clearly set forth in a manner that shoul be entirely acceptable to all concerned. It is doubtf if any entomologist, plant pathologist, chemis farmer, or pesticide manufacturer will or can tak any serious exception to the arguments advanced the conclusions reached: "There can be no dou that pesticides have proved of great value both i the control of insect-borne diseases of man and i the protection of his crops. Their use will probabl expand at least for a number of years in the absenc of better methods for controlling the pests agains which they are directed. New chemicals are expecte to appear but are likely to be submitted to increasingl rigorous experimental testing before they can supersede those in use today".

The operational or occupational hazards, both re and imaginary, encountered in the manufacture o primary active ingredients, formulation into preparations suitable for field-use, handling and application are clearly set forth, as are the various hazard that might be encountered by innocent bystande or third parties, including neighbours, trespasser agricultural workers, and the consumers of foo that might contain traces of pesticides. The genera trend of these discussions is perhaps well portraye in two brief quotations:

"In the light of existing knowledge, the polic with regard to residues in food should be one o enlightened caution. The advantages of using th pesticide as represented by improvement in th nutrition of a population must be set against th hypothetical risks incurred. Definite rulings on thes questions must await the slowly developing knowledg of how these chemicals act on the living body Meanwhile, it is well to consider how residue hazard may be reduced by means of proper controls."

"There is a possible risk to health from the ingestio of small quantities of pesticides in food, but there i no evidence that anyone has suffered illness from this cause. Difficulties in assessing this hazard exist but control would be relatively simple provided tha suitable methods of analysis were available."

It is significant that, like Drs. Hayes, Princi an other American toxicologists, Dr. Barnes repeatedl points out that the final answers to many perplexin uestions must in the last analysis be based upon uman experience; or in his own words "... a loser study of man himself . . .", and can never be btained from animal experiments alone. Certainly ur problems are far from completely solved and, ecognizing this fact, Dr. Barnes has made some very ppropriate suggestions and recommendations for urther research, justifiably stressing the need for a ore complete and thorough study of human xperiences.

---

* World Health Organization Monograph Series No. 16 Toxi Hazards of Certain Pesticides to Man, together with a Select Bibliography on the Toxicity of Pesticides in Man and Mammals. By J. M Barnes. Pp. 129. (Geneva: World Health Organization; London H.M. Stationery Office, 1953.) 7s. 6d.; 1.50 dollars; 480 Frenc francs; 6 Swiss francs.

There is always danger in the use of quotations taken out of context; but perhaps a few selected statements from the author's conclusions will serve to illustrate his point of view:

"None of the materials in use today is so inherently poisonous that its safe use is impracticable. . . . Some of the materials in use today are capable of producing severe and fatal poisoning if handled carelessly in the factory or during application. . . . Other materials are unlikely to produce acute or fatal poisoning, but because of their stability and persistence may remain in food and be consumed in small quantities over many years by the general public. Much anxiety has been expressed on this score, and it is certainly desirable that food should not contain foreign chemicals lacking any nutritive or beneficial value to man. Nevertheless, there is no evidence whatsoever that the ingestion of these materials in this way has produced undesirable reactions."

It is noteworthy that the conclusions reached in this paper are in very close general agreement with those released from time to time by the Food Protection Committee of the National Research Council in the United States.

The report also contains sections on "The Toxic Properties of Some Pesticides", "Control of Agricultural Pesticides in Different Countries", "Glossary of Names of Pesticides Used in the Text", and a bibliography of 689 titles.

As a parting word, Dr. Barnes's paper should be considered as essential for all who are in any way interested in problems associated with the use of pesticides. In a sense, this report is destined to become the Old Testament for a new but rapidly developing school of thought and philosophy.

GEORGE C. DECKER

OBITUARIES

Dr. L. F. Richardson, F.R.S.

LEWIS FRY RICHARDSON, author, in 1922, of "Weather Prediction by Numerical Process" and, in 1939, of "Generalised Foreign Politics", died at his home at Kilmun, Argyllshire, on September 30. These mentally adventurous works stamp the man, and of him it may be truly said, as Wordsworth said of Newton:

> ". . . a mind for ever
> Voyaging through strange seas of Thought, alone."

For it was given to Richardson to be way out ahead of his contemporaries in the effort to mould experience to scientific form. Some have now caught up, or are catching up, with the meteorological research which Richardson did thirty years ago; the fate of his pioneering efforts to form a science of international relations will perhaps not be known for a still longer time.

Richardson was born into a Quaker family in Newcastle in 1881. He was educated at Bootham School, the Durham College of Science at Newcastle, and at King's College, Cambridge, where he graduated in the Natural Sciences Tripos in 1903. He was three years at the National Physical Laboratory and three in the electrical industry before reaching meteorology. In 1913 he was appointed superintendent of Eskdalemuir Geophysical Observatory, and on leaving in 1916, to join the Friends Ambulance Unit in France, he had already completed the first draft of his work on weather prediction by numerical process. Here, on the hydrodynamical and thermodynamical equation of meteorology, he brought to bear a technique of arithmetical solution of partial differential equations by finite-difference methods on which he had written at length in a paper in the *Philosophical Transactions* in 1910. Richardson returned to the Meteorological Office in 1919 to work with the late W. H. Dines, and he then completed his great volume on the evolution of weather. Electronic computers could scarcely then be dreamed of, and Richardson had other dreams of how the job might be tackled, with tier upon tier of human computers fitted into an Albert Hall structure. His methods remained undeveloped for a long period, not merely because of the magnitude of the computing problem but also through lack of an adequate three-dimensional network of observing points in the atmosphere. Moreover, as we know to-day, Richardson's equations were not well adapted to the problem in some fundamental respects—they were too general. But a mighty vision had been displayed.

Richardson's other meteorological work sprang almost directly from his analysis of the weather prediction problem. He saw that, of the processes formally expressed in his equations, least was known and understood about the transformations of radiation in the atmosphere and about atmospheric turbulence. Observational studies of the former, in relation particularly to cloud and ground surfaces, went forward with hard theorizing about the latter. In 1920 he wrote a famous paper, "The Supply of Energy from and to Atmospheric Eddies", in which by thermodynamical reasoning he sought to show that the growth or decay of turbulence in a statically stable atmosphere depended primarily on the vertical flux of heat in relation to the vertical shear of wind. The analysis threw up a non-dimensional parameter involving these quantities, and now called 'Richardson's Number', which serves to correlate phenomena affected by atmospheric turbulence much as Reynolds's number provides a correlating parameter for isothermal flow in pipes, channels and around solid bodies. In 1926 he put forward an entirely new basis for the discussion of turbulence phenomena, aimed at that time at dealing particularly with a medium such as the atmosphere in which the turbulence spectrum extends indefinitely out to larger and larger wave-lengths. He showed that the laws of diffusion in such a medium could most soundly be arrived at not, as in earlier work, by the study of the scatter of individual particles, but through the variation in separation of pairs of particles—the separation at any instant defining the scale of eddy motion effective in changing the separation. His approach is essentially that developed much more recently by Kolmogoroff and others in the now lively development of a theory of turbulence. Richardson found from observations over a tremendously wide range of scale of motions that the coefficient of diffusion (in earlier nomenclature) increased as the four-thirds power of the scale of the diffusion process. This same 'law' has been inferred by Von Weizsacker, Heisenberg and others from current theory, and Richardson's last hydrodynamical paper, in 1952, was a return to this field of study.

Richardson's association with the Meteorological Office ended in 1920 when it became a department of the Air Ministry and he felt compelled to resign on grounds of conscience. He became head of the Physics Department at Westminster Training College and, in 1929, principal of the Paisley Technical College. His interest shifted in the late '20s and the '30s to international relations and the psychological factors leading to war, and to this end he equipped himself in 1929, when nearly fifty years of age, with a degree in psychology. He retired from Paisley in 1940 in order to prosecute this study more fully, and the results are largely contained, in micro-film form, in a revised edition of his 1939 volume on "Generalised Foreign Politics".

Richardson was honorary secretary of the Royal Meteorological Society during 1921–24, a D.Sc. of the University of London and was elected Fellow of the Royal Society in 1926. He was a patient and original teacher, delighting in ingenious practical demonstrations with simple apparatus. His writings were utterly individual in style and highly entertaining; but few concessions were made to the reader. A fellow undergraduate at King's College said of him, "Lewis was a rock and flew his colours with superb, audacious gallantry". The audaciousness became with the years an understanding gentleness, but the superb gallantry increased. He married Dorothy, daughter of the late Dr. William Garnett, by whom he is survived with their two sons and daughter.

P. A. Sheppard

Prof. E. Bataillon

Eugène Bataillon died on November 1 at the age of eighty-nine. He started his scientific career in the Faculty of Sciences at Lyons, his first publication on amphibian embryology appearing in 1888. Afterwards he became professor of zoology at Dijon and, after 1918, professor in the University of Strasbourg. Later he became professor of zoology in the University of Montpellier, where he remained until he retired in 1932. He was a member of the Paris Academy of Sciences and received a number of prizes, including the Prix Osiris.

Bataillon covered a wide field of experimental cytology, including studies on the parthenogenetic activation of amphibian, lamprey and fish eggs, on morphogenesis and evolution, on the effect of heat on the gametes of the frog, on interspecific and intergeneric fertilization, on polyspermy and on the electrical properties of unfertilized, activated and fertilized frog eggs; but he became world-famous through his discovery that the unfertilized egg of the frog could be induced to develop parthenogenetically by puncture with a fine glass or metal needle. Bataillon found that this treatment was more successful when the needle was contaminated with blood or other foreign bodies. What is the nature of the stimulus exerted by these contaminating materials? Are they thromboplastic or must they contain nucleoproteins? This is a problem which is just as interesting to-day as it was when Bataillon first formulated it at the beginning of this century.

In a famous paper on traumatic parthenogenetic activation, published in 1910[1], Bataillon said: "Cette parthénogenèse effective chez un vertébré était, pour moi, un résultat inespéré. L'élevage des larves étant *en général* facile, un chercheur bien installé pourra peut-être aborder sur ce matériel la solution de problèmes fondamentaux"—a prediction which was confirmed by Loeb and Bancroft[2] when they announced in 1913 that a parthenogenetic frog, obtained by Bataillon's method, was a female. Bataillon went on to say: ". . . ce n'est pas au hasard que ces expériences ont été faites". I think Bataillon was stimulated to do these experiments by the belief that spermatozoa puncture or bore through the egg surface at fertilization. To-day we do not believe that this is the case and consider, rightly or wrongly, that after enzymes from the head of the spermatozoon have softened up the egg surface, the egg engulfs the spermatozoon, as in phagocytosis.

Whatever the reasons that prompted Bataillon to carry out his experiments, they remain some of the most exciting and important in cell physiology. Many experiments still remain to be done using the elegant technique he discovered nearly fifty years ago.

Rothschild

NEWS and VIEWS

Cavendish Chair in Cambridge: Prof. N. F. Mott, F.R.S.

Prof. N. F. Mott, Henry Overton Wills professor of physics in the University of Bristol, has been appointed Cavendish professor of experimental physics in the University of Cambridge in succession to Sir Lawrence Bragg, who is going to the Royal Institution (see *Nature*, May 9, p. 819). The departure of Prof. Mott from Bristol next autumn will end twenty-one years service to its University. Succeeding Sir John Lennard-Jones as professor of theoretical physics in 1933, he chose to take up fields of inquiry new to him, but suited to facilities in men and equipment available in the Wills Laboratory. Soon contributing to the theory of metals and alloys through his standard treatise with H. Jones, he was then led to the study of electronic processes in crystals with special reference to semiconductors, insulators and the photographic latent image. Since the Second World War he has been particularly concerned with the mechanical properties of the solid state. His work in all these fields has been marked by a flair not only for initiating and stimulating theoretical work, but also for guiding experimenters into new and exciting fields of laboratory study. Moreover, by organizing successful conferences and summer schools in the Wills Laboratory, he has done much to promote a wider interest in these subjects throughout the country. As a leader of a combined team of theorists and experimenters with a common purpose, he has no superior. When he succeeded Prof. A. M. Tyndall as director of the Wills Laboratory in 1948, Prof. Mott met his increased administrative responsibilities with equal facility. Indeed, his loss will be felt not only in the Wills Laboratory itself, but also by his colleagues in the faculty, and by others who, concerned with the future policy of a vigorous young University, have learnt to value his counsel and judgment.

President Eisenhower's Proposals for the International Control of Atomic Energy

In his speech to the General Assembly of the United Nations at New York on December 8, President Eisenhower said that the United States are prepared immediately to meet privately with such other nations as may be "principally involved" to seek "an acceptable solution" to the atomic armaments race. They would seek more than the mere reduction or elimination of atomic materials available for military purposes. The possibility of power from atomic energy for economic purposes is already proved, and President Eisenhower proposed that the Governments principally involved, to the extent permitted to common prudence, should begin and continue to make joint contributions from their stock-piles of normal uranium and fissionable materials to an international atomic energy agency to be set up under the ægis of the United Nations. This agency would be responsible for impounding, storing and protecting the contributed fissionable and other material and for devising methods of allocating the material for peaceful purposes; and the United States are prepared to undertake such explorations in good faith and to further the development of plans for expediting the use of atomic energy for peaceful purposes.

The President indicated that he is prepared to submit to the United States Congress, with every expectation of approval, plans which would encourage world-wide investigation into the most effective peace-time uses of fissionable material and which would begin to diminish the potential destructive power of the world's atomic stock-piles. Such plans should also demonstrate to peoples of all nations that the great Powers of the world, both of the East and of the West, are interested in human aspirations first and foremost, rather than in building up armaments of war; and they should open up a new channel for peaceful discussions and initiate at least a new approach to the many difficult problems that must be solved if the world is to shake off the inertia imposed by war and to progress towards peace. In his speech the President also revealed that since July 16, 1945, the United States have conducted forty-three atomic test explosions and said that atomic bombs to-day are more than twenty-five times as powerful as the weapons with which the atomic age dawned.

Trans-Atlantic Telephone Cable

An important step forward in the development of telephone communication between Great Britain and North America occurred on December 1, when an agreement was signed in London between the General Post Office, the American Telephone and Telegraph Co., the Canadian Overseas Telecommunication Corporation and the Eastern Telephone and Telegraph Co. of Canada, for the provision of the first trans-Atlantic telephone cable, as distinct from the existing telegraph cables. The installation, which is estimated to cost £12½ million, is likely to be ready in 1956 and will mark the completion of some twenty-five years of development in Britain and the United States. Two coaxial cables will be laid by H.M. Cable Ship *Monarch* from Oban in Scotland to Newfoundland, a distance of 2,250 miles, and these will be connected to a shorter section of coaxial cable from Newfoundland to Nova Scotia, about 360 miles in length. The former will be equipped with fifty one-way amplifying repeater units placed at 40-mile intervals, of an American type which has been adequately tested in deep water. A British type of two-way repeater will be incorporated in the single cable in Canadian waters, based on the experience of the British Post Office in the use of a similar cable during the past ten years between Anglesey and the Isle of Man, and for a shorter period between England and Holland and Denmark. When completed, the new cable should provide about twenty-nine telephone circuits between the United Kingdom and North America in place of, or in addition to, the twelve radio-telephone circuits, which are at times subject to deterioration or interruption due to fading and atmospheric disturbances. In addition, improved telegraph and telephone services to Australia and New Zealand will result from the direct wire connexion between London and Vancouver, from which point the radio service southwards is frequently superior to that across the Atlantic in the east–west direction.

Recording the Coronation: London–Montreal Joint Discussion by Radio

On December 3 the Institution of Electrical Engineers held a joint meeting with the Engineering Institute of Canada by means of a radio-telephone connexion between London and Montreal. After an exchange of greetings between the presidents of the two bodies, Mr. H. Bishop in London and Mr. R. L. Dobbin in Montreal, a paper entitled "Technical Arrangements for the Sound and Television Broadcasts of the Coronation Ceremonies on 2nd June, 1953", by W. S. Proctor, M. J. L. Pulling and F. Williams, was read in the Institution building in London. This paper described the many special and technical arrangements made for the largest outside broadcast ever undertaken by the British Broadcasting Corporation and the Post Office; the main details for broadcasting the Coronation by sound and television, and the special arrangements for getting pictures to North America, have already been summarized in *Nature* (171, 1050; 1953). A joint trans-Atlantic discussion followed the reading of the paper, in which Mr. J. E. Hayes, of the Canadian Broadcasting Corporation, and Dr. A. C. Don, Dean of Westminster, participated. After final remarks by the respective presidents on the success of the joint meeting, the technical discussions were continued independently in the two countries. In the lecture theatre in London, short extracts were shown of the B.B.C. telefilms of the actual crowning ceremony in Westminster Abbey. One of these was made by the suppressed frame system recently used by the B.B.C., while the other had been taken on the 'Mechau' camera installation, in which the vertical scanning process is effected by continuous motion of the film through the camera.

University of Nottingham

The Council of the University of Nottingham has accepted from Mr. C. T. Cripps, chairman and managing director of Pianoforte Supplies, Ltd., Simplex Works, Roade, Northampton, a gift of £100,000 for the endowment of two professorial chairs, a Cripps chair of metallurgy and a Cripps chair of production engineering. Pianoforte Supplies, Ltd., was founded by Mr. Cripps to produce components for the music industry. While still retaining the same trading title, the firm, under his guidance and direction, has progressed into full-scale production engineering, supplying numerous different industries with metal components in all kinds of finishes. The gift is the result of an appeal by the University to industry in the Midlands for support in its schemes for engineering studies and research. It is intended that an appointment to the Cripps chair of metallurgy should be made for the session beginning in October 1954, when a degree course in metallurgy will be instituted as had already been planned. The Senate had previously given approval in principle to a proposed degree course in production engineering, but the date from which the chair will be established will now be a matter for consideration by the University Council.

Dr. K. R. Ramanathan

In commemoration of the sixtieth birthday of Dr. K. R. Ramanathan, the February number of the *Proceedings of the Indian Academy of Sciences* (37, A, 167; 1953) contains a photograph of Dr. Ramanathan as frontispiece, an appreciation by Sir C. V. Raman, a bibliography of Dr. Ramanathan's scientific contributions, and seventeen papers mainly on meteorological subjects specially contributed by eminent meteorologists from India and other countries. Sir C. V. Raman gives a summary of Dr. Ramanathan's career and refers to the high position attained by him as a man of science, to his notable contributions in various fields of knowledge and to the leading part he has played in the development of an Indian school of meteorology. After a brief period as lecturer and research worker in physics, Dr. Ramanathan in 1925 became a government meteorologist and afterwards held posts as director of Agra Observatory, the Colaba and Alibag Observatories at Bombay, the Solar Physics Observatory at Kodaikanal, superintendent meteorologist at Poona and officer on special duty at Delhi. In February 1948, following his retirement from government service, he joined the physical research laboratory at Ahmedabad and is now actively engaged on investigations of the physics of the upper atmosphere. Dr. Ramanathan is a Foundation Fellow of the Indian Academy of Sciences and has served continuously for fifteen years as a member of its Council, in addition to being a vice-president during 1943–46. He was recently elected president of the International Meteorological Association. The selected list of Dr. Ramanathan's publications shows that his interests have covered terrestrial magnetism, seismology, meteorological optics and acoustics, but his outstanding contributions are in the field of study of the thermal structure and movements of the upper air. His earliest scientific paper was a letter in *Nature* (118, 337; 1926) dealing with the intensity and polarization of skylight at sunrise and sunset, and his latest, in the commemorative issue, deals with the height distribution of atmospheric ozone.

Materials available from the Radiochemical Centre, Amersham

The Radiochemical Centre, Amersham, Bucks, has prepared a new catalogue, entitled "Radioactive Materials", which describes the products of the Centre. The catalogue, which was first issued in connexion with the International Congress of Radiology held in Copenhagen during July 20–25, will be of interest to a wide range of users in the natural sciences, medicine and engineering. About six hundred radioactive appliances and compounds that are made at Amersham are listed, including a number of important materials which are new and have not previously been available in any country. They are dealt with under the separate headings of labelled compounds (carbon-14 and miscellaneous chemical compounds containing radioactive isotopes); processed radioisotopes, made by chemical separation from materials irradiated in a pile or cyclotron, or from fission products; natural radioelements; alpha and beta-ray appliances consisting of foils, plates and wires which incorporate a radioactive isotope; gamma-ray appliances containing radium for therapeutic purposes; gamma-ray sources for radiation standards or industrial radiography; and neutron sources. Among the labelled compounds of carbon-14, of which some eighty individual species can be supplied, there is now added a complete range of amino-acids which have been prepared by biological synthesis. Another new product of interest is the fission product, cæsium-137, which is likely to become important in industrial radiography, and particularly valuable for the radiotherapist is the revised list of radium appliances and the new beta-ray appliances, replacing radium plaques, for superficial therapy of the skin and of the cornea.

Clinical Research Board

The Medical Research Council announces that, in accordance with the recommendations in the White Paper on "Clinical Research in Relation to the National Health Service", a Clinical Research Board has been appointed after consultation, and in agreement, with the Ministry of Health and the Department of Health for Scotland. The Board has been appointed for a period of three years, with the following membership: Sir Geoffrey Jefferson, emeritus professor of neurosurgery, University of Manchester (*chairman*); Prof. Dugald Baird, Midwifery Department, University of Aberdeen; Sir Henry Cohen, Department of Medicine, University of Liverpool; Prof. E. C. Dodds, Courtauld Institute of Biochemistry, Middlesex Hospital, London; Sir James Learmonth, Department of Surgery, University of Edinburgh; Prof. A. J. Lewis, Institute of Psychiatry, Maudsley Hospital, London; Prof. G. W. Pickering, Medical Unit, St. Mary's Hospital, London; Prof. R. Platt, Department of Medicine, University of Manchester; Sir James Paterson Ross, Surgical Unit, St. Bartholomew's Hospital, London; Sir James Spence, Department of Child Health, King's College, Newcastle upon Tyne; Prof. B. W. Windeyer, Meyerstein Institute of Radiotherapy, Middlesex Hospital, London. The respective chief medical officers of the Ministry of Health, the Department of Health for Scotland, and the Ministry of Health and Local Government in Northern Ireland will be assessors to the Board, and the secretary of the Medical Research Council will attend all meetings. Dr. F. J. C. Herrald, a senior medical officer on the Council's headquarters staff, will act as secretary of the Board.

Inventions and Designs (Crown Use) Bill

The Inventions and Designs (Crown Use) Bill, the second reading of which in the House of Lords was moved by Lord Mancroft on December 1, purports embody in permanent legislation certain emergency powers in regard to the use of inventions and designs which are not patented or registered, and to compel the disclosure of information about them which the Government now possesses under the Defence Regulations. The first clause lists the specified purposes for which the use of inventions or designs may be authorized, including the supply of goods for defence purposes outside the United Kingdom, and the production of drugs, medicines or appliances for the Ministry of Health. The second clause enables a government department to authorize the use, for the services of the Crown, of any unpatented invention or unregistered design or any information relating to , and to reproduce any model or document, notwithstanding copyright, for that purpose, and to override any agreement regulating its use, subject to compensation from the government department giving the authority.

Although Lord Mancroft claimed that the Bill only retained essential powers and terminated others which were not required, strong objection to the Bill was raised in the debate, and especially to the third clause, which empowers the Ministry of Supply and the Admiralty to call for the disclosure of information relating to any invention or design, whether or not patented or registered, if it appears to be necessary for defence purposes. Lord Mancroft said that the Government recognizes that this is an extreme power to be used very sparingly, but the power was challenged in the debate as a substantial invasion of the liberties of the subject, and as likely both to violate the sanctity of commercial contracts and to have effects on arrangements for the exchange of technical information with overseas firms which would be very detrimental to the interests of Great Britain. Lord Woolton, in replying for the Government, admitted that consultations with industry are still incomplete and, acceding to the pleas of Lord Wilmot, Lord Balfour of Inchrye, Viscount Simon, Lord Silkin and others, moved the adjournment of the debate.

Florida State University

The State University of Florida has recently published under the ægis of its Research Council the ninth in its series of research studies. These studies were begun in 1950, and, since that time, separate volumes have been published dealing with the University's contribution to the natural sciences, the social sciences, modern languages and literature, history and political science, English and American literature, literature and philosophy, papers from the Oceanographic Institute, and, the most recent, developments in education. The latter includes a study of the Abbé Grégoire and his contribution to education at the time of the French Revolution, the growth of education in Florida during 1821–45 before it became a State, the relation of schools to local and national administration, the problems of junior high-school children, and the use of the cattle industry in Florida as an educational medium for children.

Royal Society : Election of Officers

The following have been elected officers and Council of the Royal Society for the ensuing year : *President*, Dr. E. D. Adrian ; *Treasurer and Vice-President*, Sir Thomas Merton ; *Secretaries and Vice-Presidents*, Sir Edward Salisbury and Sir David Brunt ; *Foreign Secretary*, Sir Cyril Hinshelwood : *Other Members of Council*, Dr. F. P. Bowden, Prof. F. Dickens, Prof. H. J. Emeléus, Mr. A. E. Ingham, Dr. G. M. Lees, Prof. E. G. T. Liddell, Prof. R. A. McCance, Prof. P. B. Medawar, Sir Edward Mellanby, Prof. P. B. Moon, Prof. W. H. Pearsall, Prof. R. O. Kedman, Prof. Alexander Robertson, Dr. C. Sykes, Prof. G. Temple and Prof. C. M. Yonge.

Announcements

Mr. H. Bondi, Fellow of Trinity College, Cambridge, has been appointed to the University of London chair of mathematics tenable at King's College, in succession to Prof. G. Temple, now Sedleian professor of natural philosophy in the University of Oxford (see *Nature*, 171, 911 ; 1953).

The Minister of Supply has appointed Dr. R Cockburn, scientific adviser to the Air Ministry, to be the principal director of scientific research (guided weapons and electronics), and Mr. J. E. Serby, deputy director of the Royal Aircraft Establishment, Farnborough, to be director-general of guided weapons.

The Chemical Engineering Group and the Food Group of the Society of Chemical Industry are arranging a conference on "Chemical Engineering in the Food Industry", to be held at the Wellcome Research Institution, 183–193 Euston Road, London, N.W.1, during March 18–19, 1954. Further information can be obtained from the Assistant Secretary, Society of Chemical Industry, 56 Victoria Street, London, S.W.1.

The third congress of the International Association of Gerontology will be held in London during July 19–23, 1954. The meetings and discussions will be divided between three main sections : biology and pathology ; geriatric medicine and psychiatry ; and sociology and psychology. Following the congress a number of tours will be arranged to study the care of the elderly in various parts of Britain. Further details can be obtained from the British organizing secretary, Mrs. A. Humphrage, B.M.A. House South, Tavistock Square, London, W.C.1.

The Swedish Academy of Sciences has issued two supplementary parts to the "Bibliography of J. J. Berzelius", edited by Arne Holmberg, the first dealing with printed works by or about Berzelius, and the second with manuscripts ("Bibliografi over J. J. Berzelius", second supplement, parts 1 and 2. Stockholm : Svenska Vetenskapsakademien, 1953). These include some items which have come to light since the earlier publications and also references to recent works in which statements about Berzelius appear. These supplements are indispensable to those possessing the former publications.

The Pacific Science Council Secretariat has compiled for the Pacific Science Association a booklet which lists the "Organizations engaged in Scientific Research on an International Scale in the Pacific" (pp. 32 ; from the Association, Honolulu ; 1953). Besides the address, scope of membership and publications of the organizations listed, the booklet gives their objectives and, for some of them, lists the projects on which they are engaged. There are also charts showing the organization and interrelations of the various government and non-government agencies concerned, including the Specialized Agencies of the United Nations, but the projects of these Agencies are not elaborated. Besides the islands of the inner Pacific, the Pacific rim territory is covered, but national and local agencies are not listed.

HEALTH, WELFARE AND EFFICIENCY OF THE WORKER

THE first conference of the British Occupational Hygiene Society was held at the London School of Hygiene and Tropical Medicine on November 2. The conference was opened by the Minister of Labour and National Service, Sir Walter Monckton, who said that provision for occupational health in the widest sense is increasingly concerning the Government. The human element in industry is vital for productivity and, while the primary aim of industrial research is understandably concerned with discovering new and improved methods of production, it must not overlook hygiene and safety factors. The Society, continued Sir Walter, has valuable work to do in bringing together the physician, the medical scientist and the psychologist, who study man, and the physical scientist, chemist and engineer, who study his environment.

In his presidential address, Dr. T. Bedford outlined the development of occupational hygiene in Great Britain, which has grown from a wish to protect young persons and women from the evils of gross overwork some one hundred and fifty years ago. Safety and concern with industrial poisoning date back about ninety years, and the progress made is due to the initiative and devotion of the Factory Inspectorate. It was not until the First World War that concern with productivity, vital for success, resulted in the formation of the Health of Munition Workers Committee, on behalf of which many investigations were undertaken. Since then, various government establishments have worked in the field, and some university departments have also been interested. Further impetus resulted from the Second World War, both in connexion with war industries and with the fighting services.

Dr. Bedford said that occupational hygiene deals with the prevention of disease due to industrial materials and also with the effects of the working environment. The application of physiological and anatomical principles to the design of machines, the arrangement of industrial tasks and psychological factors, such as fatigue and maladjustment of the worker to his vocation or working group, are likewise included. It is to be hoped that the Society will make contributions to all these fields of knowledge.

There are grave deficiencies in the postgraduate medical training available in Britain for medical practitioners who wish to work in industry, and the instruction in methods of measuring and controlling the worker's environment is inadequate. No university in Britain offers a full course for engineers and other non-medical graduates on the lines of those which have been so successful in the United States. This seemed to Dr. Bedford to be a serious lack.

Mr. S. A. Roach, of the Medical Research Council's Pneumoconiosis Research Unit, gave a paper on "Measuring the Worker's Environment", which dealt with pneumoconiosis in the coal industry that is caused by the inhalation of coal dust over a long period. The quantity of dust inhaled is expressed in particle-years per c.c. (sizes between 0·5 and 5 microns), and Mr. Roach claimed that, when this figure was less than 4,000, no X-ray abnormalities were detectable in the sixty colliers who were examined. Fifty per cent abnormalities occurred at more than 24,000 particle-years per c.c.

Dr. D. G. Harvey, of the Medical Research Council' Department for Research in Industrial Medicine, the gave his paper on "Problems of Chemical Toxicity" Pointing out that environmental studies in a chemica industry are often not made until after an acciden has occurred, Dr. Harvey made a plea for the investigation of toxic risks before a new substance is use in production. In the determination of atmospheri concentrations, it is not enough to take a few 'grab samples; mass concentration values over a good length of time, say, one day or a working shift, are essential. Routine determinations of blood and urin levels of a toxic substance give indications of the minimum amount present in the body and are useful for monitoring workers. The elimination-rate can also be found from these observations by removing a man from exposure.

Animal experiments are valuable, continued Dr Harvey, because, by administering repeated small doses, accumulation in the body can be demonstrated; substances which act like this are particularly dangerous to human beings exposed to chronic intoxication. Quantitative biochemical species differentiation has to be watched for, however for man is notably inefficient in detoxicating poisons Thus, initial blood-levels of 60–80 μgm. of 3:5-dinitro-*o*-cresol per gm. are reduced to insignificant amounts in two days in the rabbit, eight days in the rat but forty days in man.

The final speaker was Mr. J. S. Braham, engineering controller of Imperial Chemical Industries, Ltd., who pointed out that, with the industrial capital investment in Great Britain now exceeding £1,000 million a year, the industrial designer is faced with many and complex problems. The potential savings in capital and production cost to be derived from good design are considerable, and the creation of a new plant or factory is a matter for many people who represent the various technical and commercial interests involved. Outlining the principal stages in the growth of a project, Mr. Braham emphasized that the requirements of hygiene ought to be considered in each to some degree and, at certain crucial stages, very closely. Those who are responsible for hygiene cannot be in touch with research, development and design too early. This early contact is very important because hygiene is not a primary consideration of scientific workers engaged in creating a new manufacturing process.

The ensuring of the necessary close co-operation between the industrial hygienist and the designer is a problem of organization and of procedures calculated to bring all the relevant factors under the notice of the proper people at the proper time. This Mr. Braham proposed to facilitate by preparing a special list of all issues of hygiene for routine use as an *aide-memoire*. He also suggested the keeping of a record or history sheet for a project on which would be detailed the consultation of all interests and the implementation of the decisions taken.

Mr. Braham thought that working conditions in British factories are steadily being improved, though some remaining black spots have to be removed. The provision of healthy, safe and agreeable conditions for those who work in them is a moral obligation; it is also an economic necessity for maximum productivity upon which the prosperity of all depend.

The conference will be reported in full in the January issue of the *British Journal of Industrial Medicine*. The Society is arranging another conference at the London School of Hygiene and Tropical Medicine, on April 6, 1954, when the subject will be on the maximum allowable concentrations of toxic and dangerous air contaminants.

C. N. Davies

INTERNATIONAL SCIENTIFIC FILM ASSOCIATION

ANNUAL CONGRESS IN LONDON

The seventh annual congress of the International Scientific Film Association was held during September 18–26 in London on the South Bank, the meetings of the general assembly and specialized groups being in the Royal Festival Hall and the afternoon and evening scientific film shows being in the National Film Theatre. More than one hundred delegates and observers from twenty-two countries and from international bodies (such as Unesco) attended, together with a large number of visitors. At the various sessions more than two hundred and twenty films were shown from twenty-four countries, including some seventy medical films. During the congress Canada and Morocco were made members of the Association.

The congress was opened at the gala première film show on the evening of September 18 by Sir Walter Monckton, Minister of Labour and National Service, who paid tribute to the Scientific Film Association of Great Britain for its work in organizing the congress and for its services to industry generally. The films shown at this performance included contributions from India ("National Physical Laboratory"), Great Britain ("The Desert Locust"; World Wide Pictures, Ltd.), Hungary ("Blossom Time till Autumn Frost"; a remarkable Nature film by Homoki-Nagy), Australia ("Pre-stressed Concrete Tower"), Canada ("Embryonic Development—the Chick"; J. V. Durden), Belgium ("Combat avec l'Ombre"), U.S.S.R. ("Life in the Arctic"; Moscow Popular Science Film Studio, directed by A. Zguridi) and France ("Flammes du Soleil"; Paris Observatory, produced by Jean Painlevé and directed by Joseph Leclerc).

The next day the general assembly met, appointed working committees and transacted the internal business of the Association, adopting the honorary secretary's report and the balance sheet. The congress then divided into its various specialized groups which held meetings during the following six days.

The Research Group held four meetings, two of which were jointly with the Medical and Industrial Groups, respectively. Its first meeting was on the morning of September 20, when three films of research interest were shown and discussed. The first, "Growth of Crystals" (France; Jean Dragesco), used time-lapse and polarized-light techniques to study the crystallization of various stable and unstable substances. The second, "Waters of Coweeta" (United States), was an impressive record of forestry research based on the long-term analysis and measurement of the run-off from watersheds under different conditions. The third, "Biology of the Hamster" (Western Germany; Dr. Gotthard Wolf), was part of a German plan to make an encyclopaedia of film and was a complete record of one animal's behaviour during a typical chain of circumstances.

The second research session, jointly with the Industrial Group, was on September 22, when the main subject was "High Speed Films in Industrial Research". There were five contributions—two French and three British. M. Galey, of the Institut de Rechèrches de la Sidérurgie, showed a film used for investigating the interior of a Martin furnace; it was interesting to compare this with the British contribution by Mr. C. Burns (British Iron and Steel Research Association), who showed a three-dimensional film made to investigate the movements of air and coke particles inside a blast furnace. The technique used enabled actual measurements of high accuracy to be made of the size and shape of the cavity caused by the air blast, and provided a good example of the way films can be used to investigate subjects which cannot be explored by other methods. Mr. John Rogers (Building Research Station) read a paper, illustrated by film, on the uses of the film in building research, which included an interesting description of the use of films in investigating problems of fluid flow. There were a French and a British contribution illustrating railway research: M. Censier, chief of the cinema service of the French national railways, introduced a film showing the use of the high-speed camera on the French railways to investigate speed and wear tests; and Mr. J. C. Lucas (Railway Executive Research Department) showed a film made to investigate a condition of rail wear on electric tracks known as 'periodic side-cutting'.

The third session, on September 23, with Dr. G. Wolf presiding, was a joint meeting with the Medical Group to discuss image converter techniques. Papers were read by Dr. J. S. Courtney-Pratt (University of Cambridge) on the use of image converter tubes in high-speed photography, Mr. A. E. Sarson (Marconi, Ltd.) on the application of television to cinematography and Dr. W. J. Oosterkamp (Philips, Netherlands) on a new X-ray intensifier.

The final research session was on September 26, at the Shell Film Unit, under the chairmanship of Dr. J. Frédéric (Belgium). Ten films were shown and—very briefly—discussed. They included M. R. G. Busnel (France) introducing a film "Enregistrements par une technique electro-accoustique de movements de faible amplitude : applications à la physiologie et la pharmaco-dynamie", which depicted the measurement of small pulsations (beating of a frog's heart, blood vessels in a mouse's foot, etc.) by an apparatus devised by Busnel and Pasquinelly, and amplified and recorded by an oscillograph. Dr. Frédéric showed his film "Recherche expérimentale de Chondriome", investigating and recording movements of mitochrondria when treated with various reagents. Dr. W. Rogers (East Malling) presented "The Freezing of Plant Tissues", which attracted great interest and applause.

Other events during the congress were a well-planned series of industrial sessions, covering the use of films on vocational guidance, training of personnel, motion study and industrial welfare; a conference on the dissemination of science by television, under the chairmanship of Mrs. Mary Adams; a morning session on education addressed by Dr. J. Harrison (Educational Foundation for Visual Aids) and Dr.

H. D. Turner (Extra-mural Department, University of Sheffield); and a session on stereoscopy with Prof. W. D. Wright (Imperial College of Science and Technology, London) in the chair.

During the congress, the general assembly resolved to approach the International Federation of Film Archives to secure international co-operation in the preservation of films relevant to the history of science and technology, and also decided to urge its constituent national organizations to approach their respective governments with proposals for facilitating the interchange of scientific films between different countries.

At the concluding session of the assembly, held on September 26, the officers of the Association for 1953–54 were elected as follows: *President*, Jean Painlevé (France); *Vice-Presidents*, Jan Korngold (Poland) and Prof. Mario Ponzo (Italy); *Honorary Treasurer*, J. W. Varossieau (Netherlands); and *Honorary Secretary*, John Maddison (Great Britain). Sir Arthur Elton, leading the British delegation, paid a warm tribute to the retiring president, John Maddison, for his five years of service in that office.

The eighth annual congress of the Association will be held in Rome during October 1954.

J. Stewart Cook

THE CHILDREN'S FILM FOUNDATION

The Children's Film Foundation was set up in 1951 with the object of "ensuring the production, distribution and exhibition of special entertainment films for children". The Foundation does not make its own films, but from its own selected programmes it offers each film to those production companies competent to deal with the themes involved. The chosen company then produces the film for a fixed fee and under the supervision of the Foundation. So far, nineteen different companies have produced films for the Foundation.

The Foundation is a non-profit-making organization financed from the British Film Production Fund, Ltd. Its directors are nominated by the British film trade associations, which also elect an independent chairman. Miss Mary Field, the well-known pioneer in children's and Nature films, is the executive officer; and Mr. W. G. R. Thom is secretary and business manager.

Cinemas which organize children's clubs and matinees have agreed to exhibit the Foundation's films in rotation, and five complete programmes are now circulating in Great Britain.

The films so far completed include eight features (one hour each), eight short stories (twenty minutes), eight "Our Magazine" (ten minutes), one novelty (ten minutes), and four pen pictures (ten minutes)—a splendid record for two to three years of work.

The most recent programme of the Foundation's films was presented at the Odeon Cinema, Kensington, London (by permission of the J. Arthur Rank Organization), on December 12 before a packed audience of children which was also graced by the presence of H.R.H. Princess Alice and many local dignitaries. The programme, which lasted two hours altogether, was preceded by an episode of a serial and a cartoon. Then followed one each of the Foundation's latest pen picture, comedy and feature films.

The pen picture is included in these programmes to conform to the Foundation's policy of producing a balanced programme and so including one or more films suitable for children less than nine years of age. The one shown, "A Letter from Wales", took the form of a pictorial letter written by a village boy to a relative abroad. It was obvious that the young audience was intensely interested and were, perhaps subconsciously, learning some human geography. The comedy, "A Good Pull-up", was good fun.

The feature film, "The Secret Cave", was excellent from all points of view. The play was based on Thomas Hardy's "Our Exploits at West Poley". So far as is known, this is the only story Hardy deliberately addressed to juvenile readers. It was commissioned by an American magazine in 1883, but never published. The manuscript remained in the United States and was rediscovered in 1951, when it was published in Britain. For the purpose of the film the scenes are set on and under the Mendip Hills in Somerset. The underground scenes were made in the famous Wookey Hole Caves. There can be nothing but praise for this excellent children's film from the points of view of open entertainment and subtle teaching. The children followed an exciting story while revelling in the beautiful Mendip scenery, glimpses of Somerset life and the thrill of underground caverns. (The film writer, Mr. J. Mendoza, might have slipped in a verbal picture of the Glastonbury Thorn and the earliest days of Christianity in Britain when one of his juvenile characters is pointing out a very characteristic view of Glastonbury Tor across the Somersetshire plain.)

These three films revealed what excellent work the Children's Film Foundation is doing not only in juvenile entertainment but also in education and training. We came away somewhat confused, however, because each film immediately followed the one shown previously. It occurred to us that if this is the usual practice at children's film matinees then young audiences probably miss some points through such confusion. We know that a crowd of children is impatient when waiting for their entertainment and frequently show their impatience in no uncertain way; but we suggest that a period of three to five minutes might be allowed to elapse between one film and the next. The interval could be filled by some properly organized community singing which the Foundation might consider fostering in the form of very short films of folk songs and traditional and national airs. The words and music could appear on the screen (with an appropriate scenic background—still or moving), and the audience conducted by some form of pointer such as a bouncing white ball passing along the lines of words. From a collection of such community-singing films, those organizing a children's matinee could select the most appropriate song. For example, "The Secret Cave" could have been preceded by "A Farmer's Boy", and "A Letter from Wales" by "Men of Harlech" or "Land of my Fathers".

So far as the films are concerned, we must say that if all films witnessed by children were of the same excellent entertainment and teaching value and of the same artistic merit as those of the Children's Film Foundation, then we should soon begin to hear less about the cinema being one of the contributory causes of juvenile delinquency and more of its considerable value as a visual aid.

Details of the objectives and organization of the Children's Film Foundation can be obtained from Mr. W. G. R. Thom, Children's Film Foundation, Ltd., 73 Newman Street, London, W.1.

REGISTRAR GENERAL'S STATISTICAL REVIEWS OF ENGLAND AND WALES

THE "Medical Text" volume of the "Registrar General's Statistical Review of England and Wales for the two years 1948–49"[*] is presented in its usual form and provides a commentary on the figures already published in Part 1 of the "Review" for these years. Points of general interest concern the general death-rate, infant mortality, tuberculosis and cancer. The civilian crude death-rate reached a record low level of 11·0 per 1,000 in 1948 (it rose to 11·8 per 1,000 in 1949), partly because of the unusually low rates recorded in the first two quarters of the year. This in turn was due to the remarkable absence of influenza during those quarters. An extensive discussion of the trend of the infant mortality-rates during the past forty-four years shows that the long-term tendency for rates of mortality in the later parts of the first year of life to improve more rapidly than the neo-natal rates has continued. Regional disparities have remained remarkably constant; Greater London showed a greater improvement in 1949 over 1938 than did the North of England and Wales. The greater decline in Greater London was shown in the 'postnatal' rates only, the improvement in the neo-natal rate being very uniform as between the various regions. It is also demonstrated that the social class differential in the infant mortality-rate widened between 1939 and 1949. The postnatal rate for unskilled occupations was 3·8 times as high as the rate for professional occupations in 1939, and 4·4 times as high in 1949. The regional and social class differentials are, of course, closely interconnected. Mortality from tuberculosis began to decline rapidly in 1948. The figures for 1948 and 1949 show a marked shift in the age distribution of mortality from respiratory diseases among males. There was, in fact, an increase in mortality among males aged sixty-five and over in contrast to the great decline at the age range of fifteen to fifty-four. No such shift is shown in female mortality from this cause. The crude death-rate from cancer continued to rise in 1948 and 1949, but the downward trend among women aged thirty-five to seventy-four continued. The contribution of cancer of the lung to the increase in male cancer mortality is discussed. The 'lung' rate among males rose from 866 per million living in the age-range fifty-five to sixty-four during 1940–44 to 1,637 per million in 1949. The extent to which changes in diagnosis may have contributed to the apparent increase in the incidence of cancer of the lung is somewhat inconclusively discussed.

The "Medical Tables" volume, Part 1, for 1951[†] shows a rise in the crude death-rate to 12·5 per 1,000, partly as a result of the influenza epidemic in the first quarter. Influenza directly caused more deaths than did tuberculosis in this year. The decline in mortality from tuberculosis continued. The number of deaths from this cause in 1951 was 40 per cent lower than that in 1949. The number of deaths from cancer again increased, and accounted for 16 per cent of all deaths in the year.

AMERICAN ACADEMIC FREEDOM IN 1953

DESPITE widespread belief to the contrary, Prof. Preston Slosson thinks that the average American professor is one of the freest individuals in the world (*Univ. Rev.*, 26, No. 1; October 1953).

There are four levels on which the American professor is open to attack: the Federal Government, the State Government, the administrative authorities of his own institution and 'pressure groups' with no official status.

The immense publicity attending certain recent investigations by Congressional committees has attracted most attention to the Federal Government, although the actual threat to freedom is least from this source. Congress, like most legislative bodies, has the right to conduct inquiries and investigations into almost any matter which might conceivably become a subject of eventual legislation. This power, in itself, is salutary and useful. Unfortunately, committee investigations have not been surrounded with the legal protections which have been developed for court trials, and questions can be asked at random, no matter how irrelevant or full of false implication. Yet, except for the effect on the professor's reputation, the congressional committee has no power to penalize.

At the State-level, there is quite a variety of educational institutions controlled by State laws and State officials; these include State universities.

The chief power of the State legislature is the power of the purse. The power of rule is almost always in the hands of a board of regents, or a similar body, chosen by appointment or by election to represent the State. Most of them are business or professional men who delegate the details of management to a president, who heads the entire university, and to deans, who head individual colleges or schools within it. The president and the deans, in turn, consult the faculty committees. If the regents are not satisfied with the way things are going, they can change presidents. Full professors, and usually associate professors, have "tenure", that is, contracts guaranteeing permanent employment; younger men are employed for periods of a year or more at a time. Even a professor with tenure can be removed for "sufficient cause" after "due process".

Private colleges and universities are managed in much the same way, except that they are governed by boards of trustees, elected by the alumni, instead of by State-chosen officials. Except for a few academic tragedies of a purely personal sort, there would be few cases of heresy hunting were it not for clamour from angry alumni, parents, taxpayers, and organized pressure groups.

This fourth level is therefore the significant one. Popular clamour has, in times past, been directed at many targets. The only peculiarity of the present situation is that most of the intolerance runs in the single direction of Communists and their alleged sympathizers. Yet in California, where many professors were dismissed for refusing to take a special anti-Communist oath, the State courts ultimately vindicated their stand and held that the requirement was unlawful. The American Association of University Professors has noted no significant increase in the number of professors removed from their posts in recent years, although a few such cases do occur.

A RELATIONSHIP BETWEEN DOMINANCE, PHENOTYPIC STABILITY AND VARIABILITY, AND A THEORY OF ALTERNATIVE GENETIC PATHWAYS

By Dr. D. LEWIS

John Innes Horticultural Institution, Bayfordbury, Hertford, Herts

THE response of an organism to its environment is a problem which has been thought of mainly in terms of the fitness of different genotypes to different conditions. The emphasis has been on the fitness of a heterogeneous population to environmental changes and not so much on the individual's reaction to change. Recently it has been shown in several organisms that the amount of reaction to change, or *variability* within an individual or within a homogenic line, due to non-genetic causes—and therefore due to environment—is gene controlled. This has been shown by comparing variances or suitable functions of the variances of individuals or lines of F_1 generations with their parents grown in one controlled environment. In some species the F_1 was less variable than the parents, and in others, of equal or greater variability. These results are summarized in Table 1.

Table 1. Species examined for F_1 Variability relative to the Parental Lines

	F_1	Ref.

Primula sinensis and the *Drosophila* species are outbreeders while *Hordeum* and *Galeopsis* are inbreeders, and this leads Dobzhansky and Wallace[4] to suggest that the difference in the F_1 variability was due to the different genetic balance attained in outbreeders and inbreeders.

In *Zea mays*[7], an outbreeder, several different characters were examined and it was found that the hybrids could be more, or less, variable than the inbred lines according to the character measured.

A slightly different approach to the problem was started in 1948 by raising plants of *Lycopersicon esculentum* in two different environments and determining the effect of the environment on the mean of the character, the average dominance, and variability. The results from these experiments appear to throw some light on the seemingly conflicting results reported in other organisms, and can be explained in terms of gene action with a theory of alternative genetic pathways. This theory in its simplest form assumes that when different alleles are both operating in a heterozygote each allele may operate through a similar but slightly different synthetic pathway. Each pathway will tend to have its own optimum of environmental condition for operation.

In *Lycopersicon* the character measured was the number of flowers, and the two environments were $H.E. = 13°$ C. and $L.E. = 26°$ C., maintained during th first few weeks of growth. The $H.E.$ has the effec of increasing the number of flowers by a factor o about 1·7 in the pure lines[8]. Two parental pur lines differing in flower number and derivativ generations have been compared in the two environments. As a measure of the phenotypic change du to the difference between the two environments, a *stability factor*, $\frac{(\text{mean in } H.E.)}{(\text{mean in } L.E.)}$, was used. As a measure of variability due to "intangible environmental effects produced by developmental accident or uncontrolled non-genetic variation"[9], the varianc or a suitable function of the variance calculated from lines grown in one environment has been used. In a comparison between an F_1 generation and it parents is being made, the term *relative variability* has been adopted which is denoted by

$$\frac{2F_1 f(v)}{f(v)(P_1 + P_2)}$$

$f(v)$ = suitable function of variance, v

Some of the results of the experiments can be summarized as follows:

1. The dominance, or more strictly speaking average dominance since we are dealing with a polygenic character, is changed by the environment: low flower number being dominant in the $H.E.$, and intermediate in the $L.E.$

2. The F_1 is more phenotypically stable than the two parents in relation to the two environments. This is caused by the change to dominance by an environment which is having the opposite effect on the character to that of the gene. For example, low number is dominant only in the high expression ($H.E.$) environment. A theoretical model shows that the F_1 need not necessarily be more stable than the parents; for example, when the high number of flowers is dominant only in the $H.E.$, the F_1 would be less stable than the parents.

3. The relative variability of the F_1, as measured in one environment, is related to the degree of dominance operating with the particular environment and genetic situation. Complete lack of dominance results in low F_1 relative variability: dominance is accompanied by a high F_1 relative variability, which can, in some cases, be higher than the parents.

A search for data in the literature suitable for an analysis into relative variability and dominance has revealed figures for plant-height and leaf-length in *Nicotiana rustica*[10].

Relative variabilities and dominance values based on Wigan's[11] formula have been plotted for the *Nicotiana* and *Lycopersicon* data in Fig. 1.

The dominance is represented along the horizontal axis: a value of 0·5 represents complete lack of dominance, a value of 0·0 represents complete dominance of the larger, and 1·0 complete dominance of the smaller, character expression. The *Nicotiana* data supply the left arms of the V graph, the *Lycopersicon* data represent the right arm. It should be pointed out that the points representing the *Lycopersicon* data are from populations of one hybrid and pair of parents but from different treatments or parts of the plant, while the *Nicotiana* data are from different hybrids and parents all grown under the same environment.

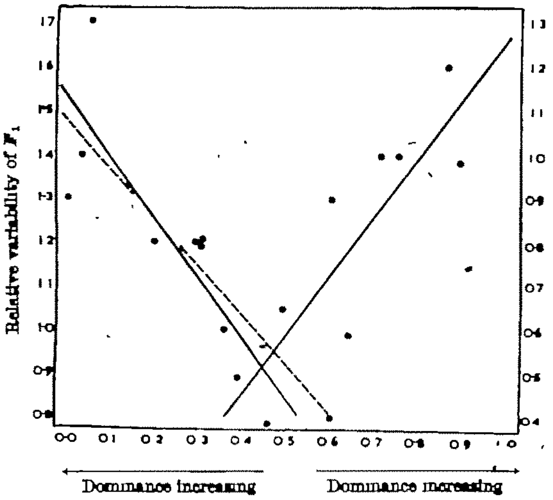

Fig. 1. Relationship between dominance and F_1 relative variability. Note that absence of dominance, with a value of 0·5, gives the lowest relative variability; as the degree of dominance increases so does the relative variability. The right-hand arm of the graph and the Φ points represent flower number data from *Lycopersicon*; the two left-hand arms represent data from *Nicotiana*, ●, ——— = plant-height, O - - - = leaf-length. Lines are based on regression coefficients

It is clear from the graph that the lowest F_1 variability is obtained with the minimum of dominance; and the good agreement in two species suggests that this relationship may be generally applicable.

A re-examination from this aspect of the published examples which are not suitable for graphical representation supports this view. Thus the *Galeopsis* and *Hordeum* hybrids exhibit dominance and high F_1 variability. In an interspecific hybrid in *Petunia*[11] the F_1 is intermediate with no dominance and is less variable than the parents.

The relationship between heterosis and F_1 variability is another aspect of the problem, but at present there are too few data to allow of a generalization. In *Lycopersicon*, certain hybrids obtained from F_4 selections for flower number showed negative heterosis and high F_1 variability. Certain hybrids in *Galeopsis*[4] showed positive heterosis and high F_1 variability. If in these cases heterosis was due to favourable dominant genes, then the high F_1 variability is in agreement with the dominance-variability relationship. Other types of heterosis involving balanced heterozygosity probably occur, and these may be expected to show a different relationship.

The relationships found between dominance and F_1 variability, and between change of dominance and phenotypic stability, are given a certain unity by the theory of alternative genetic pathways. It is assumed that when an allele is completely recessive, it is not in operation. Thus the maximum number of alternative pathways will be in a heterozygote which does not show dominance. The high number of different pathways with their different optima will tend to damp the effect of environment and result in a lower non-genetic variability. The change of dominance due to big environmental differences can be explained on the opening or closing of certain pathways by the environment. The particular pathway affected by an environment will determine the phenotypic stability to the environmental difference being tested.

Another model for such a theory has been provided in the antigenic system in *Paramecium*[13], in which genes come into operation under different conditions. The similarity between the alternative genetic pathway concept and that of alternative biochemical syntheses of Hinshelwood[14] to account for adaptation in micro-organisms is obvious. The adaptation in micro-organisms, due to the switch-over to an alternative biochemical synthesis, should occur only when there is the alternative genetic pathway to carry it out. Alternative genetic pathways probably also influence ecological adaptation in higher organisms.

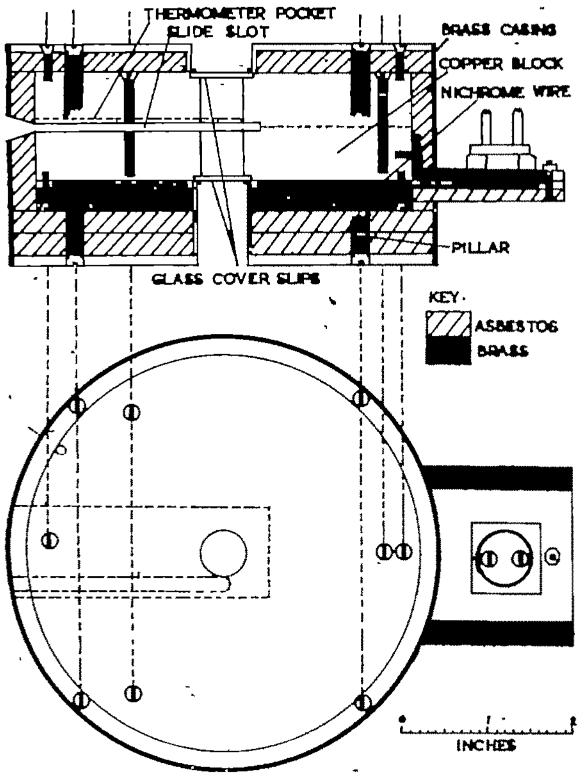
A HEATING INSTRUMENT FOR THE ACCURATE DETERMINATION OF MESOMORPHIC AND POLYMORPHIC TRANSITION TEMPERATURES

By Dr. G. W. GRAY
University College, Hull

TEMPERATURES for the transitions of solid to smectic or nematic, smectic to nematic, and smectic or nematic to isotropic may be obtained in a melting-point capillary in a well-stirred paraffin bath, because of differences in the appearance and behaviour of these states. The solid and the isotropic liquid are readily distinguished from the smectic state, which appears as viscous, opaque droplets adhering to the capillary walls, and from the nematic state, which is also opaque, but mobile and fluid. The smectic–nematic change may therefore be taken as the temperature at which the viscous smectic state coalesces and flows to a cloudy melt. However, erroneous results were obtained in the case of certain 4-*n*-alkyloxy-4′-carboxy-diphenyls, the smectic and nematic states of which interchange at high temperatures (240–260°). At these temperatures, the viscosity of the smectic state decreases to such an extent that flowing occurs before the sample assumes nematic properties. Moreover, the capillary method is subject to error, since abrasions in the glass and the amount of material may affect the ease of flow. Furthermore, polymorphic transitions pass unnoticed in a melting-point capillary.

The need arose for a means of heating samples at easily and carefully controlled temperatures, while observing the material under a microscope. In this way, solid–solid changes will be visible, and the mesomorphic transitions will be seen as actual changes in the appearances[1] of the phases. Such an instrument, which was constructed in our work-



Microscope heating block

shops, is now described, and has been used for the accurate determination of the constants of a large number of mesomorphic substances. A plan and elevation of the instrument are shown.

To minimize temperature gradients in the block, high-conductivity copper was used. The block is approximately 4¼ in. in diameter and 1¼ in. thick, and consists of two parts which are bolted together. The ¼-in. diameter hole is covered above and below by glass cover slips, which are held in position by spring clips. These minimize air currents, which give localized cooling on the part of the slide examined under the microscope. When operating at high temperatures (above 200°), considerable sublimation occurs and makes the upper cover slip opaque. Since this cannot easily be removed for cleaning, the upper cover slip is replaced when high temperatures are used by an ordinary microscope slide, which lies over the hole, on top of the outer casing. As the slide becomes opaque, it is gradually pushed over to a clean part. This makes continuous observation easy even when rapid sublimation occurs. The slide slot is cut to allow easy insertion and removal of a slide, and the thermometer pocket is drilled so that the surface of the bulb is exposed to the air in the hole between the cover slips. The recorded temperature is therefore that of the sample mounted on the end of the slide, and not merely that of the copper beside the hole. Samples were mounted by melting between a glass slide and a cover slip, to obtain a thin film of the specimen.

The heater consists of 22 ft. of 36-gauge nichrome wire (diameter 0·0076 in.), with a resistance of approximately 250 ohms. The wire is wound on a circle of mica sheet (3¾ in. diameter), with a ¼-in. hole in the centre. Slightly larger mica sheets, of the same shape, are placed on either side, and the heater unit is secured against the underside of the block by two brass plates of the same pattern as the copper block to which they are bolted. The heater wires are led off from beneath the block to the plug, which is attached to an L-shaped brass plate bolted to the side of the block.

A brass outer case for the block was constructed. Two ¼-in. thick brass plates of approximately 5 in. diameter, with a ¾-in. hole in the centre, are supported 2¾ in. apart by four pillars of brass tubing to which the plates are bolted. The thin brass outer casing is bent around the circular plates and bolted to the pillars. The heating block is housed in this case, from which the plug mounting protrudes. Two brass tubes are let into the top and bottom of the casing and meet the copper block beside the spring clips which secure the glass covers. These tubes are soldered and brazed in position, and complete the outer jacket. Asbestos board, two ¼-in. layers below and one ¼-in. layer above, and asbestos cement around the sides insulate the copper block. The upper plate of the case is securely bolted through the upper insulation to the top of the copper block.

The instrument is mounted on the rotating stage of a Baker polarizing microscope. The supporting bracket of this instrument has been cut and a 4½-in. brass column inserted to raise the barrel and focusing arrangement well above the stage. Using a 1½-in. objective there is a clearance of 0·6 in. between it and the insulated top of the casing.

A variable resistance of 350 ohms in the external circuit controls the rate of heating, as shown by the figures in the accompanying table.

Resistance in external circuit (Ω)	Temperature at (min.)				Rate of temp. rise (degrees per min.)	
	0	60	120	180	First 30 min.	Last 30 min.
0	9°	320°	—	—	7·2°	3·2°
100	10°	194°	248°	268°	4·0°	0·18°
200	10°	135°	174°	192°	2·7°	0·1°
300	12°	89°	123°	136°	1·6°	0·1°
400	17°	74°	96°	106°	1·3°	0·1°
500	20°	57°	76°	85°	0·8°	0·07°

The accuracy of the instrument was determined by taking melting points of purified organic compounds covering a range of temperature from 40° to 360°. The melting points were also determined in the usual way. The corrected values, by the two methods, agreed within ± 0·25 deg., provided that the optimum rate of heating in the region of the melting point was 2 deg./min.

The design of the instrument, with a slide slot in the side, has the advantage that there is a slight temperature gradient across the specimen. Melting begins at the side, away from the slot opening, and passes quickly, but as a well-defined wave front, across the field of vision. This is valuable in the determination of certain transitions which would be difficult to detect if they occurred uniformly over the sample.

Mesomorphic and polymorphic transitions were determined in the following way. The slide was inserted in the heating block and the temperature raised fairly rapidly (5 deg./min.) to obtain the approximate solid–solid transition temperatures. The block was allowed to cool until the stable solid reappeared and the measurements repeated, using a rate of heating of 2 deg./min., from 10 deg. below the transition point and until each transition had occurred. The mesomorphic transitions were, of course, indicated by the ordinary melting-point determinations. The temperature was therefore raised quickly to within 10 deg. of each value, and then controlled, using a suitable resistance in the external circuit, to a rate of increase of 2 deg./min. The transitions were seen as a wave front, and the phase type identified as smectic, nematic, or cholesteric by its appearance[1], which was always well defined in polarized light. The transition to the isotropic liquid occurred when the field of vision became extinct in polarized light. [Aug. 17.

TOXIC FLUORINE COMPOUNDS

By Dr. F. L. M. PATTISON

Department of Chemistry, University of Western Ontario,
London, Canada

MONOFLUOROACETIC acid and its derivatives have received widespread attention during and since the Second World War, because of their interesting and varied pharmacological effects on different species of animals. From 1942 onwards, methyl fluoroacetate has been studied extensively[1], and its toxicity (*L.D.* 50, 15 mgm./kgm. for mice) used as a standard reference figure for all new compounds prepared. Many of the salient pharmacological features have been reviewed[2,3]; it has been shown that the point of attack of these agents is either the central nervous system or the heart, and the *L.D.* 50 can vary from as low as 0·06 mgm./kgm. in the dog to well over 500 mgm./kgm. in the case of the South African clawed toad (*Xenopus laevis*). Death may result from: (*a*) respiratory arrest following severe convulsions; (*b*) gradual cardiac failure or ventricular fibrillation; or (*c*) progressive depression of the central nervous system with either respiratory or cardiac failure as the terminal event. A latent period varying from thirty minutes to several hours always occurs before the symptoms develop.

In 1947, a remarkable alternation in toxicity of members of an ascending homologous series of ω-fluorocarboxylic esters was reported[4,5]. Considering the general formula $F(CH_2)_nCOOR$, it was established that if n is odd ($n = 1, 3, 5, 7, 9, 11$), the compound is toxic and produces symptoms in animals similar to those produced by fluoroacetic acid, whereas if n is even ($n = 2, 4, 10$), the compound is devoid of toxic properties. In other words, those esters containing an even number of carbon atoms are toxic, whereas the odd-numbered members are innocuous.

This alternation in toxicity has been correlated with the β-oxidation theory of the breakdown of long-chain carboxylic acids in the animal body[6]. It can be seen that β-oxidation of the even-numbered members would yield the toxic fluoroacetic acid in all cases, whereas the odd-numbered members would be oxidized only so far as the non-toxic 3-fluoropropionic acid. Recently, this conclusion has been confirmed in part by the finding of citric acid in the brain of animals treated with sodium 4-fluorobutyrate or sodium 6-fluorohexanoate[7], indicating a partial conversion of these substances to fluoroacetate, the latter causing the accumulation of citric acid as described by Peters[8].

It was on account of the above observations that the present research project was initiated. Its purpose was two-fold: first, to study the chemistry of ω-fluoro-organic compounds, the reactions and properties of which are relatively unknown in contrast with those of the other often-studied ω-halogeno-compounds; and secondly, to obtain new fluorine compounds which we predicted would be of pharmacological interest.

Each new compound prepared was analysed in order to confirm its identity and purity, and all necessary physical constants were determined. A sample of each pure compound was then submitted for toxicity determinations on mice by subcutaneous injection using propylene glycol as solvent. In most cases, death was accompanied by typical fluoroacetate-like symptoms. Even though mice often give unreliable and inconsistent results compared to dogs and monkeys, they were used in this investigation on account of their ready availability. Moreover, since previous workers had used mice for toxicity screening, our continuation allowed ready correlation with related compounds.

This report surveys very briefly some of the toxicological results of various new series of aliphatic compounds containing an ω-fluorine atom. An attempt has been made to correlate chemical structure with toxicity, although this feature of the work is still incomplete. Full details of preparation, physical constants and analytical data, together with a more complete bibliography, will be presented in the appropriate journals in due course.

ω-*Fluorocarboxylic acids and derivatives*, $F(CH_2)_nCOOR$. For completeness, we prepared[9] the two missing members of the ω-fluorocarboxylate series mentioned above, ethyl 7-fluoroheptanoate, $F(CH_2)_6COOEt$, and ethyl 9-fluorononanoate, $F(CH_2)_8COOEt$. Both were non-toxic as expected. This added further confirmation to the β-oxidation theory and completed the first eleven members of the series. In no instance has an exception to the toxicity rule been found. One higher ester, ethyl 16-fluorohexadecanoate, $F(CH_2)_{15}COOEt$, was prepared[9] and as predicted had an *L.D.* 50 of about 7 mgm./kgm. The remarkable fact about this derivative was that toxic symptoms apparently developed much more rapidly than those caused by the standard, methyl fluoroacetate. These new derivatives were prepared from the corresponding ω-bromo-esters by halogen exchange using metallic fluorides. Recently, we have also prepared 18-fluorostearic acid, $F(CH_2)_{17}COOH$, by oxidation of 18-fluorooctadecanol, and preliminary work indicates that its toxicity is slightly greater than was expected, notwithstanding its very low solubility in aqueous media. Revised figures for the *L.D.* 50 of the ω-fluorocarboxylate series are shown in Table 1.

ω-*Fluoroalcohols*, $F(CH_2)_nOH$. The preparations of the above ω-fluorocarboxylates were all long and required *ad hoc* methods for each individual member. It seemed desirable to find a corresponding series, all the members of which could be obtained by a general method starting from cheap, readily accessible materials. Since the biological oxidation of alcohols to acids has long been known, the homologous series of ω-fluoroalcohols was next examined. The members prepared so far[9-11] are summarized in Table 1.

Once again a pronounced alternation in toxicity is apparent with ascent of the series, with the same

Table 1

Formula of ω-Fluoroalcohol	L.D. 50 for mice (mgm./kgm.)	Formula of corresponding ω-Fluorocarboxylate	L.D. 50 for mice (mgm./kgm.)
FCH_2CH_2OH	15	FCH_2COOCH_3	15
$F(CH_2)_3OH$	46·5	$F(CH_2)_2COOH$	> 100
$F(CH_2)_4OH$	0·9	$F(CH_2)_3COONa$	4·0
$F(CH_2)_5OH$	> 100	$F(CH_2)_4COOEt$	> 100
$F(CH_2)_6OH$	1·24	$F(CH_2)_5COONa$	3·0
$F(CH_2)_7OH$	80·0	$F(CH_2)_6COOEt$	> 100
$F(CH_2)_8OH$	0·6	$F(CH_2)_7COOEt$	9·0
$F(CH_2)_9OH$	32·0	$F(CH_2)_8COOEt$	> 100
$F(CH_2)_{10}OH$	1·0	$F(CH_2)_9COOEt$	10·0
$F(CH_2)_{11}OH$	> 100	$F(CH_2)_{10}COOEt$	> 100
$F(CH_2)_{12}OH$	1·5	$F(CH_2)_{11}COOH$	1·25
		$F(CH_2)_{15}COOEt$	7·0
$F(CH_2)_{18}OH$	4·0	$F(CH_2)_{17}COOH$	5·7

generalizations applying to the odd- and even-numbered homologues. Moreover, it can be seen that most members of the ω-fluoroalcohol series are considerably more toxic than the corresponding members of the ω-fluorocarboxylate series. In particular, 8-fluorooctanol is about fifteen times as toxic as ethyl 8-fluorooctanoate, and more than forty times as toxic as methyl fluoroacetate on a molar basis.

The synthesis of the ω-fluoroalcohols can be carried out by various general routes:

(1) $HO(CH_2)_nOH \xrightarrow{HCl} Cl(CH_2)_nOH \xrightarrow{KF} F(CH_2)_nOH$

(2) $X(CH_2)_nX \xrightarrow{KF} F(CH_2)_nX \xrightarrow{hydr.} F(CH_2)_nOH$

(3) $CH_2{=}CH(CH_2)_{n-2}OH \xrightarrow{HBr,\ air} Br(CH_2)_nOH \xrightarrow{KF} F(CH_2)_nOH$

(4) 
$$(CH_2)_{n-2}\langle CH_2, CH_2 \rangle O + HX \rightarrow X(CH_2)_nOH \xrightarrow{KF} F(CH_2)_nOH$$

(5) 
$$(CH_2)_{n-2}\langle CH_2, CH_2 \rangle O + HF \rightarrow F(CH_2)_nOH$$

(6) $F(CH_2)_{n-1}COOR \xrightarrow{LiAlH_4} F(CH_2)_nOH.$

All the above methods have been employed successfully for the preparation of at least one member of the ω-fluoroalcohol series, and most are general for the entire series. So far, route (1) has proved to be the most satisfactory because of the ready availability of the glycols, which in turn can be prepared from the corresponding dibasic acids.

Early in this work, we realized the need for a reducing agent which would reduce the functional groups of monofluorinated aliphatic derivatives without simultaneous loss of fluorine. The use of standard basic reducing agents was prohibited because of the ready removal of hydrogen fluoride with concomitant unsaturation or cyclization, while high-pressure hydrogenation readily formed the corresponding non-fluorinated material[9]. In spite of the basic nature of lithium aluminium hydride and of the reported dehalogenation of monohalogenated derivatives[13], we thought that this reagent might still be effective for our purpose due to the mild conditions employed in the reaction and to the greater stability of the carbon–fluorine bond relative to that of the other carbon–halogen bonds. This theory has now been verified experimentally[11], and lithium aluminium hydride has been used to advantage in route (6) for the reduction of ethyl 11-fluoroundecanoate to 11-fluoroundecanol (96 per cent yield), and of 12-fluorododecanoic acid to 12-fluorododecanol (50 per cent yield). Further reference to other reductions will be made later, in particular to the reduction of fluorinated nitriles and nitro-compounds to fluorinated amines[11,12], and of fluorinated thiocyanates to fluorinated mercaptans[11].

ω-*Fluoroaldehydes*, $F(CH_2)_nCHO$. Fluoroacetaldehyde, FCH_2CHO, the simplest member of the series, has been reported[14] to have a toxicity similar to that of methyl fluoroacetate and fluoroethanol. It was never isolated in a pure state, since the anhydrous material polymerized rapidly, and all toxicity studies were carried out on the hydrate, $FCH_2.CH(OH)_2$.

The ω-fluoroaldehydes were expected to follow the toxicities of the corresponding acids and alcohols, and in confirmation of this we have prepared[11] 10-fluorodecanal, $F(CH_2)_9CHO$, the aldehyde corresponding to 10-fluorodecanol.

The compound was made by the method outlined below:

$$HO(CH_2)_9CH{=}CH_2 \xrightarrow{PBr_3} Br(CH_2)_9CH{=}CH_2 \xrightarrow{KF}$$

$$F(CH_2)_9CH{=}CH_2 \xrightarrow{H.COOOH} F(CH_2)_9CH(OH)CH_2OH$$

$$\xrightarrow{KIO_4} F(CH_2)_9CHO.$$

The *L.D.* 50 of 10-fluorodecanal as determined by subcutaneous injection into mice was 1·95 mgm./kgm., that is to say, its toxicity is almost identical with that of 10-fluorodecanol. This adds further evidence of the ready interconversion of alcohols, aldehydes and acids *in vivo*.

It is of interest that the intermediate 11-fluoro-1,2-dihydroxyundecane, $F(CH_2)_9CH(OH).CH_2OH$, has an *L.D.* 50 of 1·75 mgm./kgm., that is, very similar to that of 10-fluorodecanal, $F(CH_2)_9CHO$, and in contrast to the non-toxic 11-fluoroundecanol, $F(CH_2)_9CH_2CH_2OH$. It seems probable, then, that the α-glycol grouping of 11-fluoro-1,2-dihydroxyundecane is being split *in vivo* to yield the toxic 10-fluoroaldehyde and afterwards 10-fluorodecanoic acid. This type of reasoning, although based on such scanty data as crude toxicity figures, affords the first evidence for the metabolic scission of α-glycols and at the same time illustrates an application of fluorine compounds to the study of biochemical mechanisms.

ω-*Fluoronitriles*, $F(CH_2)_nCN$. These derivatives were originally prepared for comparison with the parent acids. Moreover, from a consideration of the reported breakdown of nitriles *in vivo* to hydrogen cyanide and the next lower acid[15], it seemed probable that the nitriles with an odd number of carbon atoms might be more toxic than the even-numbered members. For example:

$F(CH_2)_4CN \rightarrow F(CH_2)_3COOH$ (toxic) + HCN (toxic).

The members already prepared[11] support this hypothesis, as is shown in Table 2.

Table 2

Compound	Formula	L.D. 50 for mice (mgm./kgm.)
Fluoroacetonitrile	FCH_2CN	25
4-Fluorobutyronitrile	$F(CH_2)_3CN$	16
5-Fluorovaleronitrile	$F(CH_2)_4CN$	1·0
6-Fluorohexanonitrile	$F(CH_2)_5CN$	50
7-Fluoroheptanonitrile	$F(CH_2)_6CN$	2·7
12-Fluorododecanonitrile	$F(CH_2)_{11}CN$	80

The contribution of the hydrogen cyanide to the overall effect is indicated by the decrease in toxicity with ascent of the even-numbered members of the series.

Again, biochemical conclusions can be drawn from these toxicity figures. It can be seen: (*a*) that the nitriles are not hydrolysed appreciably *in vivo* by the standard chemical route ($R.CN \rightarrow R.COOH$), since the toxic odd members would give rise to non-toxic acids, whereas the reverse is the case; (*b*) that they are not reduced *in vivo* to the corresponding amines ($R.CN \rightarrow R.CH_2NH_2$) since the toxic odd members would give rise to amines containing an odd number of carbon atoms, and these are shown in the next section to be non-toxic; but (*c*) that, on the contrary, the most satisfactory way of explaining the high toxicity of the odd members is to accept the somewhat implausible theory of C—CN rupture, giving the toxic even-numbered fluoro-acids plus hydrogen cyanide. This work thus confirms the original postulate of nitrile metabolism.

The ω-fluoronitriles were prepared easily and in very good yield by treatment of the corresponding ω-fluoroalkyl halides with sodium cyanide.

ω-Fluoroalkylamines, $F(CH_2)_nNH_2$. ω-Fluoro-primary amines were examined in accordance with the routine preparation and screening of ω-fluoro-derivatives. The even-numbered members were expected to be toxic on the grounds that normal amines undergo detoxication to the corresponding acid[17].

$$F(CH_2)_5CH_2NH_2 \rightarrow F(CH_2)_5CH{=}NH \rightarrow F(CH_2)_5CHO \rightarrow F(CH_2)_5COOH \text{ (toxic).}$$

The four members which we have prepared[11,13] substantiate this general hypothesis as is shown in Table 3.

Table 3

Compound	Formula	*L.D.* 50 for mice (mgm./kgm.)
3-Fluoropropylamine	$F(CH_2)_3NH_2$	46
5-Fluoroamylamine	$F(CH_2)_5NH_2$	50
6-Fluorohexylamine	$F(CH_2)_6NH_2$	0·9
7 Fluoroheptylamine	$F(CH_2)_7NH_2$	50

Further members are being investigated, in particular, 2-fluoroethylamine, which has been prepared previously[18], 4-fluorobutylamine and 8-fluorooctylamine.

The ω-fluoroalkylamines were prepared by reduction of the corresponding ω-fluoronitriles using lithium aluminium hydride, or of the corresponding ω-fluoro-ω′-nitroalkanes using either lithium aluminium hydride or catalytic low-pressure hydrogenation.

ω-Fluoro-ω′-nitroalkanes, $F(CH_2)_nNO_2$. The four members listed in Table 4 were prepared[13,15] by treating the corresponding ω-fluoroalkyl bromide with silver nitrite in boiling ether. Once again, an alternation in toxicity is apparent.

The minimum lethal doses of the lower non-fluorinated mononitroalkanes lie between 250 and 1,000 mgm./kgm. when these compounds are administered orally to rabbits[19]. It has been shown[20,21] that when nitroethane is administered intravenously to rabbits, the main metabolic products are acetaldehyde and nitrite ions, with smaller amounts of acetic acid and nitrate ions. Similar products were obtained *in vitro* using hydrogen peroxide as the oxidizing medium:

Table 4

Compound	Formula	*L.D.* 50 for mice (mgm./kgm.)
3-Fluoro-1-nitropropane	$F(CH_2)_3NO_2$	92
4-Fluoro-1-nitrobutane	$F(CH_2)_4NO_2$	11
5-Fluoro-1-nitropentane	$F(CH_2)_5NO_2$	90
6-Fluoro-1-nitrohexane	$F(CH_2)_6NO_2$	12 5

$$CH_3CH_2NO_2 + H_2O_2 \rightarrow CH_3.CHO + HNO_2 + H_2O.$$

The presence of acetic acid and nitrate ions was attributed to secondary oxidation of the main products. Assuming that the ω-fluoro-ω′-nitroalkanes follow the same metabolic pathway, the expected products are the corresponding aldehydes and acids, together with nitrite and nitrate ions. Accordingly, it is postulated that the toxicity of the ω-fluoro-ω′-nitroalkanes is due in part to the formation of the corresponding ω-fluoro-carboxylic acids and that the even-carbon members are the more toxic due to the higher toxicity of the even-carbon fluoro-acids.

Summary

Representative members of various chemical species containing an ω-fluorine atom have been prepared and tested on mice by subcutaneous injection; chemical series described in this report include ω-fluorocarboxylates, ω-fluoroalcohols, ω-fluoroaldehydes, ω-fluoronitriles, ω-fluoroamines and ω-fluoro-ω′-nitroalkanes. An attempt has been made to correlate the toxicities with known metabolic mechanisms. A second report will survey our work on the following and other topics: ω-fluoro-halogen derivatives, several types of ω-fluoro-sulphur derivatives, ω-fluoroalkenes and ω-fluoroalkynes, methods of fluorination, new synthetic routes and possible commercial outlets for these materials.

We are indebted to the Defence Research Board of Canada for funds to provide salaries, chemicals and apparatus (Contract *DRB X*-24), and for permission to publish this work. We are very grateful to Dr. M. K. McPhail and Mr. P. A. Adie, Suffield Experimental Station, Ralston, Alberta, for carrying out the toxicity determinations.

The following have collaborated in this work: R. M. Hill, W. C. Howell, S. B. D. Hunt, A. J. McNamara, J. C. Schneider, J. F. Walker and R. W. White.

Reproducibility of Differential Centrifugation Experiments in Tissue Fractionation

During the past few years, differential centrifugation of tissue homogenates has become one of the major techniques of cytology and biochemistry alike. Most of those who have applied this new technique describe the conditions of centrifugation by mentioning only the duration of operation and the centrifugal field prevailing in the middle (or at the bottom) of the tube; the type of centrifuge used is sometimes also mentioned. However, the information thus supplied is not sufficient to enable other workers to reproduce the conditions, especially when another type of instrument is to be used. This fact may be partly responsible for the wide variations which are sometimes encountered between results obtained in different laboratories.

Since different types of instruments cannot be expected ever to furnish identical results, the definition of a suitable unit raises some difficulties in itself. However, if the approximation is made that angle centrifuges can be regarded as similar to radial centrifuges in which the top and bottom of the fluid are separated from the axis by the same distances[1], different instruments become comparable with each other and the formula of sedimentation in a radial direction can be applied. When used for preparative purposes, a centrifugation is then best described by the characteristics of the lightest spherical particles which are completely sedimented under the conditions used.

The relationship between the variables involved is given by the formula:

$$2\cdot3\,\log_{10}\frac{R_{\text{max.}}}{R_{\text{min.}}} = \frac{2r^2\,(d_p - d_m)}{9\eta}\int_0^t \omega^2 dt, \qquad (1)$$

in which $R_{\text{max.}}$ and $R_{\text{min.}}$ are the distances (in cm.) separating the bottom and the surface of the fluid respectively from the axis during centrifugation; r is the radius of the particle (in cm.); d_p and d_m are the densities of the particle and of the medium respectively (in gm./cm.^{3}); η is the viscosity of the medium (in poises); ω is the angular velocity (in rad./sec.); and t is the time (in sec.).

From this formula, three values are required: $R_{\text{max.}}$, a characteristic of the instrument and, eventually, of the type of tube used; $R_{\text{min.}}$, a value which is dependent on the type of instrument and tube, and also on the amount of fluid centrifuged; $\int_0^t \omega^2 dt$, the time integral of the squared angular velocity.

With instruments which accelerate and decelerate rapidly, and which are run during a relatively long time, the latter value is described accurately enough by giving the time during which the power is turned on and the angular velocity at plateau speed. When such is not the case, it is necessary to work out the whole integral. It can then be expressed by means of the actual time of operation and of the equivalent mean angular velocity.

Another alternative would be to give simply the sedimentation constant of the lightest spherical particles which are sedimented completely:

$$s = \frac{2r^2\,(d_p - d_m)}{9\eta} = \frac{2\cdot3\,\log_{10}\dfrac{R_{\text{max.}}}{R_{\text{min.}}}}{\displaystyle\int_0^t \omega^2 dt}. \qquad (2)$$

It should be pointed out that the use of the average field, expressed in terms of the gravity constant g rather than the angular velocity, tends to render results less reproducible.

If the average field is defined as the field prevailing at a distance $R_{\text{av.}} = 0\cdot5\,(R_{\text{max}} + R_{\text{min}})$ from the axis

$$g_{\text{av.}} = \frac{1}{981}\,\omega^2 R_{\text{av.}}; \qquad (3)$$

equation (2) then becomes:

$$s = \frac{2\cdot3\,R_{\text{av.}}\,\log_{10}\dfrac{R_{\text{max.}}}{R_{\text{min.}}}}{981\displaystyle\int_0^t g_{\text{av.}}\,dt}. \qquad (4)$$

Since individual centrifuges differ more by the absolute values of their radii than by the ratio of these values, they are less comparable, so far as complete sedimentation is concerned, when developing equal average fields than when turning at equal velocities. The converse is obviously true when the rate of sedimentation in the middle of the tube is considered. But in preparative centrifugation, it seems more logical to use complete sedimentation as criterion of comparison.

One can, of course, maintain the convention of expressing the conditions of centrifugation by means of the average field; but it then becomes of special importance to give the values of $R_{\text{max.}}$ and $R_{\text{min.}}$ accurately. In this case, the time integral of the average field can be conveniently expressed in a composite unit, g.min., or alternatively, as the equivalent of x minutes at y times g. If, as is usually the case, the angular velocity is expressed in revolutions per minute (r.p.m.) and the time T in minutes, equations (2) and (4) become:

$$s = 3\cdot5\,\frac{\log_{10}\dfrac{R_{\text{max.}}}{R_{\text{min.}}}}{\displaystyle\int_0^T (\text{r.p.m.})^2\,dT} = 3\cdot9\times10^{-5}\,\frac{R_{\text{av.}}\,\log_{10}\dfrac{R_{\text{max.}}}{R_{\text{min.}}}}{\displaystyle\int_0^T g_{\text{av.}}\,dT}. \qquad (5)$$

In equations (2), (4) and (5), s is given in sec.; it can also be expressed in Svedberg units (10^{-13} sec.) and must then, of course, be multiplied by 10^{13}.

There is little doubt that better reproducibility will be obtained if the conversion from one instrument to another is based on one of these equations. Of course, differences must still be expected, since the equations are based on an approximation in the first place, and also they neglect such factors as diffusion and convection currents, which may be more important in one type of instrument than in another. In addition, the manner in which decantation is performed may be of paramount importance and should be mentioned as well.

Enzymic Content of the Mitochondria Fraction

A LARGE number of enzymes have been located in the mitochondria fraction isolated by means of differential centrifugation; this fact is generally assumed to indicate that they are structurally associated within the living cell. Recent studies, part of which were presented at the second International Congress of Biochemistry[1], have shown that this conclusion is not necessarily warranted. It has been found that the acid phosphatase of rat liver, which comes down predominantly with the large granules in a form which, in the native particles, is practically devoid of activity towards added glycerophosphate at pH 5 [2-4], does not belong to the same type of granules as cytochrome oxidase.

The phosphatase-containing granules require larger centrifugal fields in order to sediment completely than do those bearing cytochrome oxidase, and can be further separated from the latter by washing or by a layering technique. The sedimentation properties of the two classes resemble each other too closely to permit a complete separation; but it is possible to isolate head fractions which are very rich in cytochrome oxidase and almost free from acid phosphatase and tail fractions showing a reverse relationship.

Similar observations have been described by Novikoff, Podber, Ryan and Noe[5], but have been interpreted by these authors as showing that the cytoplasmic granules have a heterogeneous enzymic composition. Our contention, on the other hand, is that granules of a given class may be homogeneous, but that the isolated fractions are heterogeneous and contain representatives of several distinct classes. This contention is theoretically acceptable, since contaminations must be considered inevitable in differential centrifugation; it is supported by the efficiency of washing as a means of further dissociating the two activities, and by the finding that the distribution of rhodanase among all isolated fractions is identical, within experimental errors, to that of cytochrome oxidase[1].

More recent investigations have led to the identification of two additional enzymes resembling acid phosphatase in all their cytological properties, namely, β-glucuronidase and cathepsin, both of which had already been shown to be concentrated in the mitochondria fraction, by Walker[6] and by Maver and Greco[7], respectively. Not only do these enzymes follow acid phosphatase closely during centrifugation, but they also exhibit its other peculiar properties. Like acid phosphatase, they have little activity towards their respective substrates (phenolphthalein glucuronide and hæmoglobin) when the intact granules are incubated during a short time at 37° and pH 5 in a medium made isotonic with sucrose. They are also released in soluble form and simultaneously activated when the granules are disrupted in the Waring blendor, frozen and thawed several times, or exposed to hypotonic media or to salt solutions. These properties had already been noted by Walker[6] in the case of β-glucuronidase. When the activating procedure is graded so as to release only part of the enzymes, all three are liberated in the same proportion. An integrated picture of all these results is shown in Fig. 1.

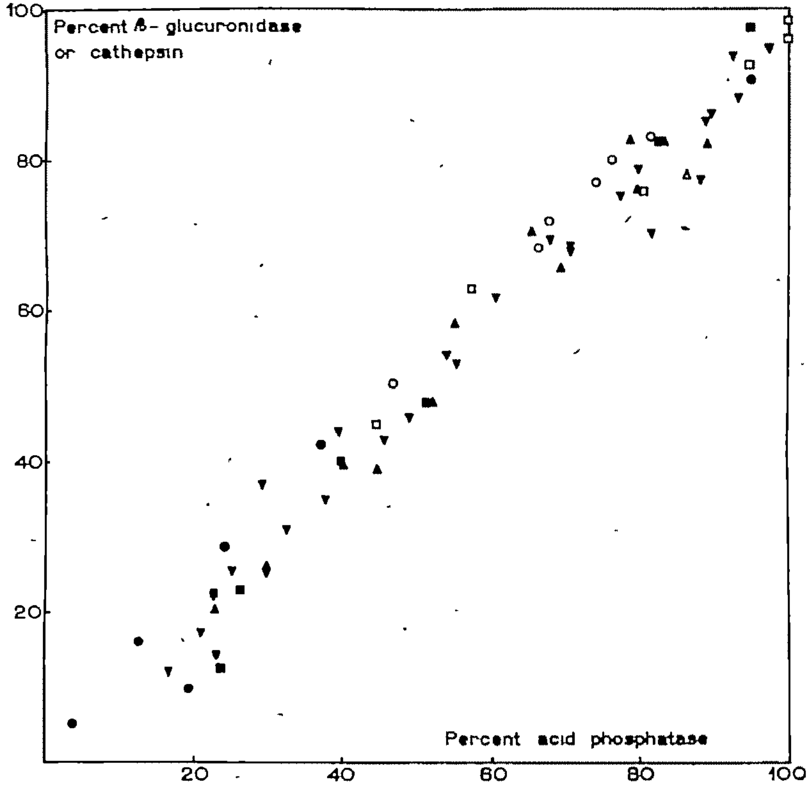

Fig. 1. Correlation between β-glucuronidase, cathepsin and acid phosphatase. White signs: β-glucuronidase; black signs; cathepsin.

Circles: Total activity of fractions isolated by differential centrifugation, as percentage of activity of homogenate.

Squares: Free activity of washed granules treated for various times in the Waring blendor, as percentage of total activity of the preparation.

Upward triangles: Same as above, but with granules frozen and thawed a number of times.

Downward triangles: Same as above, but with granules exposed to sucrose solutions of varying hypotonicity.

Total activities measured on completely disrupted preparations; free activities determined in 0·25 M sucrose, during 10 min.

These findings afford strong support to the theory outlined above that there are two distinct classes of large granules, having a different but homogeneous enzymic content. They also strengthen the osmotic interpretation given in earlier papers[2-4], according to which acid phosphatase is retained within the granules by a semipermeable membrane having a low degree of permeability to its substrate, for it is now found that three different proteins are released in the same proportion when the preparation is subjected to partial damage. Finally, the fact that the same percentage of all three enzymes is found in free form in homogenates furnishes additional support to the opinion, already expressed in the case of acid phosphatase[2,3], that the enzymes are entirely bound to particles in the intact cell.

The cytological nature and function of these granules raise intriguing problems. Judging from their sedimentation properties, they resemble mitochondria rather than microsomes, and cannot belong to the latter class, since they can be separated to a large extent from glucose-6-phosphatase, a typical microsomal enzyme[6]. They are not specially concentrated either in the poorly sedimented 'fluffy layer', which is found on top of the mitochondrial precipitate and which has been studied by several authors[4,9,10]. So far as can be judged at the present time, they could even form a small proportion of the total number of granules present in the mitochondria fraction, which would make their cytological identification very difficult.

In view of these observations, the significance of results indicating that a given enzyme is concentrated in the mitochondria fraction must remain uncertain, as long as it has not been identified as belonging to one or the other of the two classes of granules described in this communication.

A detailed account of these experiments will be submitted for publication in the *Biochemical Journal*. They have been supported by grants from the Centre National de Recherches sur la Croissance normale et pathologique, the Lilly Research Laboratories and the Rockefeller Foundation.

Giant Condensation Nuclei from Bursting Bubbles

AMONG cloud physics workers there is increasing recognition that the larger of the salt nuclei that are found in the air may initiate rain by coalescence in clouds. Hence mechanisms which produce these nuclei at ocean surfaces are of special interest. Köhler[1] has suggested that they result from spray formed by the action of strong winds on wave crests. More recently, Aliverti and Lovera[2] have related the production of minute salt particles to the presence of bursting bubbles at the sea surface, and Facy[3] has suggested that the particles result from the shattering of the thin water-films present in clusters of bubbles.

At the Woods Hole Oceanographic Institution, high-speed motion pictures (more than 3,000 frames sec.$^{-1}$) of small bubbles bursting at the water surface have revealed one of the processes which bring about the formation of the larger salt nuclei. Fig. 1 illustrates some of the stages in the collapse of small bubbles and the production of jets, and Fig. 2 shows a jet producing droplets. Smaller bubbles are observed to form jets more rapidly and to eject much smaller droplets into the air. The bubble cavities and jets observed are similar in form to some of Worthington's 'splashes'[4], and confirm Stuhlman's[5] assumption that jets are formed by small bubbles bursting at the surface of distilled water.

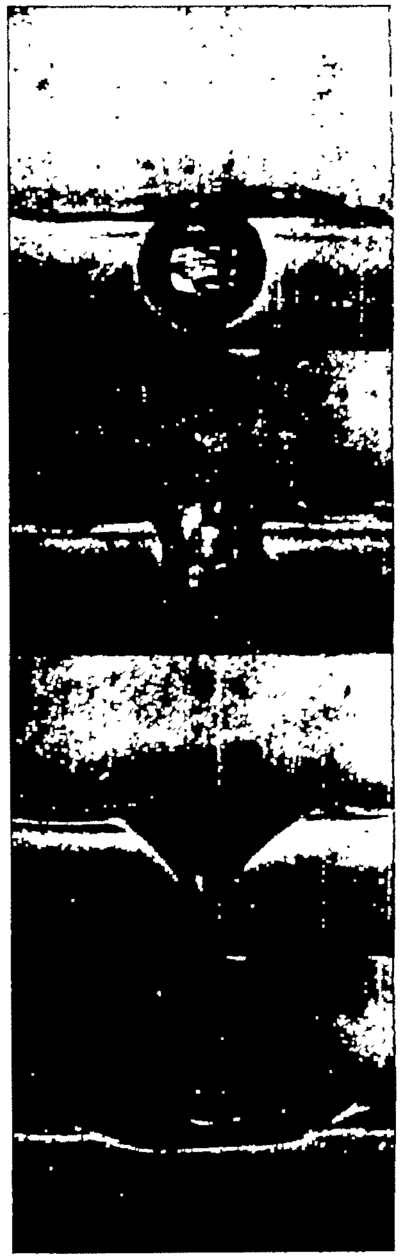

Fig. 1. Composite photograph of high-speed motion pictures illustrating some of the stages in the collapse of small bubbles and the formation of jets. Time interval between top and bottom frames about 2·3 milliseconds. Bubble diameter, 1·7 mm.; angle of view horizontal through glass wall. (Surface irregularities due to meniscus.)

Each bubble ejects about five droplets, the heights of projection ranging from about 0·5 to 15 cm.

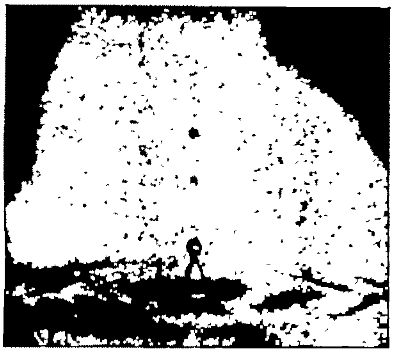

Fig. 2. Oblique view of jet from 1·0 mm. diameter bubble. Diameter of smallest droplet shown, 0·09 mm. Exposure time, 30 μsec.

Photographic studies have been made of bubbles ranging in size from 0·2 to 0·02 cm. diameter, though smaller bubbles are also observed to form jets and droplets. When bubbles burst in sea water, evaporation of the water from the droplets formed by the jets is observed to leave a salt residue which in many cases is similar in weight to salt nuclei found in the atmosphere. It is inferred that many of the larger sea-salt nuclei found in the atmosphere[6] originate in this manner from bubbles naturally formed in surface waters of the seas.

More complete information about this photographic study of bursting bubbles is to be published in the near future.

This study was supported by the Office of Naval Research, under contract number Nonr-798(00) (NR-082-124).

Density of Deposited Carbon

Many gaseous compounds of carbon, when passed over a heated surface, deposit on it elemental carbon, the form of which depends on the temperature of the surface[1].

We have deposited coatings of carbon 1–2 mm. thick on graphite rods. The densities of the deposits were determined using a flotation technique. The depositions were carried out using a closed vessel containing methane at an initial pressure of approximately 15 cm. mercury, in which a graphite rod 5½ mm. in diameter was raised to the desired temperature by resistance heating, and maintained at this temperature until the pressure became constant.

The variation of the density of the coating obtained with the temperature of deposition is shown in Fig. 1. The maximum density found was 2·22 gm./cm.^{3}; this approaches closely the theoretical lattice density[2] of 2·265 gm./cm.^{3}.

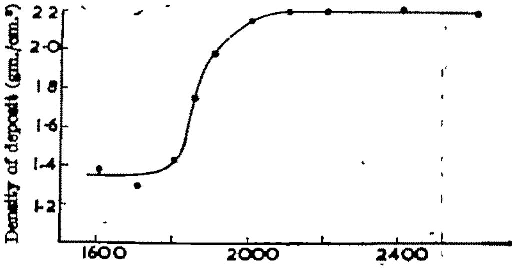

Fig. 1

Variation of the initial pressure of the methane at the lower temperatures was also investigated, and the preliminary results are shown in Fig. 2.

Summarizing the results, it may be stated that the density of the carbon deposited from methane at an initial pressure of 15 cm. attains a maximum value approximating to the theoretical density of graphite as the temperature of deposition is increased, and probably a lower limiting value as the temperature is lowered. Further, at a given temperature, the density of the deposit increases with increase of initial pressure of methane.

X-ray examination shows that the high-density deposits consist of sheets of graphitic carbon the c-axes of which are aligned approximately normal to the surface of the original rod, but which are otherwise randomly oriented. A deposit of lower density showed a similar structure with less pronounced alignment, but also contained material which was apparently not graphitic in structure.

The microstructure of the deposits was investigated using normal metallographic techniques, and is shown in Figs. 3 and 4. No differences between the high- and low-density deposits have been detected microscopically.

Preliminary measurements of electrical resistivity at room temperature indicate considerable variation of the specific resistance with density. The specific resistance of the high-density deposits measured parallel to the axis of the original rod was of the order 35 × 10^{-4} ohm cm. It therefore falls between that for natural graphites[3], 39–60 × 10^{-4} ohm cm., and that for commercial graphites[4], 65–120 × 10^{-4} ohm cm. The grain boundaries visible in Figs. 3 and 4 may be the cause of the high resistance as compared with natural graphite.

Such variations as have been detected may be of considerable importance when considering both the fundamental properties of deposited carbon, for example, chemical reactivity, and its technical applications. Many workers[5] have used carbon filaments coated with material deposited from hydrocarbons at high temperatures and low pressures to

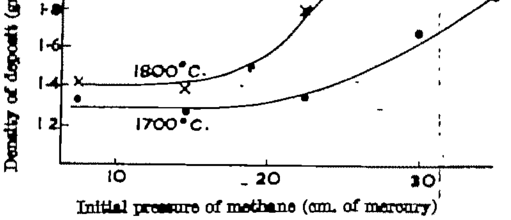

Fig. 2

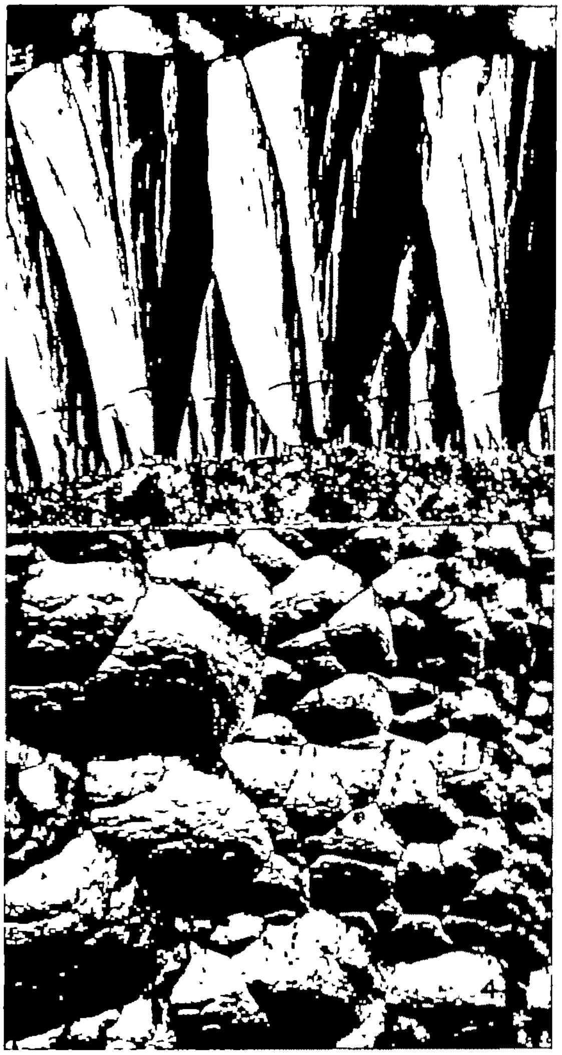

Fig. 3 (above). Cross-section. Fig. 4 (below). Longitudinal section. Polarized light, crossed Nicols, × 100. (Crown copyright reserved)

investigate the kinetics of the oxidation of carbon. No details concerning the densities of the deposits are given, and it would appear that correlation of results obtained with such materials will be uncertain without this information.

A fuller investigation of the phenomena reported is in progress, and it is hoped to issue a more detailed account at a later date.

We wish to acknowledge the assistance of Mr. D. Clark, who undertook the X-ray examination of the specimens. Acknowledgment is also made to the Chief Scientist, Ministry of Supply, for permission to publish this communication.

Experimental Data and Model Structures for the Insulin Molecule

Two recent communications[1,2] have described the results of stereochemical model studies of insulin based on the α-helix structure and using the detailed amino-acid residue sequences established by Sanger and his associates[3]. Both studies were made using identical packing models[4] in which the fundamental residue unit (—NH.CH(*R*).CO—) dimensions are different from those derived by Pauling and Corey[5] from experimental studies of amino-acid and peptide structures. The cystine residue bond-lengths and bond-angles recorded by Arndt and Riley[5] differ markedly from those found by Yakel and Hughes[6] in N.N′-diglycyl-L-cystine. While local deviations in bond-lengths and bond-angles of the residue units and of the hydrogen bonds, brought about by side-chain (*R*) group interactions, may perhaps be expected along the peptide chain of a native protein, the overall use of dimensions which differ considerably from the experimentally derived values appears to be a purely arbitrary procedure.

The α-helix structure may exist in insulin; it is certainly an attractive possibility since the α-helix is energetically the most stable polypeptide chain configuration, and has been shown to occur in synthetic polypeptides. Further, the X-ray scattering curve[7] from powdered insulin appears closely comparable to the radial distribution function for a mixture of left-handed (L) and right-handed (R) α-helices. X-ray studies[8] of the vector structure of air-dried acid insulin sulphate crystals strongly suggest that the molecule is made up of parallel coiled (or folded) polypeptide chains with parallel close-packed intermolecular association, oriented along the *a*-axis. The length of the *B*-chain of insulin coiled in an α-helix is approximately 44 A., the length of the *a*-axis. The maximum cross-section area for each close-packed chain is 12·85 A. × 7·6 A.; thus, in order to give a reasonable value for the partial specific volume of insulin, an average unit residue translation along the chain of approximately 1·5 A. is required.

The chains in insulin are linked together by —S—S— bonds. In an earlier scale-model study[9] of the insulin structure using van der Waals packing models and the Pauling–Corey α-helix, attempts were made to describe all the ways in which four ($2A+2B$) or two ($A+B$) chains could be joined together by cystine linkages. The study was restricted to structures with either all L- or all R-helices. The chains were required to be parallel to each other and at a minimum interchain distance of approximately 10 A. Intra-chain cystine linkages between the 6 and 7 or 7 and 11 *A* chain positions were not possible and this appeared to eliminate the two-chain model. At that time it appeared that only two (namely, 2L or 2R) four-chain structures were possible, both linear arrays one chain thick. A single-row model is difficult to accommodate in the unit cell and cannot form a close-packed array unless the asymmetrical unit is the two-chain ($A+B$) structure. The details of the vector structure and the packing limitations imposed by the geometrical relationship between rhombohedral zinc insulin and acid insulin sulphate crystals both strongly suggest the the four-chain unit is close-packed. Two acceptable close-packed arrays have been suggested[9,10], shown (in cross-section) diagrammatically below, where the *A*- and *B*-type chains are represented by ellipses of different eccentricities:

In a more recent study, completely rigid wire models of the Pauling–Corey[5b] α-helix were prepared. Only the half cystine —(β)C—S— residues were attached and these had the dimensions suggested by the N.N′-diglycyl-L-cystine[6] study. These models ncreased the number of formally possible four-chain tructures to the twelve single-row models described by Robinson[1], and confirmed the conclusion that two-chain structures could not be formed. If small cumulative changes in the helical angle are permitted, close-packed four-chain α-helix structures may be possible. The Arndt and Riley insulin models cannot be set up with the detailed dimensions of the Pauling–Corey α-helix structure.

From the studies of Harfenist and Craig[10], it now appears very probable that the four-chain 'molecule' is a dimeric association of two 5,733 molecular weight $A+B$) monomers. If this is so, and the chains are not folded back on themselves, there must be an A_{7-11} ntra-chain cystine linkage. Such a bond cannot be ormed either with the 3·6 α-helix or with a 3·9 helix (1·4 A. translation per unit residue) based on the Pauling–Corey dimensions. To maintain the α-helical configuration in the A_{7-11} region with an intra-chain —S—S— linkage involves extensive linear (>0·1 A.) and angular (>10°) distortions of bonds in both the backbone peptide chain and the cystine linkage. If a transition from α- to π-helix through a bifurcated hydrogen bond should take place at both boundaries of the A_{7-11} region, the distortions involved in forming an intra-chain —S—S— bond would be minimized. The α-helix may not occur at all in insulin or, in certain regions of the chain, disordered non-residue equivalent configurations may exist. The model study does show that a two-chain classical α-helix model is not wholly acceptable, and serves to emphasize that in a naturally occurring polyfunctional peptide chain the side-chain groups must control to a very large extent the detailed local-chain configuration.

Equations of Motion for Continuous Matter of Special Relativity in the Lagrange Variables

THE equations of motion for continuous matter of special relativity are usually[1] deduced by equating to zero the divergence of the material energy (the 'Minkowski') tensor:

$$\rho v_\mu v_\nu + \delta_{\mu\nu} p, \tag{1}$$

where ρ is the rest density and p is the pressure supposed given as a function of the x_μ. v_μ means dx_μ/ds. In this way we get the equation of continuity:

$$\frac{\partial \rho v_\mu}{\partial x_\mu} + \frac{dp}{ds} = 0. \tag{2}$$

dp/ds is considered small and is usually ignored; in fact, it represents the action of the pressure in creating matter[3]. We further get for the equations of motion (ignoring dp/ds):

$$\frac{\partial v_\mu}{\partial x_\nu} v_\nu + \frac{1}{\rho}\frac{\partial p}{\partial x_\mu} = 0. \tag{3}$$

These equations may be called the Euler equations, since the first three equations in (3) are the Euler equations of classical hydrodynamics.

What may be called the Lagrangian equations of special relativity may be deduced from the stationary principle:

$$\delta \int L \, d^4x = \delta \int \{\rho(v_\mu v_\mu)^{1/2} - p\} \, d^4x = 0. \tag{4}$$

Here the position of the particle of matter is denoted by y_μ, and v_μ means dy_μ/ds. The x_μ now constitute an arbitrary frame of reference. It is necessary to assume separately the Lagrangian equation of continuity. This is done by thinking of the matter as contained in a portion of a space-like surface which has been parametrized by three parameters u_1, u_2, u_3, and the equation of continuity is then:

$$\rho\Gamma = \rho_1\Gamma_1, \tag{5}$$

where $-\Gamma^2$ is the determinant $\left|\frac{\partial y_\mu}{\partial u_r}\frac{\partial y_\mu}{\partial u_s}\right|$, and $\rho_1\Gamma_1$ is the value of $\rho\Gamma$ at some initial time. The variation of the integral (4) gives the equations of motion:

$$\frac{dv_\mu}{ds} + \frac{1}{\rho}\frac{\partial p}{\partial y_\mu} = 0. \tag{6}$$

These are obviously the Lagrangian equations in relativistic form.

Equations (6) can, however, also be written:

$$\frac{\partial v_\mu}{\partial y_\nu} v_\nu + \frac{1}{\rho}\frac{\partial p}{\partial y_\mu} = 0,$$

which are the same as (3). Hence the distinction between the Lagrange and the Euler variables disappears in four dimensions.

The confusing relation:

$$\frac{Dv_k}{Dt} \equiv \frac{\partial v_k}{\partial t} + \frac{\partial v_k}{\partial x_r} v_r = \frac{dx_k}{dt},$$

between the Euler velocity and the Lagrange velocity of classical hydrodynamics now becomes clearer. The 't' of the Lagrange variables is really the proper time s.

There is also an interesting relationship between the Euler equation of continuity $\partial \rho v_\mu/\partial x_\mu = 0$ and the Lagrange equation $\rho\Gamma = \rho_1\Gamma_1$. They are just the two sides of Gauss's theorem applied to a small four-dimensional volume.

The discrepancy between (6) and (3) which arises, if the term dp/ds in (2) is not neglected, is easily remedied by allowing for the creation of matter by the action of pressure in the Lagrange equation of continuity (5) also, by writing it:

$$\rho\Gamma\,d^4u - \rho_1\Gamma_1\,d^4u + \int_{V(\Gamma d^4u)} \frac{dp}{ds}\,d\tau = 0.$$

The volume integration is over the four-dimensional volume swept out by the area Γd^4u.

A detailed account of the above results together with a discussion of the relationship between the Minkowski tensor and canonical tensor deduced from the Lagrangian used in (4) will be published elsewhere. I thank Prof. P. A. M. Dirac for his interest in this work.

A Fundamental Law of Geochemistry

THE late V. M. Goldschmidt defined one principal task of geochemistry as being, "to find the laws of distribution of the elements". One such law may apparently be found by close scrutiny of fully quantitative determinations of many elements in a comparatively large number of specimens of some specific rock or mineral type.

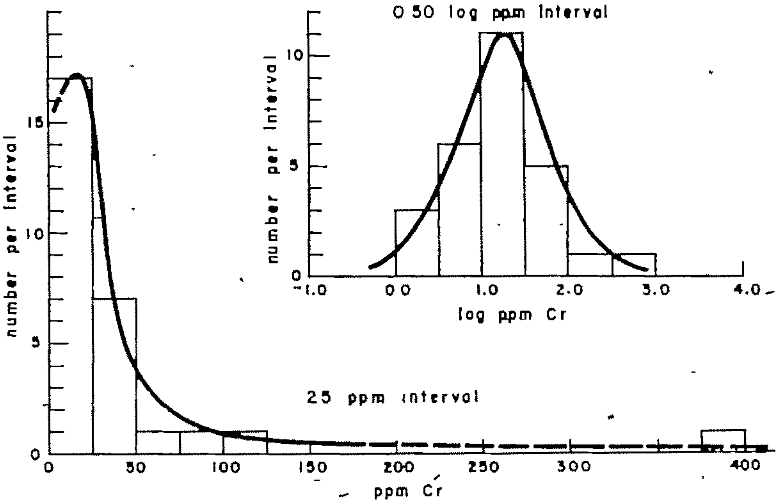

Fig. 1. Chromium in Canadian granite. Distribution of chromium content shows extreme positive skewness whereas the (log) content is normally distributed. Dispersion is large ($\sigma > 150$ per cent)

The determinations of potassium, rubidium, scandium, vanadium, cobalt, gallium, chromium and zirconium in diabase (Fairbairn, Ahrens and Gorfinkle[1]) and potassium, rubidium, caesium, lead, scandium, vanadium, cobalt, chromium and zirconium (Ahrens[2]); molybdenum (Sandell[3]) and fluorine (Seraphim[4]) in granite have been examined statistically, and the conclusions reached are: first, frequency distribution plots of the usual type (for example, Fig. 1) assume a decided positive skewness when the dispersion of an element is large—hence, distribution is not normal although it may appear to be so for those elements which show small dispersion (for example, Fig. 2); secondly, distribution becomes normal in all examples, irrespective of the magnitude of the dispersion, when concentration (the variate) is transformed to log concentration (see Figs. 1 and 2). As the total number of observations is reasonably large (812) and as they refer to a variety of distinctly different elements, the following fundamental geochemical law concerning the nature of the distribution of elements may be enunciated with some confidence: the concentration of an element is lognormall distributed in a specific igneous rock.

It follows directly from this law that the abundanc (arithmetic mean or average) of an element is alway greater than the most prevalent concentration, whicl in a lognormal distribution is given by the geometri mean. The difference is determined solely by th magnitude of the dispersion. In the above examples, the abundance and most prevalent concentration of rubidium are virtually identical whereas the abundance of chromium (40 p.p.m. is more than twice its most prevalent concentratio (17 p.p.m.).

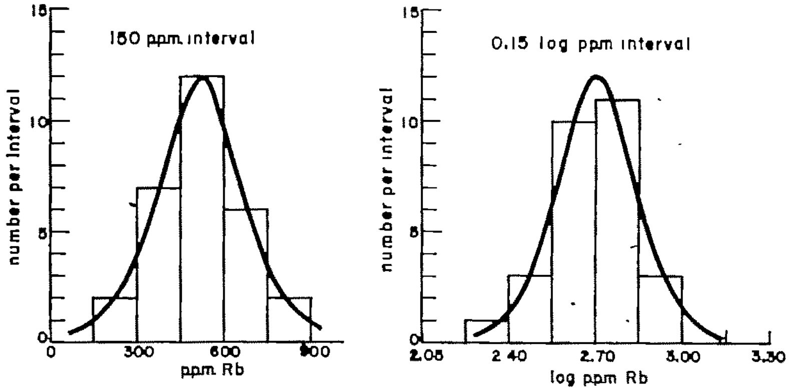

Fig. 2. Rubidium in New England granite. Both the rubidium content and its logarithm appear normally distributed. Dispersion is small ($\sigma = 28$ per cent)

A full discussion will be published elsewhere.

Synthesis of Sucrose by a Plant Enzyme Extract

AN enzyme capable of sucrose synthesis has been epared from dried cells of the bacterium *Pseudo-onas saccharophila*[1]. This enzyme, sucrose phos-orylase, catalyses the reversible reaction

$$\begin{matrix}\text{ucose-1-}\\ \text{hosphate}\end{matrix} + \text{fructose} \rightleftharpoons \text{sucrose} + \begin{matrix}\text{inorganic}\\ \text{phosphate.}\end{matrix}$$

he equilibrium constant for this reaction

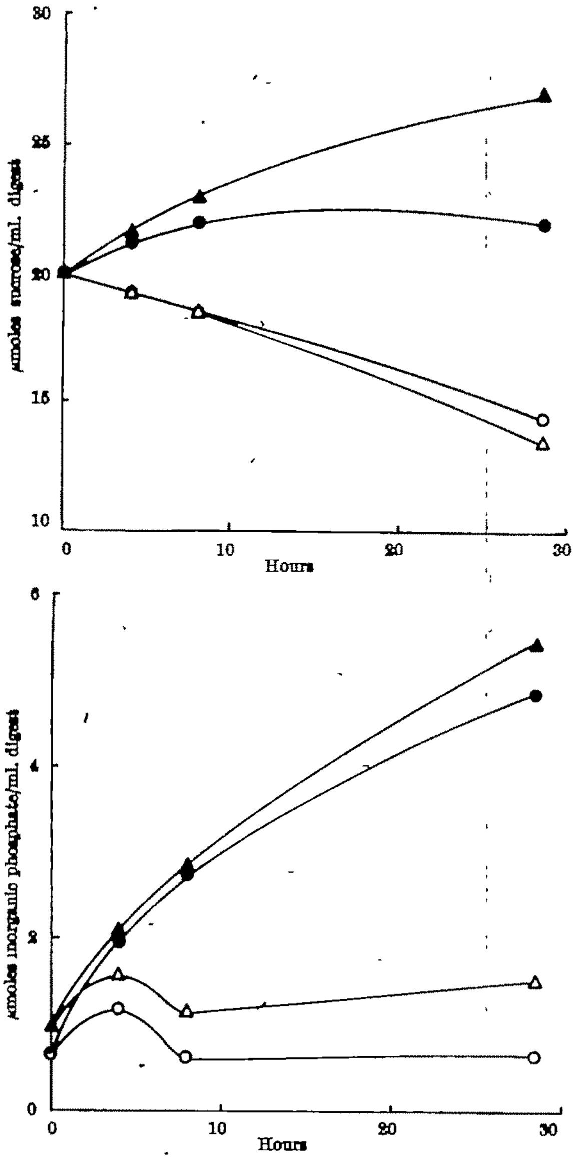
$$\left(K = \frac{[\text{sucrose}]\,[\text{inorganic phosphate}]}{[\text{glucose-1-phosphate}]\,[\text{fructose}]}\right)$$

0·05 at pH 6·6 and 30° C.[2]. Attempts to demon-rate a sucrose phosphorylase in various plant tissue tracts have been unsuccessful[3].

In the present investigation it was found that when ude extracts from peas were incubated with a mix-re of glucose-1-phosphate and fructose there was a beration of inorganic orthophosphate and a synthesis a sugar possessing the properties of sucrose. This gar was indistinguishable from sucrose when plied to paper chromatograms and developed in e following solvents: n-propyl alcohol (80 vol.)/ater (15 vol.)/ammonia (5 vol.), n-butyl alcohol 0 vol.)/acetic acid (10 vol.)/water (50 vol.), n-butyl cohol (50 vol.)/ethyl alcohol (5 vol.)/water (10 vol.) nd ethyl acetate (57 vol.)/n-propyl alcohol (32 ol.)/water (13 vol.). The substance reacted strongly benzidine-trichloracetic acid spray[4] and to naphtho-esorcinol-phosphoric acid spray[5], indicating that it ontained both aldose and ketose components. The ugar, when eluted from chromatograms, did not educe Fehling's solution but was completely hydro-sed by 0·025 N hydrochloric acid within four inutes at 100° C. and was then strongly reducing. he hydrolysed material, when applied to paper hromatograms and developed in each of the four olvents previously mentioned, was shown to contain wo components which ran in positions identical with hose occupied by glucose and fructose and which ave the reactions expected from these monosacchar-les when sprayed with the benzidine and naphtho-esorcinol reagents.

The effects of the addition of fructose and of lucose-1-phosphate on the sucrose and inorganic hosphate content of enzymic digests containing the ude pea extract are shown in the accompanying gure. Sucrose was determined by estimating the uctose component in the sucrose separated on aper chromatograms. The crude pea extract con-ained sucrose. Without addition of substrate, the ucrose concentration in the enzymic digest decreased, nd this decrease was slightly greater when glucose-1-hosphate was added. When fructose alone was dded there was a small increase in sucrose (the crude ea extract contained significant amounts of hexose hosphates). On the addition of both fructose and lucose-1-phosphate, the sucrose content was con-derably increased. Fructose also produced a libera-ion of inorganic phosphate in digests with and with-ut glucose-1-phosphate.

It will be seen from the data presented in the figure hat the addition of glucose-1-phosphate increased he difference in sucrose concentration between nzymic digests with and without fructose from 7·5 13·5 µmoles/ml. after twenty-eight hours but ecreased the difference in inorganic phosphate con-entration between such digests from 4·2 to 3·9



The effects of glucose-1-phosphate and fructose on sucrose and inorganic phosphate concentration in enzymic digests containing the crude pea extract. Digest: crude pea extract, 2 ml.; total volume, 4 ml. pH 6·9, 25° C. Additions: glucose-1-phosphate, 0·013 M; fructose, 0·066 M. ○, No addition; ●, fructose; △, glucose-1-phosphate; ▲, glucose-1-phosphate plus fructose

µmoles/ml. It was further found that increasing the initial concentration of glucose-1-phosphate in the enzymic digests from 0·013 M to 0·033 M increased the liberation of inorganic phosphate on the addition of fructose but depressed the formation of sucrose. It appears that there is no direct relationship between the amounts of sucrose formed and inorganic phosphate liberated by the crude pea extract.

It was found that while the concentration of sucrose was increasing in the enzymic digest containing both glucose-1-phosphate and fructose, the value of the expression

$$\frac{[\text{sucrose}]\quad[\text{inorganic phosphate}]}{[\text{glucose-1-phosphate}]\quad[\text{fructose}]}$$

increased from approximately 2·0 at eight hours to approximately 2·8 at twenty-eight hours. These values were minimal, as will be shown in a subsequent publication. The conclusion is that a mechanism of sucrose synthesis was operating which was different from the simple reaction between glucose-1-phosphate and fructose shown in the equation. This is in agreement with the results of previous workers using intact leaves[6] and algæ[7].

The sucrose-forming activity of the crude pea extract was destroyed by heating for three minutes at 100° C. The activity remained in the supernatant when the crude pea extract was centrifuged at 20,000 *g* for thirty minutes. The extract possessed negligible invertase activity. Sucrose synthesis was completely inhibited by 1×10^{-4} *M* iodoacetate and $6{\cdot}5 \times 10^{-3}$ *M* fluoride.

A detailed account of this work will be presented elsewhere. It is proposed to publish shortly results of experiments using a purified enzyme preparation.

I wish to express my indebtedness to Prof. C. S. Hanes and Dr. L. W. Mapson.

Financial support was provided by the Australian Commonwealth Scientific and Industrial Research Organization, and the work was continued during the tenure of a Broodbank Fellowship of the University of Cambridge.

Autoradiographic Detection of Sulphur-35 Synthesis by the Mucous Neck Cells of the Rat's Stomach

TINCTORIAL and histochemical differences between the surface cells of the stomach and the mucous neck cells described by Bensley are now classical knowledge[1]; moreover, physiological and biochemical differences between dissolved mucin and visible mucin have been established[2]. The stomach secretion has also been found to contain a mucoprotein, the polysaccharide moiety of which was identified as mucoitin disulphuric acid[3,4].

While studying the formation of the organic matrix of bones and teeth by autoradiographic mapping, some interesting pictures of the stomach were revealed after introduction of radiosulphur. Rats of 10 days of age were injected subcutaneously with a tracer dose of sulphur-35 separated isotope in the form of weak sulphuric acid, and they were sacrificed at various intervals thereafter. The tissues were fixed in a mixture of 95 per cent ethanol and neutral formaldehyde (3/1). After routine histological treatment, sections were cut and coated with fluid photographic emulsion to obtain autoradiographs by the inversion technique[5].

In animals sacrificed one hour after the injection of sulphur-35, the stomach wall showed a fairly high Geiger–Müller count compared to other soft tissues. Autoradiographs exposed for a few days (Fig. 1) have revealed that there was a specific localization of the radiosulphur in the glandular portion of this organ, at the level of the neck of the glands. The surfa epithelium as well as the distal portion of the glan showed no autoradiographic image. In anima sacrificed 48 hr. after the introduction of tracer, n autoradiographic picture was visible over the mucosa but streaks of mucin mixed with the chyme of th cavity exhibited radioactivity.

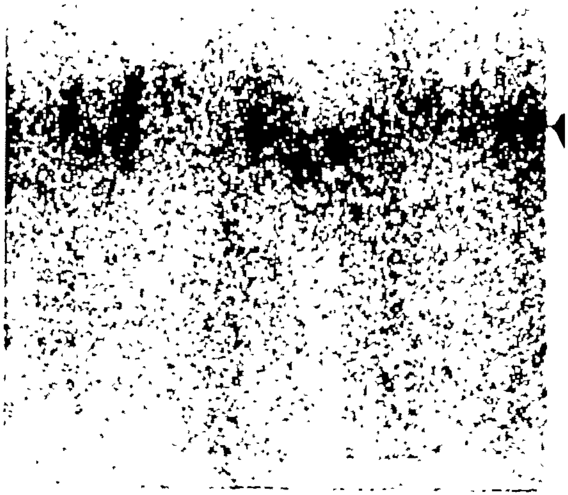

Fig. 1. Sulphur-35 autoradiograph of a portion of the mucosa of the glandular stomach in a 10-day old rat, showing the presence of radiosulphur in the mucous neck cells 1 hr. after a subcutaneous injection. × 332

These experiments indicate that there is a chemic difference between the secretion of the surface cell and that of the mucous neck cells. These have th ability to synthesize rapidly an organic substanc containing sulphur and retained by alcohol–formaldehyde fixation. Boström and Odeblad[6] have recentl demonstrated that, following an injection of radio sulphate, the uptake of sulphur-35 is highest i structures containing mucopolysaccharides. It is thu reasonable to conclude that the mucous neck cell produce a mucoprotein containing a sulphomucopolysaccharide, and that in comparable circumstance this substance is not present in the surface cells. Th product of the mucous neck cells is totally excrete at the end of two days, and it is found in the chym where it retains its identity after histological fixation Work is in progress to establish comparisons between the various portions of the stomach and other region of the gastro-intestinal tract.

I am indebted to Mrs. Cécile Bélanger for technica collaboration, and to the Medical Division of th National Research Council of Canada for a grant in-aid. The radioactive material was provided by Atomic Energy of Canada, Ltd.

Effect of Hydroquinone on Mitosis

In a previous communication, Parmentier and Dustin[1] reported a mitotic anomaly in the mouse ntestine produced by hydroquinone. The characteristic feature of this was the so-called 'three-group metaphase', comprising a normal metaphase plate with additional chromosome particles or groups at each pole of the spindle. One of the authors afterwards described the same phenomenon in the intestine nd bone marrow of the golden hamster[2]. According o the latter, characteristic 'three-group metaphases' may also be produced in the rat, whereas "the uinea pig, the chick and chick fibroblast cultures were not responsive as regards this effect".

We wish to report analogous effects produced by ydroquinone *in vitro* in chick fibroblasts, and *in vivo* n the liver, the bone marrow and the cornea of the at.

Chick fibroblast cultures (third passage) were nmersed in a solution of 1 in 10^{-6} hydroquinone in inger's solution and incubated for one hour, or nmersed in a solution of 1 in 10^{-7} and incubated or 2 hr. The whole cultures were then fixed and tained with Giemsa's stain. Typical hydroquinone mitoses could be observed (Fig. 1).

In rats treated intraperitoneally with the same oses as used by Parmentier and Dustin, we observed, hr. after treatment, mitoses in the liver, some howing the characteristic features (Fig. 2) as decribed by these authors. In the bone marrow the hree-group mitoses' were found in the white precursors (Fig. 3), whereas the red precursors showed often very marked karyorrhexis. As in the cultures. nly a certain number of mitoses showed these hanges, others being normal. On the whole, mitoses were not very numerous in the bone marrow after reatment with hydroquinone.

In the cornea of the rat the same effect was seen hr. after instillation of one drop of a 5 per cent olution of hydroquinone into the conjunctival sac, r after intraperitoneal injection of hydroquinone in oses mentioned above.

These observations, added to those of Parmentier nd Dustin, show that hydroquinone had a general effect on various tissues, manifested by characteristic hanges in the morphological aspect of mitosis. The xperiments on chick fibroblasts *in vitro* and on the cornea of the rat *in vivo* further suggest that the drug acts directly on the cell.

Application of Nigrosine to the Study of the Salivary Chromosomes

In this work, an alcohol-soluble nigrosine (Edward Gurr) was used, and the stain prepared by Rosen's method[1,2]. The scheme of treatment followed for staining the salivary chromosomes of *Drosophila* is as follows. (1) Dissection in 45 per cent acetic acid. (2) Treatment with freshly prepared alcoholic hydrochloric acid during 1–2 min., keeping the glands well covered. (3) The specimen is washed two or three times carefully with distilled water, and a big drop of water is left on the material for 5 min. (4) Drain thoroughly and carefully. (5) Add a drop of stain and put on a cover slip, without squashing. (6) After 10–15 min., squash under blotting paper and immediately put a big drop of glycerine on one edge of the cover slip. (7) The preparation can be studied at once; but after 24 hr., the glycerine having penetrated the specimen thoroughly, it is convenient to get rid of excess liquid and make a wax border. Preparations thus obtained last a long time if handled carefully.

With this method the salivary chromosomes are strongly and specifically coloured. Only the outer bands are dyed, except in the heterochromatin regions. But when the preparation is ageing, the interbands become faintly coloured, and the same happens with the cytoplasm.

The greatest interest of this method is in its peculiar mode of placing the chromocentre. In every case studied the chromocentre shows itself as a differentiated and constant structure for each species. Four structural elements can be distinguished: (1) faint

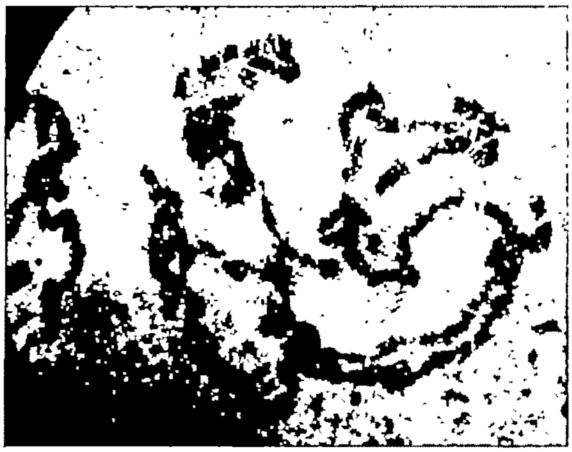

Fig. 1

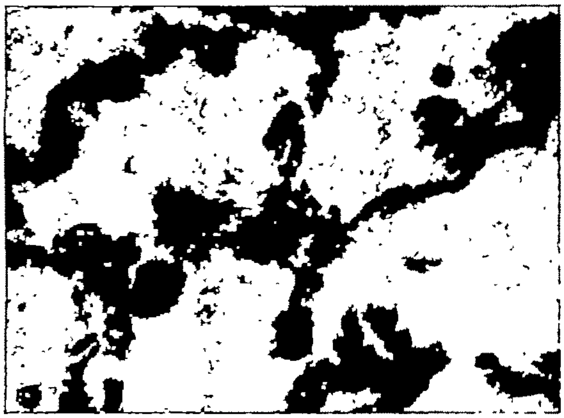

Fig. 2

heterochromatin with chromomeres; (2) faint heterochromatin without chromomeres; (3) compact heterochromatin with vesicle chromomeres; (4) heterochromatin with chromomeres arranged in more or less regular bands. Between (1) and (2) there is a whole series of gradations. In the material studied, these elements occur as follows: *D. funebris* (1), *D. immigrans* (1, 3, 4), *D. mercatorum* (1), *D. melanogaster* (2, 4) and *D. simulans* (2, 4).

The accompanying photographs are of the salivary nucleus of *D. funebris*, Fig. 2 being an enlarged view of the region of the chromocentre.

Action of Duck's Egg White Ovomucoid on Tryptic Hydrolysis of Casein *In vitro*

IT has been reported by Dikshit and Patwardhan[1] that duck's egg white has a low efficiency for promotion of growth in rats when compared with hen's egg white. On autoclaving, the nutritive value of duck's egg white showed remarkable improvement[2]. *In vitro* digestion of raw egg whites with trypsin indicated that the rate of hydrolysis of duck's egg white was much slower than that of hen's egg whit Ovomucoid prepared from duck's egg white accor ing to the method of Lineweaver and Murra exhibited both antitryptic activity and suppressio of growth in rats when added to their diets. Th possibility of interference by the ovomucoid with th enzymatic release of one or more essential amin acids by trypsin was envisaged. This communicatio gives the results of a preliminary investigation o the hydrolysis of casein by trypsin in presence the purified duck's egg white ovomucoid, whic showed that the liberation of several essenti amino-acids was inhibited.

2,500 mgm. of casein (lactic casein, 13·5 per cen nitrogen) in a phosphate buffer of *p*H 7·6 wa digested with 100 mgm. of trypsin (Nutrition Biochemicals) at 37° C. One such batch served a the control, and to another 25 mgm. of duck's eg white ovomucoid was added. Aliquots were with drawn at the end of 24 and 120 hr.; trypsin wa inactivated by heating in boiling water for 15 mi Undigested protein was precipitated by adjusting th *p*H to 4·2 with a few drops of glacial acetic aci In duplicate aliquots withdrawn at the same tim total amino-nitrogen was determined by form titration.

In the protein-free filtrate all the essential amino acids except methionine were estimated by micro biological methods as described by Dunn *et al.*[4] methionine was estimated by the colorimetric metho of McCarthy and Sullivan[5]. The results are given i Table 1.

Table 1. ESSENTIAL AMINO-ACIDS LIBERATED FROM CASEIN B TRYPSIN WITH AND WITHOUT DUCK'S EGG WHITE OVOMUCOID

Amino-acid	Amino-acid liberated (mgm.) after: 24 hr. Control	Exp.	Percentage deficiency in exp.	120 hr. Control	Exp.	Percentage deficiency in exp.
Arginine	105·0	95·0	9·5	105·0	100·0	4·8
Histidine	52·0	25·0	51·9	61·0	42·0	31·2
isoLeucine	103·9	79·2	23·8	107·9	84·2	22·0
Leucine	284·5	199·1	30·0	289·7	208·6	28·0
Lysine	106·5	52·5	50·7	112·5	77·5	31·1
Methionine	77·0	77·0	nil	77·6	75·2	3·1
Phenylalanine	135·0	123·4	8·6	136·7	131·7	3·7
Threonine	77·2	38·7	40·9	77·2	41·3	46·5
Tryptophan	40·0	35·0	12·5	40·0	40·0	nil
Valine	100·0	26·5	73·5	111·0	53·0	52·2

The total amino-nitrogen liberated was 99·4 an 113·0 mgm. in 24 and 120 hr. respectively in th control. In the presence of the ovomucoid, th corresponding values were 67·4 and 85·8 mgm respectively, indicating that the presence of ovomucoid inhibited the release of amino-acids. Th percentage deficiency of the liberated individua amino-acids in the presence of ovomucoid calculate over the amounts released in the control is given i columns 4 and 7. It can be seen from the table tha enzymatic release of histidine, lysine, threonine an valine was highly inhibited; the inhibition in th liberation of *iso*leucine, leucine and tryptophan (afte 24 hr.) was moderate. On the other hand, liberatio of arginine, methionine, phenylalanine and tryptopha (after 120 hr.) was not significantly retarded.

From these results, it is evident that the duck' egg white ovomucoid interferes with the *in vitr* release of certain essential amino-acids by trypsin from which it would be reasonable to conclude tha the presence of ovomucoid may create an unbalanc f amino-acids in the body owing to its selective hibition of the liberation of amino-acids in the testines. Geiger[6] suggested that the availability f all the essential amino-acids from a protein in efinite proportions in the intestines determines to very large extent its effective utilization for tissue rotein synthesis. The results of this investigation ould appear to support Geiger's hypothesis and pro-de an explanation for the low nutritive value of uck's egg white.

Further work is in progress, and a detailed report ill be published elsewhere. We are grateful to Dr. . N. Patwardhan, director, Nutrition Research aboratories, for his interest and advice in this ivestigation.

Thelytokous Parthenogenesis for Four Generations in the Desert Locust (*Schistocerca gregaria* Forsk) (Acrididæ)

PARTHENOGENESIS occurs naturally in several rders of insects, and can conveniently be classified ccording to the sex of the offspring which develop rom the unfertilized egg: (1) arrhenotoky—males nly (fertilized eggs give rise to females); (2) thely-oky—females only; (3) amphitoky—both sexes.

It is the second type which I believe occurs exlusively in the desert locust. Parthenogenesis of he thelytokous type has been recorded for many Acrididæ; for example, Plotnikov[1] for the migratory ocust (*Locusta migratoria*), Slifer and King[2,3] for nany species of grasshoppers. Nabours[4] with a ratio f 4,470 females to 7 males, and Nabours and Foster[5] ecording all females, with rare exceptions, can be ncluded in this type of parthenogenesis. Faure[6] unfortunately did not sex his brown locusts (*Locustana pardalina*), which were produced parthenogenetically. Husain and Mathur[7], working with *Schistocerca gregaria*, report several cases (four egg-pods) of parthenogenetic eggs; hoppers hatched from two egg-pods, and Husain and Mathur state that they were able to rear hoppers to the adult stage but failed to get a second generation. They found that their parthenogenetically produced locusts were males and females in equal numbers, that is, amphitokous parthenogenesis. These results of Husain and Mathur are entirely contrary to my findings, as all my parthenogenetically produced *Schistocerca gregaria* have been females.

Table 3. RATE OF DEVELOPMENT AND PERCENTAGE OF PARTHENOGENETICALLY PRODUCED HOPPERS REACHING THE ADULT STAGE

How produced	No. of hoppers at start of exp.	Average length of hopper life (in days)	Total number of adults	Sex of adults		% of hoppers which reach adult stage
				Males	Females	
F_1 Parthenogenetically	55*	30·1	18	—	18	32·7
F_2 "	52*	28·9	22	—	22	42·3
F_3 "	21*	29·5	11	—	11	41·7
F_4 "	17*	Experiment still in progress				
Controls Sexually	232	28·6	121	56	65	52·2

* These figures do not represent all hoppers produced parthenogenetically as many, not included here, were used for cytological work.

Although all my locusts have been reared in cages, the parthenogenesis can still be regarded as 'natural' because they have been kept at a constant temperature of 90° F. (32·2° C.) and a relative humidity varying from approximately 60 to 70 per cent. These conditions have been shown by me[8] to be suitable for this species of locust. (A few experiments have now been carried out exposing the eggs to a temperature of 41° F. (5° C.) for 5 hr. within 24 hr. of being deposited, but this does not seem to affect the percentage hatched in any way.) The original females (Table 1), which were sexually produced, were separated from males while still in the hopper stage and housed in a separate insectary, so that there could be no possibility of copulation having taken place. Up to the date of writing, it has been possible to produce four successive generations of females; and these females have laid a total of 170 egg-pods.

Table 1. RATE OF SEXUAL MATURATION, LENGTH OF ADULT LIFE, AND FECUNDITY OF PARTHENOGENETIC FEMALES

How produced	No. of adults		First egg-pod (days)	Last egg-pod (days)	Av. egg-pods per female	Female days per egg-pod	Length of adult life (days)		
	♂♂	♀♀					Av.	Min.	Max.
Sexually*	0	10	35	320	5·4	33·7	182·1	97	328
F_1 Parthenogenetically	0	8	37	211	3·1	36·9	130·5	33	226
F_2 "	0	15	31	Experiment still in progress					
F_3 "	0	10	30	" " " "					
Controls Sexually	24	30	22	102	3·5	18·1	63·5	26	108

* This experiment has been repeated and a second series of parthenogenetically produced locusts started.

Table 2. NUMBER OF EGGS PER EGG-POD, NUMBER WHICH HATCHED, AND INCUBATION PERIOD OF PARTHENOGENETICALLY PRODUCED EGGS

How produced	No. of egg-pods tested	Eggs per egg-pod			No. of hoppers which hatched per egg-pod			Eggs which hatched (per cent)	Incubation period (days)
		Av.	Min.	Max.	Av.	Min.	Max		
F_1 Parthenogenetically	17	42·8	33	55	10·1	1	35	23·6	14·2
F_2 "	16	40·1	29	51	10·6	1	30	26·3	14·7
F_3 "	7	47·0	24	60	10·3	4	21	25·5	14·8
F_4 "	2	41·3	31	55	11·5	3	20	27·8	14·5
Controls Sexually	59	47·2	28	64	35·5	8	62	75·2	14·1

It can be seen from Table 1 that the interval between the emergence of the adults and the laying of the first egg-pod was much longer for all parthenogenetic generations (30–37 days) than for the controls (22 days). This suggests that either the presence of males in the cages, or copulation, has a stimulating effect on the rate of sexual maturation of the females. Likewise, more days per egg-pod (33·7–36·9) were required by the parthenogenetic females than by the controls (18·1 days). Notwithstanding this increase in the time required to produce an egg-pod, the total number of egg-pods per female was not affected, because the females producing parthenogenetically lived much longer than the controls producing fertilized eggs. This becomes even more obvious when it is noted that there is no significant difference in the incubation period (Table 2) or in the time required for hopper development (Table 3). The difference in the length of adult life of the two groups is so striking that it raises a very important physiological problem which obviously requires further study.

The average number of egg-pods produced parthenogenetically (also eggs per egg-pod) compares favourably with the number produced sexually, but the average hatch (Table 2) per egg-pod has been very much lower in all generations. So far the hatch for parthenogenetically produced egg-pods has varied from 10·1 to 11·5, as against 35·5 for sexually produced eggs. Despite this reduction in fertility, the actual reproductive potential is not so much reduced, because all the parthenogenetically produced offspring in all generations have been females and therefore potential egg producers. Unlike the findings of some other workers[3,4] on grasshoppers, my results for locusts show that there is only a slight (approximately 10 per cent) reduction in the percentage of parthenogenetically produced hoppers which reach the adult stage (Table 3).

Bugini[10] says that in some silkworms the parthenogenetic tendency is transmitted and accentuated by heredity; but, unless a reduction from 37 to 30 days (in the F_2 generation) in the time required to reach sexual maturation and oviposit can be regarded as significant, there is no evidence to show that parthenogenesis is being accentuated and transmitted in *Schistocerca gregaria*.

Since I have been successful in rearing four generations of this locust parthenogenetically, I feel that there is a possibility that thelytokous parthenogenesis may play a part in the preservation of the species when isolated in the solitary phase.

I would like to express my thanks to the Anti-Locust Research Centre, London, S.W.7, for the original stock of locusts.

Weight Relationships among Animal Viruses

THE most certain estimates of particle size in th case of animal viruses are probably those based ultra-centrifugation or diffusion measurements coupl with biological assay. Apart from exceptional cas when material of unusual high titre is available, on a combination of the biological with the physic method can ensure that the physical values refer the particles having the biological properties studie Electron microscopy, however, to which this saf guard cannot rigidly be applied, can undoubtedl provide excellent confirmatory evidence.

All the results for particle size obtained by the methods, which relate to the smaller animal virus and which are known to me, are assembled in Table Some of the measurements have been made recent in this laboratory and details will be publishe later.

It will be seen from the table that not only do th viruses fall into three groups having sedimentatio constants respectively of about 70, 170 and 450 but also that the range of sedimentation constan distribution within each group is remarkably smal

At this stage no attempt will be made to grou the larger viruses, as their sizes are usually given range which is too wide; for example, influenz virus has been given a range of 76–120 mμ. Equin encephalomyelitis cannot be placed with certainty the third group with horse-sickness, etc. This viru is known to contain 40 per cent lipoid, which mus render accurate estimation of its size difficult.

Attention is directed to the fact that the sed mentation constants of lumpy skin disease, *MEF* yellow fever, rift valley fever and African horse sickness virus have been determined by the sam technique.

Assuming on the basis of published electron micrographs that animal viruses are all approximatel spherical, their volumes—and consequently thei particle weights—will be proportional to the cub of the diameter. The average diameter of each grou of viruses is given in the fourth column of Table and the corresponding volumes in mμ^3 in the fift column. These volumes are approximately in th ratio 1 : 4 : 16, suggesting that viruses in each grou may be built from the same number of sub-units which may differ in composition but have approximately equal volumes.

A clue to the possible nature of the sub-units wa provided by Hoyle, Reed and Astbury[1], who showe that the influenza virus may be broken up by treatment with ether into hæmagglutinating and complement-fixing but non-infectious sub-units, approximately 12 mμ in diameter. Similar complement-fixin non-infectious sub-units have now been separated i this laboratory from preparations of rabies virus[2] The diameter of the rabies sub-units has been estimate by diffusion measurements to be 11–13 mμ.

Calculations from the results in Tables 1 and 2 wil show that the volumes of the smallest virus particle are almost exactly four times that of the sub-unit (the complement-fixing antigens) of influenza virus and it is therefore tempting to conclude that sub-units of this size form the basis of virus structure.

Assuming that the group with the smallest diameter, lumpy skin disease and foot-and-mouth disease, does contain four units, then the corresponding number of units in the others is shown in column 7, and the theoretical diameter in column 8.

Table 1. Sedimentation Constants and Relative Particle Weight of the Smallest Viruses

Virus particle	S (Svedbergs)	Average S	Diam. (mμ)	d^3 (in mμ³)	n × 7,300	Theor. No. of subunits	Theor d (in mμ)
Foot-and-mouth disease	70 (refs. 3 and 4)	70	19·4	7,300	1	4	19 4
Lumpy skin disease	70 (ref. 5)						
Theiler's virus	160–170 (ref. 6)	160	30·44	28,220	3 78	16	30 78
Coxsackie virus	167 (ref. 7)						
Poliomyelitis *MEF*$_1$	163–180 (ref. 8)						
Yellow fever	167 (ref. 9)						
Horse-sickness, neurotropic	466–470 (ref. 10)	440	49 5	121,300	16·6	64	48 9
Rift Valley fever, viscerotropic	412–476 (ref. 9)						

ble 2. Particle Diameters of the Soluble Antigens of Influenza and Rabies
determined by electron microscopy; *d*, determined by diffusion measurements

Soluble antigen of:	Particle size d (in mμ)	d^3 (in mμ³)
Influenza e (ref. 1)	12	1,728
Rabies d (ref 2)	11–13	

I wish to thank Prof. M. van den Ende for his terest in this work, and Drs. G. Selzer and T. H. ead for many helpful discussions in the preparation this manuscript. Additional funds were obtained om the Nkane-Kitwe and Chingola Poliomyelitis esearch funds.

A Method of Isolating Soft-rotting Bacteria from Soils

In the course of work carried out at the North of Scotland College of Agriculture on bacterial soft rot of potatoes (*Bacterium carotovorum* (L. R. Jones) Lehmann and Neumann), it was found difficult to solate the causal organism from naturally infected ubers if infection had occurred through wounds. n most cases only secondary saprophytic bacteria ould be isolated. Where infection had occurred through lenticels, soft-rotting bacteria were readily solated. This was confirmed in laboratory experiments.

As a result, a method was devised for isolating oft-rotting bacteria from soils. 5 gm. of the soil to be tested was shaken up with 250 ml. sterile water. Eight immature potato tubers of the variety Ulster Chieftain, freshly dug and free from surface wounds, were washed in tap water, dipped in methylated spirit, surface-sterilized by immersion for 30 min. in a 1 : 20 solution of sodium hypochlorite dairy disinfectant and then washed for 5 min. in sterile water. Four of the tubers were placed in the soil suspension for 5 min. and four were placed in sterile water as controls. All tubers were then incubated separately for 48 hr. in small glass jars at a relative humidity of 100 per cent and a temperature of 26° C. To isolate soft-rotting bacteria, a visibly infected tuber was washed with tap water and cut lengthwise with a sterile scalpel. A cut was then made in the healthy tissue of the exposed surface so that the half-tuber could be split across to expose a rotted area. This course was taken to avoid contamination by the scalpel. A small piece of rotted tissue was taken from the extremity of the rot, transferred to sterile water in a test-tube and left for thirty minutes. The bacterial suspension so obtained was streaked on to nutrient agar and the bacteria from Gram-negative colonies were isolated. Each isolate was inoculated into freshly cut sterile slices of potato tuber to determine its pathogenicity.

Twenty soil samples, obtained from the Macaulay Institute for Soil Research, were tested by this method for the presence of soft-rotting bacteria. The samples were taken from different types of soil in the north of Scotland and at different stages in the normal seven-course rotation. In every case soft-rots developed in all the inoculated tubers as a result of lenticel infections, and pathogenic bacteria were isolated. The controls remained healthy. This method proved quicker and more reliable than that described by Leach[1], in which a soil suspension was inoculated into potato tubers by the 'hole and plug' method.

The Autumn Flush of *Drosophila* (Diptera)

During routine trapping with apple bait in two mainly deciduous woods at Liberton, near Edinburgh in 1950, a sudden large increase in numbers of adult *Drosophila* was caught early in November. Two traps on the ground and exposed during October 31–November 7, 1950, gave the usual few adults, namely, 52 (38 *D. subobscura*, 7 *D. obscura*, 1♂ *D. silvestris* n.sp., 1♀ *D. tristis*, 2 *D. phalerata*, 3 *D. funebris*), whereas the two replacements exposed November 7–14, 1950, caught 970 *Drosophila* (867 *D. subobscura*, 56 *D. obscura*, 5♀ *D. silvestris*, 25 *D. tristis*, 2 *D. ambigua*, 5 *D. phalerata*, 9 *D. funebris*, 1♀ *D. cameraria*) (sex signs are given when only one sex occurred). The increase was obviously due mainly to one species, *D. subobscura*. Similar large numbers were obtained at other sites at the same time. When next exposed, December 6–12, 1950, there were 416 *Drosophila* in the two traps (320 of the 325 examined being *D. subobscura*). Trapping continued until January 24, 1951, and again from February 7, 1951; but up to February 22 flies were very few or absent, doubtless because the temperature remained mostly below 40° F. (4·4° C.), the approximate threshold temperature of activity for *D. subobscura*, the hardiest species. During the period February 22–March 1, 1951, however, the two traps caught 309 flies (298 *D. subobscura*, 3♂ *D. obscura*, 7 *D. cameraria* and 1♂ *Parascaptomyza disticha*), and large numbers again occurred during March 1–3, 1951 (261 *D. subobscura*, 1♂ *D. obscura*, 2♂ *D. tristis* and 4 *D. cameraria*).

The trapping was repeated at the same two sites in 1951, starting on October 23, 1951, with the following results:

	Oct. 23–30, 1951	Oct. 30–Nov. 6, 1951	Nov. 6–13, 1951	Nov. 13–20, 1951	Nov. 20–27, 1951
D. subobscura	20	12	60	1,061	1♂
D. obscura	11♀	15	8	48	—
D. silvestris	40	34	8	14	—
D. tristis	1♀	—	1♂	12	—
D. ambigua	—	—	—	1♀	—
D. phalerata	—	2	—	2	—
D. funebris	—	1♀	2	1♀	—
Total	72	64	79	1,139	1

The next two weeks yielded only 14 *D. subobscura* and nil flies respectively; but with the two traps out during December 14–21, 1951, there was a second flush of 1,496 *Drosophila* (1,472 *D. subobscura*, 15 *D. obscura*, 7 *D. tristis*, 2 *D. cameraria*). The traps were out until March 7, 1952, being renewed every seven days, but there was no further flush, although higher numbers than usual were obtained during the three weeks from February 15, 1952 (186, 209 and 119 *Drosophila* respectively, all being *D. subobscura* except 7 *D. obscura* and 2♀ *D. tristis*).

During 1952 traps were out at various heights in trees and at their bases at Dalkeith. A flush was experienced with traps exposed during October 3–10, 1952 (previous traps out every other week, the last during September 19–26). Traps were then out continuously from October 17, 1952, and a second flush occurred within the period December 5–12, 1952.

It thus appears that the autumn flush is an annual phenomenon in the Edinburgh district. Its causes and whether it occurs over the whole week or over a more restricted period can only be solved by day-to-day observations, which cannot at present be undertaken, owing to pressure of other work. The cause of the initial flush appears to be independent of temperature and of leaf-fall of trees; but the repeat flushes are probably a result of higher temperatures after cold periods. The occurrence of such sudden temporary fluctuations in numbers suggests that the population dynamics of this species are not straightforward, and that caution is necessary in arriving at any opinion as to the effective population size, in Wright's sense[1].

Observations on the Anal Papillæ of *Cule* (*culex*) *fatigans* Wiedemann

THE length and shape of the anal papillæ mosquito larvæ, although a useful aid to oth diagnostic factors, have never been a critical specif factor. Kettle[1] has shown that the length of th anal papillæ of *Anopheles sergenti* Theobald dependent on the saline content of the larval habit and that small changes in salinity may produce large difference in the length of the anal papill A similar observation has been noted in Mauritiu where larvæ of *Culex fatigans* Wd. show variation length of the anal papillæ, according to the salinit of their habitat. This variation may be so gre and so striking as to cause some doubt as to th immediate identification of the larvæ.

Fourth-stage larvæ of *C. fatigans* were foun breeding profusely in a small tin, partially filled wit foul-smelling water and rotting leaf debris. Th extremely long, lanceolate, anal papillæ were whit in colour. A more than cursory examination we needed to establish these larvæ as those of *C. fatigan* The length of the longer pair of anal papillæ and th siphonal index were estimated; the salinity of th water was calculated. The results obtained wer compared with a similar set of results obtained fro larvæ breeding in a small concrete tank.

Habitat	Water	*p*H	Salinity (sod. chloride gm./L.)	Average length of papillæ	Siphonal index
Tin can	Dark brown, foul	8·5	0·40	8·0 mm.	3·8–4·2
Concrete tank	Clear	8·0	1·04	3·8 mm.	3·6–4·0

The great increase in length of the anal papill may be directly due to the low concentration o halides in the larval habitat; but it must not b overlooked that life in a small container (tin can may invoke other responses which would lead to th elongation of the anal papillæ.

Fluorine in the Human Skeleton

IN recent chemical tests carried out on the Piltdow skull, the accurate determination of fluorine was o decisive importance. It may therefore be of interes to mention that the discovery of fluorine in th human skeleton has been attributed[1] to Arthu Connell, first professor of chemistry in the Universit of St. Andrews (1840–62). Further, to quote fro a publication of 1864, "as an example of his nicety as an analyst we may refer to his determination o the constituents of Greenockite from a single grain of that mineral"[2].

FORTHCOMING EVENTS

Monday, December 21

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, W.7), at 5 p.m.—Prof. Alan Ross: "Ohthere's Northern Voyage: wenas and Lakes".

Tuesday, December 22

INSTITUTE OF FUEL (at the Institution of Mechanical Engineers, torey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. E. Montagnon and Mr. A. L. Rockley: "The Festival Hall Heat ump".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or efore the dates mentioned:

ASSISTANT EXPERIMENTAL OFFICER (preferably with pass degree r A.R.I.C.), to do chemical analyses associated with grassland and ther research—The Secretary, The Hannah Dairy Research Institute, irkhill, Ayr (December 26).

EXPERIMENTAL or ASSISTANT EXPERIMENTAL OFFICER (with at east II S.C. (science) or equivalent), at the Atomic Energy Research stablishment, Harwell, to work on problems associated with fundamental physical and metallurgical studies related to the design of fuel or nuclear reactors—The Establishment Officer, Atomic Energy esearch Establishment, Harwell, quoting 2/103/19 (December 26).

PRINCIPAL or SENIOR SCIENTIFIC OFFICER (with an honours degree n engineering, physics or mathematics, and some engineering experience) at the Atomic Energy Research Establishment, Harwell, for undamental studies of nuclear reactor design involving basic engineering investigations in conjunction with nuclear physics aspects—The stablishment Officer, A.E.R.E., Harwell, Berks, quoting 2/103/23 December 26).

CARTOGRAPHER (preferably geography graduate) FOR THE DEPARTMENT OF GEOGRAPHY—The Secretary of University Court, The niversity, Glasgow (December 30).

LECTURER or ASSISTANT LECTURER (with special interest in endocrinology and pharmacology) IN PHYSIOLOGY—The Secretary, Royal eterinary College and Hospital, Royal College Street, London, N.W.1 December 31).

ASSISTANT EXPERIMENTAL OFFICER (with a pass degree or at least he general certificate of education at advanced level), IN THE CHEMISTRY SECTION, to work mainly on the treatment and recording of field xperimental plots—The Secretary, National Vegetable Research tation, Wellesbourne, Warwick (January 1).

MUSEUM ASSISTANT (with a degree, including geology to at least ass standard, and an interest in palæontology) IN THE GEOLOGY DEPARTMENT—The Secretary, University College, Gower Street, London, W.C.1 (January 1).

RESEARCH ASSISTANT (graduate with some research experience) IN THE FLUID MOTION LABORATORY, to carry out experimental research n the aerodynamic noise generated by turbulent flows—The Registrar, The University, Manchester (January 1).

VETERINARY RESEARCH OFFICERS (2) (members of the Royal College of Veterinary Surgeons, and with experience in veterinary research and investigation work) at the Ministry of Agriculture, Northern Ireland—The Director of Establishments, Ministry of Finance, Stormont, Belfast (January 1).

EXPERIMENTAL OFFICER (with a pass degree or higher national certificate in engineering or physics, and with experience in design of experimental equipment and of instruments for measuring metal flow) IN THE DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH, Mechanical Engineering Research Laboratory, East Kilbride, for work on plastic deformation and cutting of metals—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.631/53A (January 2).

SCIENTIFIC OFFICER or SENIOR SCIENTIFIC OFFICER (with first- or second-class honours degree or equivalent in chemistry, biochemistry or an allied subject and preferably with research experience in nutrition) IN THE NUTRITION DEPARTMENT—The Secretary, The Hannah Dairy Research Institute, Kirkhill, Ayr (January 2).

CHAIR OF CIVIL ENGINEERING—The Registrar, University College, Singleton Park, Swansea (January 10).

LECTURER (with honours degree and practical or research experience in either civil or mechanical engineering) IN ENGINEERING—The Secretary, The University, Aberdeen (January 12).

CHAIR OF MINING—The Registrar, The University, Sheffield 10 (January 14).

SCIENTIFIC LIAISON OFFICER (with good degree in physics or chemistry, preferably foreign, and with industrial research experience) with the Pakistan High Commission, London—The Educational Attaché, High Commissioner for Pakistan, 39 Lowndes Square, London, S.W.1 (January 15).

CHEMIST (with good honours degree or equivalent) for analytical investigational work in the Coal Survey Laboratory, Cardiff—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/718 (January 16).

LECTURER (graduate in science or technology, and with a good knowledge of the theory of structures) IN STRUCTURAL ENGINEERING, to undertake research work on structures, and to assist in lecturing and laboratory work in structural engineering—The Registrar, College of Technology, Manchester 1 (January 20).

CHAIR OF GEOGRAPHY—The Registrar, University College, Singleton Park, Swansea (January 30).

LECTURER or ASSISTANT PROFESSOR (with degree of Ph.D., or equivalent, and with special training in embryology and comparative anatomy) OF ZOOLOGY—The Dean, Faculty of Arts and Science, University of Alberta, Edmonton, Canada (February 1).

LECTURER IN APPLIED MATHEMATICS at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Cape Town, February 8).

CHAIR OF BOTANY—The Registrar, University College, Singleton Park, Swansea (February 15).

I.C.I. RESEARCH FELLOWSHIPS IN BIOCHEMISTRY, CHEMISTRY, CHEMOTHERAPY, ENGINEERING, METALLURGY, PHARMACOLOGY PHYSICS or allied subjects—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 31).

ASSISTANT DIRECTOR OF RESEARCH IN THE DEPARTMENT OF ANIMAL PATHOLOGY, University of Cambridge—The Secretary, Faculty of Biology "B", Department of Pathology, Tennis Court Road, Cambridge.

ENGINEER, Grade I (Ref. 510), and an ENGINEER, Grade III (Ref. 511), at the Division of Atomic Energy (Production), for work on major calculations required by design offices concerned with nuclear reactors and factories for producing fissile material—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, quoting appropriate Ref. No.

ENGINEERS and PHYSICISTS, Experimental Officer and Assistant Experimental Officer grades, in Royal Naval Scientific Service Experimental Establishments in the London, Portsmouth, Weymouth and Gloucestershire areas, and Scotland—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.247/52A.

LECTURER or ASSISTANT PROFESSOR (qualified to give advanced instruction in one or both of elasticity and theoretical mechanics) of APPLIED MATHEMATICS—Prof. L. R. Pounder, Department of Mathematics, University of Toronto, Toronto, Canada.

PHYSICAL CHEMIST (preferably Ph.D.) for research work on the kinetics of cellulose degradation—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester

RESEARCH ASSISTANT (with a degree in engineering or physics) AT THE NATIONAL COLLEGE FOR HEATING, VENTILATING, REFRIGERATION AND FAN ENGINEERING, to carry out research on heat transfer, refrigeration or aerodynamics, and possibly a small amount of laboratory demonstration—The Clerk to the Governors, Borough Polytechnic, Borough Road, London, S.E.1.

SCIENCE GRADUATE (trained in physics or physical chemistry, and preferably with experience in biological work) IN THE BLOOD PRODUCTS LABORATORY—The Secretary, Lister Institute, Elstree, Herts.

SCIENTIFIC OFFICERS (with first- or second-class honours degree or equivalent qualifications, in civil engineering or science, with geology or physics as principal subject), at the Royal Air Force Station, Cardington, for duties which include investigations into runway, building and road sites, and experimental work in soils engineering laboratory—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting G.240/53

SENIOR RESEARCH ASSISTANT (male) (with either a good honours degree in a biological science, or a degree in agriculture with post-graduate training in poultry husbandry, and with previous research experience), for programme of research on poultry husbandry, and an ASSISTANT (male), for poultry experimental work, with particular reference to table poultry production and marketing—The Bursar, Harper Adams Agricultural College, Newport, Shropshire.

REPORTS and other PUBLICATIONS

(*not included in the monthly Books Supplement*)

Great Britain and Ireland

Experimental and Research Station, Cheshunt, Herts. Annual Report (Thirty-Eighth Year), 1952. Pp. 88+2 plates. (Cheshunt: Nursery and Market Garden Industries' Development Society, Limited, 1953.) [2010

Aero Research Technical Notes. Bulletin No. 129: The Connecting of Pipes and Tubes with "Araldite": a Description of the Mitchell System. Pp. 4. (Duxford, Cambridge: Aero Research, Ltd., 1953.) [2010

Transactions of The Royal Society of Edinburgh. Vol. 62—Part 2—(No. 13), 1951–53: An Investigation into the Design and Performance of Electric Fish-Screens and an Electric Fish-Counter. By N. O. Lethlean. Pp. 479–520+2 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1953.) 13*s.* 6*d.* [2010

International Association for the Exchange of Students for Technical Experience. Sixth Annual Report. Pp. 60. (London: International Association for the Exchange of Students for Technical Experience, 1953.) [2110

FUEL PROBLEMS IN BRITAIN

THE debate on the fuel and power industries in the House of Commons on October 26 was perhaps the first occasion on which the fuel industries of Britain have been discussed with objectivity, and without nationalization being raised as a matter for party political dispute. Most speakers made a real effort to look at the three corporations concerned objectively and from the point of view of national rather than sectional interests. There was naturally some complaint that the time was too short for adequate discussion of the annual reports and accounts concerned, but that could have been an advantage had it stirred those participating to discuss the larger question of a national policy and the interrelationships of the three corporations, rather than their operation as independent units. None the less, the trend of the debate warrants the hope that although we have still to define the proper relationships between Ministers as trustees for the public interest and the numerous public boards, parliamentary criticism and debate on the nationalized industries of Britain may in future be concentrated increasingly on the proper objectives of policy and the merits or demerits of the particular means used to implement policy.

It could not be claimed, of course, that the debate indicated that the idea of the public corporations as trustees concerned with the efficient running of their affairs in the public interest has yet been fully accepted; but the atmosphere of the debate warranted a certain amount of confidence that we are progressing towards a clearer understanding of the proper use of the technical expert in the public service. To the technologist and scientist, interesting features of the debate were the references of the Minister of Fuel and Power, Mr. Geoffrey Lloyd, to the success of the National Coal Board's efforts in overcoming the shortage of technical men, particularly mining engineers, which has limited capital developments; to the changes in organization, making the Area the vital unit of higher management—a change conforming to the findings of the Acton Society Trust in recent studies; and to the examination of the whole organization of the Board which Sir Hubert Houldsworth proposes to institute.

Mr. Lloyd expressed the belief that developments in nuclear power would before long provide a useful addition to the resources of power in Britain, and he stated that the British Productivity Council has agreed to sponsor the non-profit making company which is being formed to take up the work of fuel efficiency. With the co-operation of industrialists, the Ministry is making a systematic survey of the generation and usage of steam by industry, which has already shown that one-fifth of the industrial boilers at present in use are more than forty years old. Replacement of these boilers by modern equipment offers savings estimated at two million tons of coal a year. He also said that the Government has introduced many of the higher standards recommended by the Ridley Committee and that many of the more efficient grates are coming into production.

While Mr. Lloyd claimed that there has been real progress in fuel saving, in the improvement of efficiency and in co-operation between the nationalized fuel industries and private industry, there were some significant omissions in his speech. Some of the strongest criticisms contained in the Ridley Report were ignored. His reference to the Minister's Co-ordinating Committee suggested that it is thought the Minister already possesses ample co-ordinating powers to ensure a national fuel policy so far as the fuel industries are concerned. Neither in his speech nor throughout the debate, save in Mr. A. Palmer's disparaging remarks, was there any reference to the report on fuel conservation, based on a visit to the United States last year of a specialist team on the conservation of fuel, heat and energy, recently issued by the British Productivity Council. This was the stranger because Mr. A. Robens, following the Minister, and again Mr. J. E. Powell, quoted Sir Ben Lockspeiser's recent remark: "We are still the champion coal wasters of Europe. We lack neither the science nor the technology to save from 15 to 20 million tons of coal a year, and at no greater cost than the additional expense we have had to shoulder by importing coal since the end of the war".

The importance of avoiding waste of fuel, in fact, received full emphasis in the debate, not merely as regards the domestic and industrial consumer but also in such matters as the location of power stations, the load factor in the electrical industry, and the necessity for an appropriate policy as one element in a national fuel policy. Even where it was contended, as by Mr. Powell, that the price structure advocated by the Ridley Report is inappropriate, the principle of co-ordination of the fuel and power industries in the national interest was fully endorsed; though it was contended that efficiency is best ensured by reasonable technical competition between the industries at a lower level and the preservation of some freedom of choice for consumers. Not all the implications of co-ordination were explored or indicated in the debate, but there was a most encouraging disposition to take a national point of view and not a sectional line. Weaknesses in regard to research and administration were noted, and the improvement of some particular condition was urged, not so much from the point of view of the workers affected as from that of the general benefit to the nation.

This in itself promises well for the future, and the various constructive suggestions made during the debate received a cordial welcome by the Parliamentary Secretary to the Ministry of Fuel and Power. Moreover, to the extent to which the efficiency of the individual industries depends, not merely on what are commonly termed industrial relations, but also on the outlook and spirit as well as the capabilities of the individual workers at all levels, the whole tone of the debate should be helpful. The question of accountability to Parliament of the public corporations may as yet remain unsolved; scarcely any reference was made to the recommendation in this connexion of the last report of the Select Committee on the Nationalized Industries, although Mr. Nabarro expressed the hope that the Standing Con mittee suggested would soon be constituted. Neve theless, if Parliamentary scrutiny and discussion the work of the public corporations continues o lines as constructive and objective as those of th debate of October 26, and the Ministers responsib show themselves in practice as responsive as th Minister of Fuel and Power appeared to be, th problem of securing efficiency and public account ability should be largely solved. Further, the tempe and publicity of the debate should contribute also t remove misunderstandings and feelings of isolatio such as those to which Mr. Robson Brown and other rightly referred, and bring into all sections of th nationalized industries not merely a sense of th national interest, but also—and no less important— a sense of belonging to and being understood by th whole community.

That is not to say that all is well in the fuel an power industries of Britain, or that the Governmen has done all that is possible to formulate a nationa fuel policy, including an appropriate price structure or to achieve savings in fuel. The Productivit Report on the Conservation of Fuel, Heat an Energy may call for criticism in some points: it di not deserve to be virtually ignored. Admittedly, i was what has been called an 'angry' report; an the specialists have perhaps overlooked the importance of the human factor, both on the production an on the consumer side, which Mr. Aubrey Jones rightl stressed in the House of Commons debate. Personalit is more important than organization, to the exten that without it even the soundest policy or the mos perfect organization will not function. Effectiv leadership turns above all on personalities, and fo that reason alone the content of overall fuel polic and the means necessary for implementing it mus take more account of the human element than th specialist team appears to have done. Public apath and inertia may be deplorable and irritating, bu they represent a factor of which due account must be taken both in the formulation of policy and the choice of means of executing it.

The virtual ignoring of this report in the House o Commons and by the Government is not to be excused on the grounds of over-emphasis on the part of the experts concerned. It can only be condoned when the Government itself produces a fuel efficiency programme, comparable in extent and urgency with that urged by the team, and shows that it is tackling the difficulties in the way of framing a national fuel policy much more vigorously than was evident in either Mr. Lloyd's opening speech or Mr. L. W. Johnson-Hicks's reply on the debate. The debate did not supply evidence that fuel saving has yet the place it should have in the programme of the Government or that, even with the new Fuel Efficiency Organization, enough will be done to further public education in this matter.

It is true that there is not a great deal that is new about the conclusions and recommendations of the Productivity Report on fuel. None the less, they give a useful, if somewhat authoritarian, statement of measures required and of the priorities, though the ecommendation for the establishment of a commission to formulate a national fuel policy or for the o-ordination of the nationalized coal, gas and lectricity industries under a Fuel and Power Board ignores the co-ordinating powers which the Minister lready possesses—even if he has made scant use of hem. More could undoubtedly be done to provide ffective financial incentives to encourage industry to install efficient fuel-burning plant and equipment, nd a large measure of responsibility lies on the Government also for the encouragement of co-operation in joint services for the supply of steam and ower instead of by generation of steam in individual works and factories, seeing that financial and taxation policies do so much to discourage investment of this kind.

The Productivity team may well have erred in under-estimating the other factors in the situation when urging the installation of new and efficient plant and appliances either in industry or for domestic use, and it appears to go too far towards dictatorship. The relation between the cost of labour and the cost of equipment to replace it has to be considered, as well as the cost of the energy generated and used by he equipment, with which the team is inclined to be preoccupied, in discussing or comparing industrial fuel practice in the United States and here. This discussion, probably the most useful feature of the report, is rather obscured by the more contentious recommendations which precede it. The team believes that a higher level of efficiency in the utilization of fuel and power prevails in the United States than in Britain, and on the evidence it presents this conclusion may be right. Further, it regards the development and rapid expansion of American industry as directly reflecting a vigorous exploitation of ample supplies of fuel and power, energy consumption per head of population being by far the highest in the world. The stores of energy in the United States are so vast and relatively inexhaustible that there are no inhibitions as to its use, nor is there great anxiety as to future supplies.

In this context, it must be remembered that in the United States 54 per cent of the energy used comes from sources such as oil, natural gas and hydroelectricity, 'fuels' inherently easier to handle and less likely to be wasted than coal, whereas in Britain coal supplies 90 per cent of all energy used. Again, while American industry is disposed to replace all its equipment sooner, this is not due simply to a more favourable financial policy. The ratio between the cost of labour and the cost of equipment to replace it differs in the two countries, and how far British industry should go in this direction depends eventually not simply on thermal efficiency but on the return to be obtained on investment. Government policy can increase or decrease that return but only within limits, and Britain's overwhelming dependence on coal thus sets limits to what can be accomplished by educational campaigns or a fuel-efficiency organization.

As has already been urged, the importance of financial incentives, in the way of tax reliefs rather than loans, should have received greater emphasis as the only effective means of furthering fuel efficiency in those branches of industry in which the cost of fuel is a secondary factor. Apart, however, from the prevailing apathy to fuel economy, sociological factors are so important that the Productivity team is not to be rebuked for straying into such fields instead of confining itself to purely technical questions. Even in the happier atmosphere of the House of Commons debate, which did something to meet the team's hope that the fuel industries might be considered from a national point of view and not from that of political parties, the report and its reception raise afresh the issue of securing effective action on technical advice. Moreover, as Sir Harold Hartley remarked in his recent Melchett Lecture to the Institute of Fuel, particularly in considering domestic fuel problems, psychological as well as economic and technical factors are important. Clearly, as Sir Harold indicates, the fuel industries could do more than they have yet done, even in the past quarter of a century, to create the conditions favourable for progress in the use of more efficient appliances. That could also be encouraged further by the Government, and financial policy or pricing policy could be a powerful determinant, too, in the choice of particular types of fuel, as well as of appliances. Except, however, in the broadest terms, it is difficult to see that the Government could go far in formulating a long-term policy, other than the removal of anachronisms and such competition between the fuel industries as is detrimental to the national interest. What matters above all is to see that attention to efficiency at a particular time does not impede the receptiveness to new ideas. As Sir Harold remarked further, it would be unwise to take any decision in regard to domestic or industrial heating which would determine for years to come the direction in which development must take place. Real progress, the most effective utilization of all Britain's limited fuel resources, will only be ensured if technologists are afforded full scope. If, for example, means are found of applying the principles of the heat pump to equipment which can be used in houses, the balance of demand would be markedly affected, and electricity and gas might then begin to acquire a large part of the load.

There were other ideas ventilated in the House of Commons debate, and it is for this reason that the slender expenditure on research of the British Electricity Authority is disturbing. Its fifth annual report recorded an expenditure of only £138,835 on research in 1952–53 compared with £140,327 in the previous year; and this small figure has to be set against a fall in the load factor of generating equipment to 44·9 per cent compared with 47·4 per cent in 1951–52. Possibilities of improving this and of saving coal consumption, for example, by the use of gas turbines, are indicated and discussed in the report itself. For the same reason, the decision of the Gas Council to spend a million pounds during the next five years on surveys of parts of Yorkshire, Lincolnshire and Scotland for sources of natural gas is to be welcomed; the surveys are being carried out for the

Council by the d'Arcy Exploration Company, a subsidiary of the Anglo-Iranian Oil Co., Ltd.

Besides this, the Gas Council proposes to investigate the further improvement of methods of production, and Sir Harold Smith has pointed out that success in these ventures would transform the whole economics of the gas industry. The rise in the price of coal since vesting day has added £25 millions to the Council's annual coal bill: the last rise of 10 per cent in pithead prices, which came into force on March 2, 1953, is estimated as costing the gas industry more than £8·5 millions in a year. Moreover, coal for gas-making is getting scarcer as well as dearer. The country's reserves of high-grade coal necessary for gas manufacture are running out, and the Gas Council and the Coal Board are both anxious to find effective substitutes.

Nevertheless, though there is plenty of room for research and need for a more vigorous policy than is evident in the latest report from the British Electricity Board, the two chief requirements in regard to the utilization of fuel in Britain are, first, Government intervention to secure concerted action and policy on the part of the fuel industries rather than the independent and sometimes conflicting policies and lines of action pursued by the coal, gas and electricity corporations—actions of which the Productivity team rightly complains; and second, the effective utilization of existing knowledge. Remedies for most current abuses in the use of fuel are well enough known. What is needed is a vigorous campaign, with possibly some further Government encouragement in the way of financial incentives or taxation relief, to secure action on that knowledge. No fresh organization or commission such as the Productivity team suggests will have much effect if the Government, or the Minister, is reluctant to use the powers and knowledge already available. The avoidance of waste of existing fuel supplies, the increase of efficiency of production and the development wherever possible of fresh sources of fuel and power, are matters of urgency for the immediate as well as for the more distant future of Britain.

PLANTS OF THE BIBLE

Plants of the Bible
By Dr. Harold N. Moldenke and Alma L. Moldenke. (A New Series of Plant Science Books, Vol. 28.) Pp. xx+328+36 plates. (Waltham, Mass.: Chronica Botanica Co.; London: William Dawson and Sons, Ltd., 1952.) 7.50 dollars.

POLITICAL upheaval and racial strife apart, much has happened in Palestine during the twentieth century. Each decade has revealed extraordinary archæological treasures: the chance findings of the ancient Scrolls of the Law in a cave near the Dead Sea; the systematic researches resulting in the discovery of the ivories in Ahab's summer palace at Samaria; and the recent find of the seven thousand year old clay portrait-busts on human skulls at Jericho. With the advent of hydroelectric power and irrigation schemes, enormous strides have been made in agriculture, horticulture and botany, and this has brough a renewed interest in the plants of the Bible, a interest so strong that at the Hebrew University o Jerusalem there is now a professor of biblical botany Dr. Ha-Reubeni, who already has thrown muc valuable light on this fascinating subject and n doubt will continue to do so.

On no other aspect of botany has so much bee spoken and written, by so many people, in so un scientific a fashion. In my opinion, Dr. and Mrs Moldenke's book is the most authoritative and comprehensive statement on the plants of the Bible tha has been published. Theirs is a completely new scientific survey of the subject. As well as makin researches into the works of classical and historica translators, they have consulted all the contemporar translations and commentaries of the Protestant Catholic and Jewish Bibles, and the result is a wel correlated volume equally accessible to the reader of these three great faiths, as well as a most extensiv bibliography of more than six hundred items i which it is surprising to find no reference to Hasting' "Dictionary of the Bible" nor to Sir Georg Adam Smith's "Historical Geography of the Hol Land".

Including algæ, fungi and bacteria, some tw hundred and fifty plants are alphabetically listed and described under their botanical name. Th reason for this sequence is not clear, and surely i would have been more convenient to have had th plants arranged alphabetically under their Bibl names. This is a book not only for botanists but als for Bible scholars and others as well; and not al botanists by any means (let alone non-botanists) wil know that for an account, for example, of th "juniper" of the Scriptures they must turn to th chapter on *Retama raetam* (Forsk.) Webb. and Berth., or for an account of the "hyssop" to th chapter on *Origanum maru* L. With the present arrangement, one spends a lot of unnecessary time with the index.

Always there have been differences of opinion about these Bible plants, and of some of them n doubt there will always be differences of opinion. Dr. and Mrs. Moldenke, in their many discussions, present their case fairly and without prejudice t other writers. One wishes, however, in many instances that their own arguments and the arguments of others could have been presented in greater detail. Why, for example, do the authors regard *Narcissus tazetta* L. as the "rose" of Isaiah 35:1, and why do all modern commentators refuse to accept Royle's scholarly arguments that the "hyssop" was the common caper *Capparis sicula* Daham? In such matters as these this book lacks the interest to the general reader which Canon Tristram so superbly gave.

There are twenty pages of supplementary notes with, and most important, a promise of further supplements to appear from time to time in "Chronica Botanica". These notes bring up to date completely our knowledge of Bible plants, and some of them are of very great interest indeed. For example, the discovery of *Lilium candidum* L. growing wild and apparently indigenous on the mountains of Upper Galilee near the frontier between Palestine and Lebanon suggests that this plant may have had a fairly wide distribution in the time of Christ and possibly may have been the "lilies of the field" for which *Anthemis palestina* Reut. was postulated in 1925 by Dr. Ha-Reubeni.

There are many illustrations ; some are of mythogical figures and some are of reproductions and original drawings of the plants discussed in the text. ll these are good. The woodcuts, however, at the end of certain chapters are insufficient for purposes of identification and serve no useful purpose. Moreover, it is a pity that no modern photograph of Israel and Jordan has found a place in this modern text-book on Bible plants. Those plates which attempt to portray the scenery of the Holy Land are wood engravings from C. W. Wilson's "Picturesque Palestine", published in 1883. H. R. Fletcher

PENCK'S "MORPHOLOGICAL ANALYSIS"

Morphological Analysis of Land Forms

A Contribution to Physical Geology. By Prof. Dr. Walther Penck. Translated by Dr. Hella Czech and Katharine Cumming Boswell. Pp. xiv+429+12 plates. (London: Macmillan and Co., Ltd., 1953.) 2s. net.

WALTHER PENCK'S "Die Morphologische Analyse" was published in 1923, after his death at the age of thirty-five, by his father, Albrecht Penck. The original German work was written in a manner difficult to read for anyone except an expert linguist and for that reason may not have received as much notice as it should have done at that ime.

The present translation by Dr. Hella Czech and the late Miss Katharine Boswell emphasizes the difficulty. They have kept the translation as literal as possible; but even so, it must be admitted that the present book is far from easy to read. Yet if they had not done this, they would have had to give an interpretation rather than a true translation of his book. Whether or not the volume will succeed in making clear Penck's views is debatable. Miss Boswell, whose sad and premature death took place before the appearance of the volume, has added some valuable summaries of each chapter; but despite the care she has given to them, they do not entirely succeed in making clear the precise implications of the full accounts.

Penck was particularly concerned with slopes—their shapes, declivity, development, and so on. He has been responsible for provoking a great deal of work on this problem, which is one of fundamental importance. He correlated the form of the slopes with earth-movement, and assumed that the initiating condition for the development of land forms was a long-continued and very slow upheaval, which might affect either a newly developed basin of sedimentation or an old peneplain, or some variant of these forms. Unlike W. M. Davis, he did not consider development under the heads of youth, maturity and old age, but in terms of an analysis of the developing slopes. In brief, waxing or accelerated (*aufsteigende*) development implies convex slopes and relatively quick upheaval, waning or declining (*absteigende*) development leads to concave slopes because the movement by upheaval is dying out, and uniform (*gleichförmige*) development implies a balance between slope evolution and diastrophic movement. Penck, in fact, thought of morphological analysis as the means of deducing the nature of crustal movements from the landscape features themselves as well as from the (exogenetic) processes working on them. He insists that the problem is that of crustal movement, and that it falls in the realm of geology.

To develop his views on slope evolution Penck analyses in some detail the processes of weathering, the ways in which rock debris is formed, the laying bare of surfaces, and the whole question of the removal of waste. This is termed 'denudation' (*Abtragung*), a word which he does not apply to stream 'erosion'. 'Corrasion' is defined as "the freeing of loosened rock-fragments from the place of origin". The reader must therefore appreciate Penck's terminology. Penck's hypothesis implies, too, that the angle of slope retreat will be maintained as long as the factors initiating it are not altered—in short, there is parallel retreat of slopes. Even where down-cutting ceases, parallel retreat of the upper slopes is maintained; but new processes begin to work on the foot of such slopes, since conditions now mean that, apart from lateral corrasion, the stream cannot remove the waste accumulating from above. "The under surface of the talus is always a slope with a gradient less than that of the rockface above. This is the basal slope (*Haldenhang*). . . . Where the basal slope meets the rock wall. . . . is the top of the basal slope (*Haldenscheitel*). The accumulation of talus does not simply bury the rock wall and thereby remove it from further decay; but together with the inclined basal slope, it grows upward at the expense of the wall."

It is helpful that this translation has appeared because for the first time it may introduce Penck's treatise to a number of readers who would otherwise have had to learn about it indirectly. It is doubtful if it will make his conceptions completely clear. It should be remembered that he intended to publish a larger work in which he would have developed his thesis more fully. Physiographers have found Penck's ideas provocative, although many now would challenge his correlations between diastrophism and slope form. But one must ask: Is this translation not too delayed relative to the publication of his original book? It may seem ungracious, but it is worth suggesting that a lengthy essay written by someone familiar with both Penck's work and with the field evidence of the subject-matter is really what is required. J. A. Steers

LABORATORY EXPERIMENTS WITH RADIOACTIVE MATERIALS

Experimental Nucleonics

By Prof. Ernst Bleuler and George J. Goldsmith. Pp. xv+398. (London: Sir Isaac Pitman and Sons, Ltd., 1953.) 30s. net.

THIS book is concerned with laboratory experiments originating from a course at Purdue University in the United States. The experiments relate to radioactive materials and the techniques used for measuring and separating them, and they are intended as part of the fundamental training of "people who anticipate performing tracer research as well as students of nuclear physics". The text is divided into three parts allotted respectively to techniques of counting and handling, with general applications; experiments in radiochemistry; and experiments dedicated to students of nuclear physics itself. Biologists, engineers and civil-defence personnel are among those who will also find the first section relevant.

Interest in this kind of book obviously appears mainly among those concerned with education and training, though industrial and government establishments may be included in this category as well as schools, universities and colleges. Although teachers will enjoy comparing the suggested courses with their own, the book should be regarded as a reference work, for there are detailed and careful sections on equipment, experimental procedure, and "evaluation and report", which make continuous reading heavy going. Also, in Britain, rigid adherence to these sections in a laboratory course is not very probable, as much of the apparatus and some of the materials used at Purdue are different from those generally at hand here. (Some of the references are also less accessible here. For example, United States Department of Commerce publications relating to health hazards and precautions may be less attractive than the "Introductory Manual on the Control of Health Hazards from Radio-active Materials", available from the Isotope Division at Harwell.) Teachers may also feel that these detailed experimental instructions leave too little to the student's imagination. On the other hand, the sections on the theoretical background which accompany each experiment lose little of their value in crossing the Atlantic. Apart from the variations in symbols and notation, which, as the authors say, are an inevitable feature of nuclear study at present, these sections would apply to almost all introductory laboratory courses in the techniques relating to radioactivity.

The experiments described in Part 1 would be generally accepted as suitable material for this kind of course. They include Geiger counter and ionization chamber techniques, but scintillation counting is relegated to the nuclear physics section, and the proportional counter has only scanty treatment. Some amplification of the neutron mean-life experiment would increase its value to engineers studying nuclear energy; for example, indium foil activation enables the neutron distribution to be examined.

The remaining parts of the book describe experiments which are best regarded as further training in the techniques dealt with in Part 1. The chemical and physical theory involved is not in itself up to honours degree standard, while there is no extensive investigation of possible applications of the techniques of radioactivity in research in either field. The references at the end of each chapter, which include publications up to 1951, do enable more elaborate or comprehensive ideas to be followed up, however.

R. L. Fortescue

APPLICATIONS OF ELECTRICITY IN HORTICULTURE

Electricity in the Garden

By Geoffrey Gerard. Pp. x+125+16 plates. (London: W. H. and L. Collingridge, Ltd.; New York: Transatlantic Arts, Inc., 1953.) 15s. net.

THE Briton is an inveterate gardener. In few countries can there be a greater proportion of keen amateurs, assiduously cultivating their home plots, often under far-from-promising climatic and topographical conditions. It is good that this should be so. We needed all the home-grown food that coul be produced during the War and, if shortages a now less acute, there is still profit—and muc pleasure—to be gained from gardening as a hobb As electricity has become a great benefactor in th home, so it can be also in the garden. Electricall operated appliances for the garden are not reall new but, in spite of their continued developme during the past two or three decades, and the publicity which has been given to them from time t time in gardening journals and at horticultur shows, they are not as widely appreciated as the should be. Mr. Geoffrey Gerard's book is thu opportune. It should be very useful to the knowledgeable gardener in providing him with informatio on the best methods of using electrical equipmen which he may already possess, or may acquire, a well as giving, for the benefit of the uninitiated, comprehensive account of the possibilities. Bu the book is not confined to matters of interest onl to the amateur; electrical methods for soil warmin in frames and glasshouses, space heating and artificia illumination certainly concern the professional grower and many of the illustrations are taken from commercial practice.

There are, of course, several important factors varying widely in natural conditions, which affec the growth of plants—light, air temperature an humidity, soil temperature and moisture content and the carbon dioxide content of the air a well as the chemical, bacteriological and mechanical conditions in the soil or other growing medium. In spite of research extending over many years, we are still far from knowing exactly wha relative values of these quantities are required t bring about optimum growth at different stages o the development of plants; but plant physiologists such, for example, as Dr. F. W. Went, of Californi Institute of Technology, seem to be approaching the point where they can give a 'recipe' for growing some of the more important horticultural crops. If they succeed in doing so there is little doubt that electrical methods of controlling these factors precisely can be found. The problem for the commercial grower will then be to decide how far he can afford to go in applying these methods in his practical operations. Mr. Gerard's book does not attempt to instruct the grower in such economic matters but, at least, the author has taken pains to present the results of up-to-date research and development. He has drawn freely on the Electrical Research Association's reports upon its electro-horticultural researches at the Shinfield Field Station, and has given full references to these and other publications which can provide the interested reader with more detailed information.

It is good to note also the care which has been taken to point out the dangers of bad workmanship in installing the necessary electrical equipment. The chapters giving some instruction on the elements of electrical engineering and on maintenance of the installation are appropriate and are clearly written, and there is also an appendix giving the Draft British Standard Code of Practice for Farm and Horticultural Electrical Installations.

The book is well produced, and both the photographic and line-drawing illustrations are particularly good. If one feels that its price is rather high, that may be due to the difficulty in growing accustomed to the present-day costs of producing a book of this kind.

E. W. Golding

BRITISH RAILWAYS WIND TUNNEL

By D. W. PEACOCK

WIND tunnels, indispensable in aeronautical research, are increasingly being recognized as qually successful for aerodynamic problems in other ields of engineering, and it was with these conderations in mind that in 1934 the directors of the ormer London, Midland and Scottish Railway authorized the installation of a wind tunnel t the L.M.S. Research Department at Derby. The most important aerodynamic problem at that time was the streamlining of locomotives and trains, on which useful work was done, while it was later found that the wind tunnel was increasingly employed on large variety of railway aerodynamic problems[1]. The tunnel was of the straight-through type, with s design based on similar tunnels in use at the National Physical Laboratory at the time. It had working section 4 ft. 6 in. wide by 3 ft. 6 in. high, 4 ft. 3 in. long, and was capable of a maximum speed of 60 miles per hour. The tunnel gave satisactory service until it was necessary in 1952 to move t from its site, and the opportunity was then taken to build a new 100 m.p.h. wind tunnel, incorporating the working section of the old tunnel and its electrical driving gear, and using the same test apparatus. Incidentally, it is believed that the old tunnel and its successor are the only railway-owned wind tunnels in the world in regular use.

The new tunnel has recently been brought into operation and was opened on October 19 by Dr. F. C. Johansen, of the Avery Research Administration, who, when engineering research officer for the L.M.S. Research Department, pioneered and installed the first wind tunnel. The new tunnel is housed in a converted building near the main British Railways Research Department building at Derby, and the general arrangement is shown in Fig. 1. The tunnel construction is mainly in wood, with ply-wood walls or lining, and the fan section is steel, the interior surfaces being painted and varnished to give a good smooth continuous finish. The tunnel is of the closed-working section return-circuit type which gives good airflow conditions and

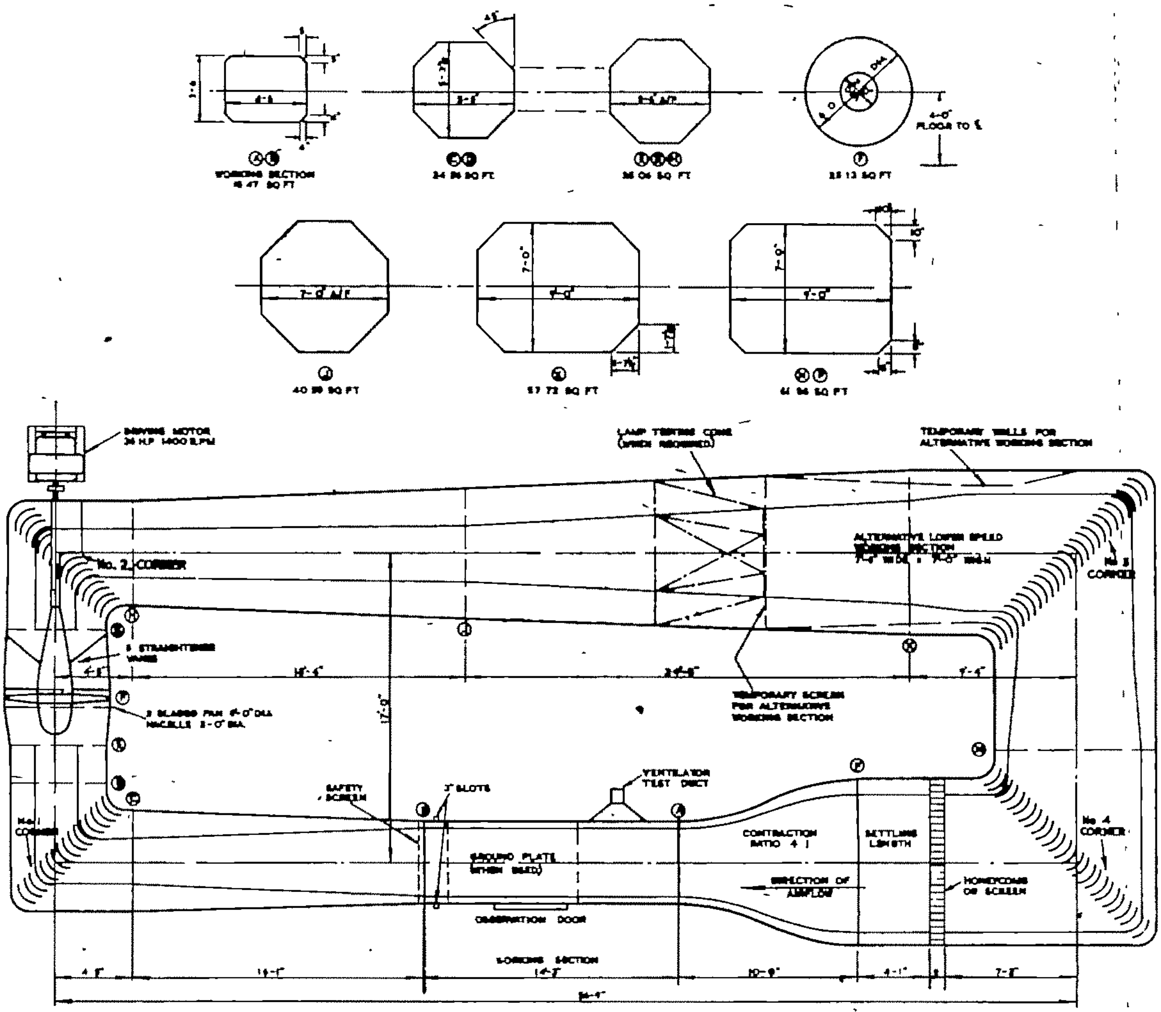

Fig. 1. Line diagram of the Derby return-circuit wind tunnel : scale ¼ in. to 1 ft. Corners 1 and 2, 16 turning-vanes ; corners 3 and 4, 26 turning-vanes

economical use of power. The working section from the old tunnel has been renovated and adapted, and slots are cut in the walls at the downstream end to establish the static pressure as atmospheric. A 4-in. mesh safety screen of streamlined wires is fixed here to catch any part of a model which may accidentally break loose.

From the working section the air passes along an expansion to the first corner, which is fitted with thin turning-vanes made of rolled aluminium sheet, the same turning-vane section and pitching being used at all the four corners. The general layout of the tunnel led to the fan being most conveniently situated between the first and second corners. It is two-bladed, 6 ft. maximum diameter with a 2 ft. diameter boss and nacelle, the blades being made of laminated mahogany, covered with a plastic skin impervious to moisture. The fan is directly coupled, by a long shaft which passes through the tail of the nacelle and through a fairing at the second corner, to a 36 h.p. 1,400 r.p.m. direct-current motor situated outside the tunnel, the electrical equipment being of the Ward–Leonard type, which provides accurate and economical speed control from crawl to full speed. The nacelle is supported immediately downstream of the fan by five symmetrical aerofoil straightener vanes which remove any rotation in the airstream, and the fan section is designed with approximately constant net area. The air then passes round the second corner and along the return duct, where the section changes gradually to rectangular 9 ft. wide by 7 ft. high (with corner chamfers). Throughout the circuit the equivalent cone angles of the expansions are no more than 4·8°, the maximum expansion in any plane not exceeding 7·1° (except for a short length across the chamfers at the third corner).

At the third and fourth corners the largest cross-section has been reached, and the air then passes through a honeycomb 9 in. long with 2-in. square cells, made of brass sheet with soldered joints, which breaks up eddies and smooths out irregularities in the airstream. The honeycomb can be replaced by a phosphor-bronze screen of 14-mesh 24 S.W.G. wire, to give increased quality of airflow at the expense of some reduction in maximum tunnel speed. The honeycomb is followed by a settling length 4 ft. long, and a 4 : 1 contraction 10 ft. long, the profile of which is designed to give uniform velocity distribution at the start of the working section.

The aerodynamic design of the tunnel was undertaken by British Railways, after consultation with the National Physical Laboratory and the College of Aeronautics, Cranfield. The fan design and gene construction of the tunnel were carried out by t Airscrew Company and Jicwood, Ltd., Weybridg the tunnel was built in sections at their works a assembled on site at Derby.

Standard wind-tunnel instruments are employ for the determination of air forces and speeds. Tv general-purpose single-component balances are ava able, and wire suspensions are employed to conne the models to the balances. This arrangemer though having a high suspension drag, enables simp balances to be used, and has given good result Pressure plotting can be carried out by the use of multitube manometer. Equipment is provided f flow visualization by the use of smoke generated b dropping paraffin or lubricating oil on an electrical heated hot-plate. Models of locomotives and rollin stock are tested over a thin flat plate representir the ground, and for the sake of simplicity a fix ground-plate has been employed.

A full-sized railway signal can be put into th working section for testing oil-burning signal lamp and a test duct is installed for railway coach an roof ventilators. In the return section provision h been made for the temporary fitting of a plywoo contracting cone which enables a 60 m.p.h. jet air of about 4 ft. diameter to be produced for th testing of shunters' hand lamps, where both th effects of wind and manipulation require to b obtained simultaneously, or for other tests whe the investigator requires to be in the airstrean Before the third corner, there is room for an altern tive lower-speed working-section in which can b placed a larger site model in the study of such problem as dispersal of smoke from tall chimneys, and it hoped that the airflow here can be made reasonabl uniform by the temporary fixing of one c more screens, with a maximum airspeed of abou 22 m.p.h.

The tunnel has so far been given a preliminar calibration, which has shown that the velocity dis tribution and steadiness in the working-section ar good, and that the speed attained with a clear tunne is 112 m.p.h. with honeycomb, and 98 m.p.h. wit screen, both being taken with an output from the fa motor of 36 h.p. The corresponding power factors defined as ratio of horse-power to fan to kineti energy at working-section, are 0·24 and 0·36, value which compare well with similar wind tunnels.

The immediate programme proposed for the nev tunnel includes work on air resistance of wagons heat dissipation from axle-boxes, smoke dispersa from engine sheds, and the design of roof ventilators

---

METEOROLOGICAL CONFERENCE AT TORONTO

METEOROLOGISTS are notably and necessarily internationally minded, and the American Meteorological Society, the Royal Meteorological Society and the Canadian Branch of the latter have recently realized a new expression of this spirit by holding a successful—first—joint meeting. It took place in the University buildings at Toronto during September 9–15, the Canadian Branch of the Royal Meteorological Society acting as the very generous hosts. Prof. H. R. Byers (Chicago), president of the American society, sowed the seeds of the meeting, and its realization was made possible by a generous grant from the Munitalp Foundation of America. Mor than 250 meteorologists attended, of whom about twenty formed the British delegation from overseas A necessarily selective account of the nine symposia which were held is given below.

The first session was on ozone and the high atmosphere, under the chairmanship of Sir Charle Normand, president of the Royal Meteorologica Society. It was largely descriptive in content, fo knowledge of the stratosphere and higher layers i not yet sufficiently precise and comprehensive tc evoke a well-conceived dynamical theory which, it i w at least evident, is required to give meaning to e observed structure; radiation thermodynamics certainly not enough, although there is much work r it to do. An admirable survey of ozone behaviour the chairman suggested, however, that dynamical eteorology might well soon profit by much of the idence now accumulated on the spatial and tem-ral distribution of ozone. Recent additional udies of its vertical distribution were presented by . S. Johnson (U.S.), from rocket solar spectra, and y R. M. Goody (Great Britain), from ultra-violet nd infra-red solar spectra observed at the ground. emperatures and winds at high levels as currently easured by means of sounding balloons, from the ropagation of sound, by observations on noctilucent louds and by means of ionospheric radio reflexions ere described; but a coherent picture of the otions, and of the thermal gradients in the meridional nd vertical directions, did not emerge.

The second symposium, on radiation problems, nder the chairmanship of Dr. G. D. Robinson (Great ritain), was appropriately divided into three ections, one on the methods of computation of the lux of atmospheric radiation, a second on laboratory nvestigations of infra-red spectra, and a third on he application of radiation studies in physical limatology. The material of some of the speakers as too detailed for immediate apprehension by all ut a very few specialists, and will wait on more uitable occasions for appraisal. It is, however, vident that the complexity of infra-red absorption nd emission in the atmosphere is slowly being astered, to the end of computing reliable values f flux and, more particularly, of flux divergence position and strength of radiation heat sinks) in model atmospheres. The validity of simple, approximate treatments for day-to-day application might then be tested. An interesting 'savoury' to the discussion was provided by A. W. Brewer's report of the first actual measurements of atmospheric radiation above the tropopause by Houghton at Oxford.

Canada now has an extensive network of Arctic *radio-sonde* stations, and it was appropriate, therefore, that a session should have been devoted to Arctic meteorology, with Andrew Thomson, controller of the Canadian Meteorological Service, in the chair. H. U. Sverdrup (Norway) showed how certain problems in atmospheric radiation and heat transfer are peculiarly amenable to investigation in high latitudes owing to the absence of solar radiation and the presence of snow surfaces with extreme thermal properties. Results obtained on the recent Norwegian–British–Swedish Antarctic Expedition were also presented. F. W. Rae (Canada) spoke on the setting up and maintenance of an Arctic *radio-sonde* station, and H. P. Wilson (Canada) described an investigation of cyclone behaviour within the Arctic Circle.

The next three sessions, on the general circulation of the atmosphere (chairman, Prof. P. A. Sheppard, Great Britain), on modern cyclone theory (chairman, Prof. S. Petterssen, U.S.) and on high-level forecasting (chairman, General W. O. Senter, U.S.) may conveniently be treated together as atmospheric dynamics and thermodynamics. The mean wind systems of the globe up to a height of about 20 km. are now becoming tolerably well established, and the problem is to account for their maintenance against dissipative processes and in the presence of large-scale turbulence provided by the migratory long waves, cyclones and anticyclones, and of other, smaller-scale motions, the whole to conform with the distribution of energy sources and sinks. Papers were presented describing the momentum transfer by turbulence from low to high latitudes and in the vertical, and there was some speculation on the role of quasi-steady large-scale overturning of the atmosphere in meridional planes (mean meridional circulations) in the general circulation. These necessarily small mean meridional motions are difficult to establish where zonal motions many times larger are present, as is mostly the case. But they can be most important in the creation of relative (air to earth) zonal or angular momentum, because of the earth's rotation.

Cyclones not only play a fundamental part in the transfer processes of the general circulation but are also, of course, of intrinsic interest and great practical importance. While it has been shown that, for example, a westerly current which increases with height may be dynamically unstable and so give rise to disturbances of the scale, form and growth-rate and perhaps with the transfer properties which we observe, other forms of shearing instability are regarded as possible, and J. Bjerknes (U.S.) spoke on these. The nature of the instability in individual cases is, however, scarcely identifiable, and a new technique of investigation is now being exploited. This is to carry out numerical integrations of the hydrodynamical equations of motion, using electronic digital computers, and working from initial observed states of the atmosphere. The equations are first simplified to such a form as is thought valid for developments of the scale concerned. J. G. Charney (U.S.) described a particularly strong case of cyclonic development computed in this way, and gratifying success over 24-hr. intervals was achieved. The particular simplifications of the equations correspond, of course, to assumed model behaviours of the atmosphere, and already a sequence of models of increasing complexity has been investigated in a search for that model which is sufficiently realistic and also amenable to machine computation. The application of the technique to day-to-day forecasting is not the least of its potential rewards.

The jet stream of the upper troposphere remains obstinately outside current dynamical theory, but much work of a descriptive kind on the behaviour of the jet and on smaller-scale motions associated with it, some made visible by aircraft condensation trails, is in progress and was reported upon.

Sessions on climatic change (chairman, Prof. G. Manley, Great Britain) and on micrometeorology (chairman, Dr. C. W. Thornthwaite, U.S.), that is, on the extreme ends of the atmospheric turbulence spectrum, produced a crop of papers indicative of the current activity in these fields. It was particularly appropriate to hear speakers discussing the phase differences of climatic change on the two sides of the Atlantic, and as intriguing as ever to note the diverse forms of evidence which are brought to bear, with more or less certainty, on this problem. Fact-finding is still the need, though the facts for times before the instrumental records begin must necessarily be transformed by imagination controlled by critical power. Theorizing is not at present of great power; for here, as much perhaps as elsewhere in meteorology, cause and effect seem to be almost inextricably mingled.

The micrometeorologists ranged from the very practical problems of the micro-climate of the potato crop and of atmospheric pollution to the sophisticated investigation of isotropic and anisotropic turbulence near the earth's surface. The difficulty in separating turbulence from mean motion in the latter work was again made manifest. Dr. H. Lettau (U.S.) concluded this symposium with a colour film of a large joint project undertaken a month before on the great plain of Nebraska, where a dozen or so teams compared their methods of measurement of mean profiles and the vertical transfer of momentum and heat.

The final symposium, on cloud physics and induced precipitation, under Prof. H. G. Houghton (U.S.), began in the laboratory and ended in large-scale weather systems. It is now well known that the laws of supercooling of water droplets are intimately concerned in the colloidal stability of clouds, and Dr. C. L. Hosler (U.S.) showed how supercooling increases with decrease in drop size and increases or decreases according to the nature and amount of the hygroscopic material forming the nucleus of the drop. Radar studies of precipitating cumulonimbus clouds by the Chicago school have shown how the initial radar echo, that is, the region containing precipitation particles as opposed to cloud droplets, appears wholly below the 0° C. level and later grows both upwards and downwards. This was interpreted as evidence that the ice-phase is not essential in inland areas such as Illinois for the initiation of shower precipitation, but no mechanism of initiation was suggested. If the interpretation is sound, the stimulation of a cloud to produce precipitation using ice-forming agents can scarcely be adequate. K. C Pettit (Canada) described cloud characteristics a inferred from aircraft-icing investigations, and th Massachusetts Institute of Technology school pre sented the results of a very detailed investigation o five depressions by aircraft, ground radar, etc. The relate precipitation patterns to cloud developmen cloud-particle form and concentration, fronta structure and upper-level flow fields—an investigation, it appears, from which much may ultimately b inferred on the physics, including the dynamics, o the production of cloud and precipitation in th depressions which constitute so much of temperat latitude weather.

The Conference was stimulated by a number o social functions: a conversazione by the Canadia Branch of the Royal Meteorological Society on th first evening, a reception by the Lieutenant Governo of Ontario, an excursion to Niagara Falls, and cocktail party (by the Friez Instrument Co.) an dinner on the last evening. The dinner was notabl for speeches from the Minister of Transport fo Canada and from Mrs. C. Beech, of the Munitalp Foundation, and for the announcement of th election by the American Meteorological Society o the first six honorary members on its roll: of these five were British—Sir David Brunt, Sir Nelso Johnson, Sir Charles Normand, Mr. J. Patterso (Canada) and Sir George Simpson; the sixth wa the distinguished Norwegian geophysicist, Prof H. U. Sverdrup.

P. A. SHEPPARD

COSMIC-RAY PRODUCTION OF HELIUM IN METEORITES AND THEIR AGES

By DR. J. C. DALTON, PROF. F. A. PANETH, F.R.S., DR. P. REASBECK, DR. S. J. THOMSON
Londonderry Laboratory for Radiochemistry, University of Durham
and DR. K. I. MAYNE
Clarendon Laboratory, Oxford

IT has recently been proved that a major part of the helium found in iron meteorites is due to the influence of cosmic rays[1]. This interaction should produce helium-3, helium-4 and tritium (see, for example, ref. 2), and the tritium will have decayed in geological time to helium-3. Helium-3 has been measured by mass-spectrometry in the helium from meteorites. If the ratio of helium-3 to helium-4 for helium produced by cosmic rays could be assessed accurately, then ages of meteorites could easily be calculated by the classical radioactivity method; but the ratio is dependent on the excitation energy of the iron nuclei which produce the helium and tritium by evaporation processes, and is therefore not constant at different points within meteorites. However, approximate limits to this ratio can be set in a number of ways.

Le Couteur[3] has predicted a ratio of the order of 0·3, and in helium from the meteorites so far examined the highest observed ratio is 0·315. A study of the variation of the ratio with depth in a large meteorite, "Carbo"[1b], showed a change in the ratio from 0·288 at a depth of 3 cm. to 0·277 for 29 cm. depth of iron. The helium content decreased also, and the values obtained theoretically by Martin[4] for the dependence on depth of the amount of helium produced by cosmic rays were in excellent agreement with the experimental values.

An estimate has been made by one of us[5] of the probable limits of the ratio helium-3 to helium-4 in the meteorites examined. The relative amounts o helium produced separately by primary and secondary radiation were calculated for points along a radius of an iron sphere, of size equal to the probable pre-atmospheric size of "Carbo". Since it is to be expected that the helium-3 to helium-4 ratio will decrease with depth as the mean excitation energy of the iron nuclei decreases[3], the measured values of the ratio ^{3}He/(^{3}He + ^{4}He) inside "Carbo" were plotted for the appropriate depths, against the ratio of helium due to primaries to helium due to primaries plus secondaries. The relationship was found to be linear, and, by extrapolating to 100 per cent primary radiation (that is, the value to be expected in a very small meteorite), the ratio of helium-3 to helium-4 was found to be about 0·4; and by extrapolating to 0 per cent primaries (that is, the inside of a very large meteorite, where only secondary radiation is effective) a ratio of about 0·25 was obtained. In "Carbo", at a depth of 29 cm. below the present surface, the observed ratio of helium-3 to helium-4 was 0·277; at this point, the production of helium would already be about 90 per cent due to secondary particles.

It has been pointed out by Bauer[6] that for meteorite samples which were once largely screened from

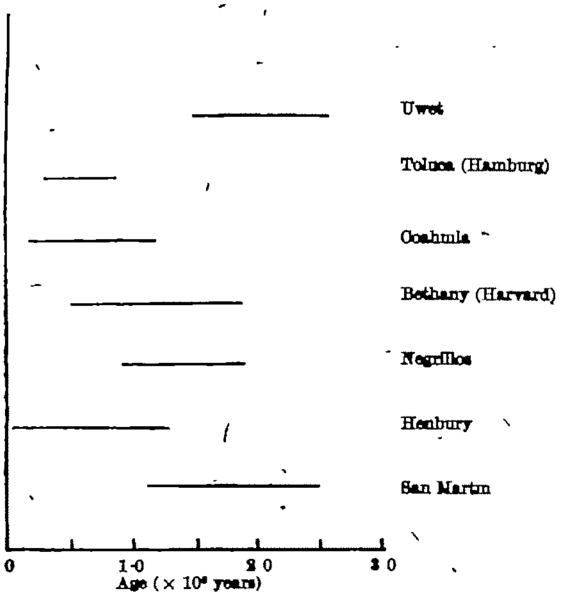
* Helium content in 10^{-6} c.c./gm. † Diam. in cm. calculated from recovered masses, assumed spherical. ‡ Type of fall: *M* = multiple, *S* = single. § Uranium and thorium contents in 10^{-8} gm./gm. ‖ Average value for twenty meteorites.

cosmic rays by an outer layer afterwards lost during passage through the atmosphere, the quantity of cosmic-ray helium will be inferior to that produced in small meteorites; in these samples the subtraction of this helium from the total cosmogenic and radiogenic helium can be made with greater certainty than in cases where the bulk of the helium is cosmogenic[1a,4].

In this investigation we have chiefly examined meteorites poor in helium with a ratio of helium-3 to helium-4 less than 0·31. We have assumed, on the grounds stated, that this ratio for helium from cosmic rays is between 0·40 and 0·25, and have thus calculated the radiogenic helium-4 contents. From the uranium and thorium contents, the probable ages have then been evaluated.

Helium was extracted from the meteorites and measured by a method previously described[7], and a mass spectrometric assay made of the helium-3 and helium-4 [8]. The methods of analysis of the uranium and thorium, present to the extent of 10^{-8} gm. per gm. of meteorite, can be found in the references shown in the table. The inherent difficulty in the uranium and thorium estimations, and the uncertainty in the ratio of helium-3 to helium-4, suggest that the age calculations should be made for maximum and minimum values. The maximum spread in age values has been obtained by combining the maximum uranium and thorium values with the value 0·25 for the ratio helium-3 to helium-4, and the minimum uranium and thorium values with the value 0·40 for that ratio. Three results previously published[10] have been added to this compilation. Results are shown in the table and in the graphical representation of the ages of the Group II meteorites. It appears that the maximum age for this group of meteorites is of the order of a few hundred million years. By a similar method a maximum age of 140 × 10^6 years for the meteorite Bethany (Harvard) has been deduced previously[10]. The subtraction method is oversensitive when applied to Group I meteorites.



It should be pointed out that for a meteorite which was originally very large, not only will the cosmogenic helium content be low, but there is also the possibility that the energy of the secondary particles has been reduced to such a value that the ratio of helium-3 to helium-4 is less than 0·25; it is concluded that the lower limits calculated by us are probably more uncertain than the upper limits. Calculations both on the upper and lower limits are difficult in view of the uncertainty about the initial sizes, shapes and velocities of the meteorites.

As insufficient helium for mass spectrometric assay was available from the Group III meteorites, their maximum ages have been calculated on the assumption that all the helium was radiogenic, using the mean uranium and thorium values. The meteorites in this group appear to be much younger than the others. The ages calculated, in million years, are: Savik, 0·4; Ahnighito, 1·1; Muonionalusta I, 1·3; Bethany Lion River, 3·6; Muonionalusta II, 30.

OBITUARY

Prof. William H. Woglom

CANCER research has suffered the loss of a pioneer, in the death at the age of seventy-four of Prof. William H. Woglom, at the Presbyterian Medical Center, New York, on August 8. Born in Brooklyn, Prof. Woglom graduated in 1901 from the College of Physicians and Surgeons, and after a period in medical practice in Manhattan became assistant in pathology at the Long Island College Hospital, and later pathologist and bacteriologist to the Department of Health. Between 1909 and 1946, at the Crocker Institute of Cancer Research, Columbia University, he was successively assistant, assistant professor, associate professor and professor emeritus, and in 1936 was specially honoured by the University for his conspicuous service. Prof. Woglom was president of the New York Pathological Society during 1924–26, of the American Association for Cancer Research in 1937, and from 1941 until 1946 he acted as a member of the scientific advisory committee of the International Cancer Research Foundation.

In his earlier career Prof. Woglom visited and worked in the laboratories of the Imperial Cancer Research Fund, and this happy association with Britain is reflected in certain joint publications; for example, with J. A. Murray on tar cancer[1], and with B. R. G. Russell on the respiratory exchange of surviving tissues of the mouse[2]. Prof. Woglom was specially devoted to questions of resistance and immunity, and published a paper in this field, on the immune reaction to transplanted cancer in the rat, in the *Proceedings of the Royal Society of London*[3]. Another early paper, of special interest in connexion with later developments in heterotransplantation, discussed tumour inoculation into the eye of an alien species[4]. However, in the list of Prof. Woglom's writings, pride of place should be given to his "The Study of Experimental Cancer: a Review"[5]; remarkable for its time, it still remains a valued classic. In later years he was author of "Discoverers for Medicine", an account of men who, although not physicians, had made important contributions to medicine; and he also translated into English Ernst Cassirer's "Problem of Knowledge" and Charles Oberling's "Riddle of Cancer".

Apart from his scientific accomplishment, mention must be made of other qualities—a generous and kindly nature, high sense of humour (often expressed in telling fashion in his writings and abstracts), extreme fairness and loyalty, and a devotion to literature and music—all of which combined to make him greatly loved by those who had the fortune to know him. He is survived by his widow, and by the children of an earlier marriage. ALEX. HADDOW

NEWS and VIEWS

Vice-Chancellorship of the University of Birmingham: Dr. R. S. Aitken

AFTER Sir Raymond Priestley retired last year from the vice-chancellorship of the University of Birmingham, Prof. H. F. Humphreys, formerly professor of dental surgery in the University, was asked to take over the post until a successor could take office. Although, shortly afterwards, Dr. R. S. Aitken, vice-chancellor of the University of Otago, Dunedin, New Zealand, was appointed to Birmingham, he was unable to take up the post immediately. Prof. Humphreys continued in office for a year until, quite recently, Dr. Aitken was free to take up his new appointment. Dr. Aitken, who was born in New Zealand, was educated at the University of Otago, graduating in medicine and surgery, and then in 1924 gained a Rhodes scholarship to Balliol College, Oxford, where he took a Ph.D. After medical work in the University of London, he was appointed in 1939 as regius professor of medicine in the University of Aberdeen, and it was during the Second World War that his exceptional administrative talents became well known when he took part in a survey of Scottish hospitals. Returning to his native New Zealand in 1948 as vice-chancellor of the University of Otago, Dr. Aitken was faced with the severe task of administering a university which was not only trying to make up for the lost war years but was also rapidly expanding, in keeping with the growing importance of the Antipodes. His services to Otago and also to the Federal University of New Zealand have been profound, and he takes up his duties in Birmingham with a reputation for university administration that is firmly established.

Vice-Chancellorship of the University of Otago, Dunedin: Prof. F. G. Soper, C.B.E.

DR. R. S. AITKEN has been succeeded as vice-chancellor of the University of Otago, Dunedin, by Prof. F. G. Soper, formerly professor of chemistry at Otago. Prof. Soper, who is fifty-five, was educated in Wales at St. Asaph Grammar School and the University College of North Wales, Bangor. After sixteen years as lecturer at Bangor, during which time he gained a D.Sc., he went in 1936 to New Zealand on being appointed professor of chemistry at Otago and shortly afterwards took on the additional responsibility of being director of the New Zealand Woollen Mills Research Association. During the Second World War he served as deputy director of scientific development (chemical) of the New Zealand Department of Scientific and Industrial Research, and he is at present a member of the Defence Science Advisory Committee of that country. As a member of the Academic Board and Senate of the University of New Zealand, Prof. Soper has been closely connected with recent developments in university education in New Zealand and has also given much time to the technical and professional advancement of science, being a past president of the New Zealand Institute of Chemistry and of the Royal Society of New Zealand. Consequently his appointment as vice-chancellor of Otago is singularly apposite and augurs well for the future of the University. He was made a C.B.E. in 1950.

Fisheries Research Vessel *Alister Hardy* of the Fisheries Research Unit, University of Hong Kong

IN previous references in *Nature* to the work of the Fisheries Research Unit of the University of Hong

ong (see *Nature*, 170, 789 (1952), and 172, 886 953)), mention has been made of the building of a ssel for conducting fisheries research in the waters ljacent to Hong Kong. This vessel was launched n November 7 by Lady Grantham, wife of the overnor of Hong Kong, and was named the *Alister ardy* in honour of Prof. A. C. Hardy, Linacre prossor of zoology in the University of Oxford, who as present at the ceremony. The *Alister Hardy*, though not a large vessel, is one of unusual interest. nto her length of 66 ft. and beam of 17 ft. 10 in. it as been possible, by careful designing and planning, incorporate all the equipment which will be quired by the Fisheries Research Unit for its work t sea. In addition to the usual accommodation for fficers and crew, there will be, in the forward part f the vessel, a fully equipped laboratory for scientific ork in connexion with the examination and classication of sea life to be carried out immediately the ecimens are obtained. To assist in this work there re special desks, provided with illuminated panels, nd also a large electric refrigerator with twin comartments; one of these will be set at just above eezing point and the other just below. There will lso be a salt-water tank, with circulated water, for eeping specimens alive. The vessel will be propelled y a Crossley diesel engine, developing 130 b.h.p. at ,350 r.p.m., driving through a gearbox a reversibleitch propeller manufactured by Messrs. Slack and arr, both the speed of the engine and the pitch of he propeller being controlled from the wheelhouse; his arrangement is very important, as so often in a iesel-engined vessel it has been found impossible to et a continuous very slow speed which is essential or the successful use of some of the fine planktonatching nets. As Prof. Hardy remarked in a speech fter the launching, nothing is really known of the hysics and chemistry of the Hong Kong waters or heir fundamental biology—the factors which may e all-important in understanding the lives of the sh: the current systems, the varying saltness of the water, the changing distribution of the small life of he sea, on which the fish feed, and so on; every ruise of the *Alister Hardy* may well be a voyage of iscovery.

xpansion of the Department of Scientific and Industrial Research

In reply to questions from Mr. F. Lee and Sir Wavell Wakefield in the House of Commons on December 8, Mr. J. R. Bevins stated that a general understanding which has been reached between the Department of Scientific and Industrial Research and the Treasury provides for the gradual expansion of the Department's activities over the next five years, subject to necessary reservations and the voting of the necessary funds. A programme is envisaged on the basis of which the total resources of the Department should, by 1959, be adequate to cover 95 per cent of the activities projected in the plans covered by the 1947–48 Report, together with some additional responsibilities since taken over from other Departments. Also involved are an increase in staff of a thousand to a total of just more than five housand, an increase of £900,000, or about 20 per ent of the annual net vote over that period, and a building programme (the cost of which will be borne on the vote of the Ministry of Works) of about £6,000,000. In addition, means will be sought for naking good in the plan during later years any leficiencies in expenditure which occurred during the earlier years due to unforeseeable delays in the fulfilment of any planned developments. All estimates of the Department will be presented to Parliament in the usual way.

Higher Technological Education in Great Britain

REGARDING the establishment of a College of Technology, on which questions were asked in the House of Commons on December 8, Mr. R. A. Butler stated that, as announced on January 27, the Government proposes to develop higher technological education in London by building up the Imperial College of Science and Technology. Outside London the University Grants Committee has invited universities and colleges on its grant list, which are concerned with higher technological education, to submit their plans for development. When these plans have been received and examined, a further statement will be possible. Meanwhile, Mr. Butler indicated that Manchester is well in the running for a further place, and an institution in Scotland is also envisaged. In reply to Mr. Woodburn, he agreed that these technological institutions could contribute to the development of scientific discoveries in Britain which at present are exploited abroad, but that the technical colleges also could contribute.

IN a written reply on December 17 to a question in the House of Commons, Miss Horsbrugh, Minister of Education, stated that the governing bodies of the College of Aeronautics, Cranfield, and the Loughborough College of Technology have each accepted £50,000 to endow a senior teaching post in industrial engineering from the £130,000 allocated for technical education in Counterpart Funds. A sum of £15,000 will be spent in scholarships for persons engaged in industry to enable them to attend courses in work study at these or other suitable educational establishments. While the Minister of Education will be responsible for the disposal of these grants, the Minister of Labour will be responsible for further grants amounting to £15,000, which has been allocated for scholarships in personnel management.

Changes of Outlook in England during the past Hundred Years

ON October 23 Lord Samuel gave the Hibbert Lecture in Cambridge marking the centenary of the Trust founded by Robert Hibbert to promote "the spread of Christianity in its most simple and intelligible form" and "the unfettered exercise of the right of private judgment in matters of religion". The Lecture, which was entitled "A Century's Change of Outlook", has been published as a booklet (pp. 22; Cambridge University Press, 1953; 2*s*. 6*d*. net). Lord Samuel surveyed the intellectual, moral, political and economic condition of England a hundred years ago and compared it with the present day. He finds that much has happened of which Hibbert would have approved, though some of the changes have been too rapid for safety, and the prospect of further progress is uncertain. Progress calls for great efforts, above all "to develop a living growing body of thought, at once philosophic, scientific and religious", as a guide to our own and future generations.

United States Federal Research and Development Funds

A FURTHER study by the National Science Foundation of the United States Federal Research and

Development Budget for the fiscal years 1952 and 1953 has been published as No. 2 of the series "Federal Funds for Science" (pp. 44. Washington, D.C.: Nat. Sci. Found., 1953). This study, which is based primarily on data supplied to the Foundation by the twenty-four agencies administering such activities, estimates Federal expenditure on scientific research and development in the year ended June 30, 1953, as 2,200 million dollars, an increase of 400 million dollars on the previous year. Commitments were estimated at 2,400 million dollars as against 2,200 million dollars in 1952, but the rate of increase is slackening, and it is expected that both commitments and expenditure will decrease during the fiscal year ending June 30, 1954. It is estimated that about 25 per cent of the expenditure is on work carried out in government-owned installations, 15 per cent on work sponsored at non-profit institutions, and 60 per cent on work sponsored at business organizations. In 1952, twenty-four agencies, and in 1953, twenty-two agencies, administered programmes of research and development, but, of these, seven agencies administered almost 99 per cent of the funds, the Department of Defense accounting for more than 76 per cent and the Atomic Energy Commission for more than 10 per cent of the commitments. Only some 6 per cent of the commitments are for basic research: 121 million dollars in 1952 and 126 million dollars in 1953, 29 per cent of this amount, moreover, being administered by the Atomic Energy Commission. Funds for the physical sciences accounted for 90 per cent out of the total, 7–8 per cent going for work in the biological sciences and the remainder for work in the social sciences. Since 1940, Federal expenditure on research and development has increased more than 22 times, from 97 million dollars to 2,200 millions, the proportion of the Federal budget expended on research and development having also increased, from 1·1 per cent in 1940 to about 3 per cent in 1953.

Medical Research in the United States

THE growth of medical research in the United States during 1941–53 and of the role of Public Health Service Research Grants are indicated in a review by K. M. Endicott and E. M. Allen (*Science*, 118, 337; 1953). They point out that during the decade 1940–50 expenditure on medical research increased about tenfold, and the Federal Government emerged as a major source of financial support, contributing very little to the total of 18,000,000 dollars in 1941, but 28,000,000 dollars out of 115,000,000 dollars in 1946 and 76,000,000 dollars out of 181,000,000 dollars in 1951. Industry provided 55,000,000 dollars in 1946 and 60,000,000 dollars in 1951. The pool of trained man-power also increased considerably, as did the output of scientific publications. The tendency to concentrate medical research in some dozen large centres was reversed and several powerful new foci of research appeared. The Research Grants Programme of the Public Health Service really began in 1946 with the transfer of fifty projects from the Office of Scientific Research and Development when that agency was dissolved, although the Service had awarded a few grants for cancer research each year since 1937. The new programme had as its objective the improvement of the nation's health through the acquisition of new knowledge in all the sciences related to health, and, in so far as the new knowledge is sought for the purpose of improving health, the programme is one of applied research. However, many of those receiving grants regard their projects as basic, and policies and procedure unde the programme have been designed to ensure the maximum freedom to those scientific workers who receive grants. Full freedom of publication is given and once a grant is made there is no direction o interference on the part of the government. Although in 1951 the Public Health Service research gran programme accounted for only 8·8 per cent of the expenditure on medical research, Endicott and Allen consider that the programme has been of the greates assistance to institutions able and willing to employ and provide basic facilities for competent scientific workers. Some 35 per cent of the funds, or nearly 35,000,000 dollars, between 1946 and 1953 went on professional assistants to those receiving grants, and many of these assistants themselves now receive grants. Another major effect of the programme has been to stimulate research in neglected fields, particularly research on some of the chronic diseases

Conflicts of Loyalty

THE "Present Question" Conference at Oxford in 1952 on "Conflicts of Loyalties" was concerned with a wider range of problems than its title suggests. The addresses and discussions of most immediate interest to the man of science—those concerned with problems bearing on the conflict of loyalties which may arise out of his professional pursuit of truth and the demands of national security or between religion and science—were reported in the winter 1952 issue of *Question*, which included the papers of H. Westmann on conflicts of loyalties, of Prof. M. Polanyi on science and faith, of Herbert Reid on sign and symbol and of Dr. J. H. Oldham on man and truth. The remaining papers and discussions, which are given in the spring 1953 issue of *Question* (5, Nos. 2–3; pp. 152. London: Hammond, Hammond and Co., Ltd., 1953; 7*s*. net), are of much slighter scientific interest, although Angus Maude in his address on morals and politics faces the same issues that Prof. A. V. Hill raised in his presidential address to the British Association shortly afterwards. Generally speaking, these addresses range from the conflicts between the artist's loyalty to the creative impulse and society, between patriotism and world community, between country and party, between functions and personality and between the individual and the family; generally speaking, they stress the importance of human relations and point to the resolution of the problem of relations between the individual and the family or the group, or the larger units of which industry, society and the international community are built up, as holding the key to the elimination of conflicts of loyalty.

Comparative Studies of Apices

IN a recent paper (C. W. Wardlaw: "Comparative Observations on the Shoot Apices of Vascular Plants", *New Phytol.*, 52, 3, 195; 1953) it is held that while such new types of histological organization as may be observed in the shoot apices of vascular plants will carry their own interests, the extensive anatomical and histological data which are now available should be studied from the genetical, physiological, physical and mathematical points of view, with the view of discovering the causes underlying the homologies of organization which they show. From a comparative examination of apices, all reproduced at the same magnification, it is inferred that the size and metabolism of the meristem cells of the apex are gene-determined, out to understand the characteristic histological organization of any apex, both cellular properties and the distribution of growth in the apex as a whole must be considered. Various factors which may affect the histological constitution of the apex, he distinctive character of the apical cell, or apical ell group, in different species, and some geometrical properties of zoned apices are discussed. The entative conclusion is reached that the homologies of organization, shown by shoot apices at large, may be due more to extrinsic factors and relationships han to genetical factors, although, in fact, both ets of factors work together to produce the observed results.

The Freshwater Biological Association

THE twenty-first annual report of the Freshwater Biological Association contains the usual summary of the scientific work of the staff. Dr. C. H. Mortimer, the hydrologist, has analysed water temperature ecords from various depths in the two basins of Windermere and confirms that, when compared with wind records, internal waves of a wide range of frequencies are generated during windy weather and die away during calms, but that the wave which is most readily set in motion and persists longest is the single 'see-saw' motion of the thermocline plane. The periodicity of this wave can be calculated for any given example and compared with the periodicities observed, either by inspection of long series of temperature records or, more precisely, by a frequency analysis of them. This comparison has now been extended to ten lakes for which sufficient data exist, ranging in (medial) length and calculated period from 1·5 km. and four hours in the case of the Lunzer Untersee, to 73 km. and four days in the Lake of Geneva.

The algologist, Dr. J. W. G. Lund, has completed a seven-year study of the periodicity of the diatom *Melosira italica*, and shown that this can be related to the occurrence of floods, variations in the amount of light penetrating the water, differences in lake morphology, and water movements, both direct and inverse thermal stratification playing a fundamental part. Moreover, the size of the population in one year may influence that developed in the next. Among work undertaken by other members of the staff was the completion of a survey of the effects of fungal parasitism on the periodicity of plankton diatoms, further investigations into the distribution in lake muds of the two groups of bacteria which reduce sulphates and oxidize thiosulphates, investigation of the morphology of *Desulphovibrio desulphuricans*, marking experiments to determine the details of behaviour of char during the spawning season and an inquiry into the seasonal changes in the activity of the thyroid gland and in the chemical composition of the muscle, liver, gut and gonads of the brown trout.

The Night Sky in January

NEW moon occurs on Jan. 5d. 02h. 21m., U.T., and full moon on Jan. 19d. 02h. 37m. The following conjunctions with the moon take place: Jan. 16d. 01h., Jupiter 4° S.; Jan. 27d. 13h., Saturn 8° N.; Jan. 28d. 15h., Mars 6° N. In addition to these conjunctions with the moon, Mars is in conjunction with Saturn on Jan. 2d. 21h., Mars being 1·3° south. Mercury, a morning star during the first half of the month, is too close to the sun for observation and is in superior conjunction on January 14, after which it is an evening star, setting at 17h. 40m. at the end of the month, about an hour after sunset. Venus, a morning star, is too close to the sun to be observed and is in superior conjunction on January 30. Mars, a morning star, rises at 2h. 50m., 2h. 40m. and 2h. 25m. on January 1, 15 and 31, respectively; its stellar magnitude varies from 1·6 to 1·2, and during the month it moves from a little south of κ Virginis to south of γ Libræ. Jupiter, visible throughout the night, sets in the morning at 6h. 35m., 5h. 30m. and 4h. 20m. at the beginning, middle and end of the month, respectively; stellar magnitude −2·3 to −2·1; its slow westward movement from near ζ Tauri can be noticed during the month. Saturn is a morning star, its times of rising on January 1, 15 and 31 being 2h. 45m., 1h. 55m. and 0h. 55m., respectively, stellar magnitude 0·8–0·7. Occultations of stars brighter than magnitude 6 are as follows, observation being made at Greenwich: Jan. 2d. 9h. 08·5m., α Scorp. (*D*); Jan. 2d. 10h. 26·6m., α Scorp. (*R*); Jan. 13d. 22h. 23·5m., ε Arie. *m* (*D*); Jan. 14d. 17h. 09·4m., 27 Taur. *m* (*D*); *R* and *D* refer to reappearance and disappearance, respectively. The earth reaches perihelion on Jan. 2d. and the Quadrantic meteors are active on January 2 and 3. On January 5 there will be an annular eclipse of the sun, invisible at Greenwich. During January 18–19 there will be a total eclipse of the moon, the circumstances of the eclipse being as follows:

Moon enters penumbra	Jan.	18d.	23h	39 6m.
Moon enters umbra		19	00	50·0
Total eclipse begins		19	02	16 6
Middle of eclipse		19	02	31·8
Total eclipse ends		19	02	46 9
Moon leaves umbra		19	04	13 5
Moon leaves penumbra		19	05	24·1

Announcements

THE Institute of Metals has awarded the following Medals for 1954: *Institute of Metals (Platinum) Medal*, to Dr. Leslie Aitchison, in recognition of his services to metallurgy in industry, in education and in public service; *Rosenhain Medal*, to Prof. A. H. Cottrell, professor of physical metallurgy in the University of Birmingham, in recognition of his outstanding contributions to knowledge in the field of physical metallurgy, with special reference to the deformation of metals.

THE following have been appointed to lectureships in The Queen's University of Belfast: Dr. H. G. Heal (chemistry), Mr. J. G. Stuart (soil mechanics), and Dr. J. Lowy (experimental zoology).

DR. J. F. MCCREA writes: "My attention has been directed by Dr. Alfred Gottschalk to an omission in the final paragraph of my communication, 'Turbidity-reducing Activity of Influenza Virus and Receptor-destroying Enzyme on Sheep Submandibular Mucoid' (*Nature*, 172, 912; 1953). The sentence referring to the split-products released from mucoproteins after incubation with influenza virus should read: 'An N-substituted fructosamine (*iso*glucosamine) is liberated as an end-product of the interaction between influenza virus and the purified ovomucin or electrophoretically homogeneous urinary mucoprotein substrates (Gottschalk, *Nature*, 167, 845; 1951)' ".

ERRATUM. In the communication "Interstitial Atoms in the Layer Structure $ZnMn_3O_7,3H_2O$ (Chalcophanite)" by A. D. Wadsley (*Nature*, December 12, p. 1103), line 3 should read "$\alpha = 90°$, $\beta = 117·2°$, $\gamma = 120°$".

THE ROYAL SOCIETY OF CANADA

THE Royal Society of Canada held its annual meeting at the University of Western Ontario, London, Ontario, during June 1–3. The scientific sections met separately as is the custom.

Section III (Chemical, Mathematical and Physical Sciences)

The presidential address was presented by Prof. R. L. Jeffery, who described the historical development and the impact of Fourier series on applied and pure mathematics. This was followed by a description of applications of Fourier series in physical problems (W. H. Watson), which together with the presidential address provided an informative and stimulating symposium on a subject of interest to all members of the section.

Following this symposium, the section divided into sub-sections to hear and discuss a total of 122 papers, arranged under the headings of spectroscopy and astrophysics, chemistry, mathematics, nuclear physics, general physics and solid state physics. The papers selected for presentation were not confined by a rigid definition of these headings, and therefore members of the Society were given an excellent review of the main fields of investigation being actively explored at the various research centres across Canada.

Spectroscopy and Astrophysics. This sub-section discussed fifteen papers on molecular spectra, hyperfine structure, Raman spectra, and the interpretation of certain stellar spectra. It included two theoretical papers, one on the calculation of vibrational transition probabilities and the other on the calculation of the dipole moment induced in an H_2–H_2 system during collision.

Chemistry. This sub-section, meeting in two sessions, was presented with twenty-six papers. A group of papers describing the successful synthesis of new series of pyrazolones and metameconine compounds, together with further synthesis of organic deuterium compounds, represented the work in this part of chemistry. Six papers dealt with various aspects of radioactive chemistry, isotopic constitutions and the occurrence of nuclear processes in Nature. Electrochemical studies on resin emulsions, ethyl chloride and the effect of adsorbates on activated carbon were described. The chemical kinetics of gas phase reactions, thermal decomposition, ion exchange and the quenching of resonance radiation were reported. A very complete study of the peats found in Quebec regarded as a potential source of chemical raw materials provided the desirable link with industrial chemistry. A discussion of the orbital valence theory and a description of the motions and interactions of spheres and cylinders suspended in a liquid subjected to a velocity gradient were of particular interest to members of the other sub-sections.

Mathematics. The fourteen papers presented to this sub-section included six presentations of new theorems and properties relating to various topological and function spaces. In particular the theor of *L*-spaces was considerably extended. Addition to the modular representation theory and the gener properties of groups under substitution of forma power series, a discussion of absolute summabilit functions, hypergeometric functions, and two paper on further generalization of the Laplace transform method gave a sampling of the current interests i pure mathematics. The multiplicity of representations in sets of integers was discussed in two papers Ordinary physical space received attention when i was shown that a classical theorem is equivalen to the fact that the closest possible packing o equal spheres about lattice points occurs when th centres form the face-centred cubic lattice.

Nuclear Physics. This sub-section received thirty eight reports, of which twenty-six were read at it two sessions, and the remaining thirteen reporte by title. The wide variety of techniques an reactions used, nuclei studied and properties measure preclude any convenient classification of the papers

The results of cosmic ray studies were reported i four papers while two others presented problems o particle identification in photographic emulsions Descriptions of new technical advances included a apparatus for the observation of spin echoes, th stabilization of a Van de Graaff generator, a single crystal scintillation spectrometer, a three-crysta pair spectrometer, coincidence circuits with resolving time of $\sim 10^{-11}$ sec. and an improved beta-ray spectrometer.

A description of neutron diffraction in liquid oxygen, nitrogen and argon, the successful testing of a new method of nuclear spin determination and five theoretical papers on coupling, resonance, spin and magnetic moment calculations completed the programme of this sub-section.

General Physics. Of the twelve papers presented to this sub-section, eight dealt with radio physics problems: radio investigation of the aurora, solar noise, design of filters, effect of matching on crystal parameters, microwave diffraction and microwave spectroscopy. Members were shown that the thickness of irregularly shaped particles determined by shadow-casting methods is not necessarily accurate. Three papers were reported by title.

Solid State Physics. The fourteen papers presented to this sub-section included all those devoted to low-temperature theory and problems; four on studies concerned with liquid helium, two on superconductivity, paramagnetic resonance and thermoelectricity. Other theoretical papers described an alternative solution to the Ehrenfest problem, the effect of assumed anharmonicity in the classical linear chain with nearest-neighbour interaction, the reverse saturation current of germanium rectifiers, the self-consistent field of Au^+, and the relation of vapour density to snow crystal type. Reports on the tensile strength of liquid nitrogen and observations of the pattern of snow trails in seeded showers were given.

A. D. MISENER

Section IV (Geological Sciences)

The twenty-one papers given before Section IV included most branches of the geological sciences. J. T. Wilson discussed the earth as a heat engine, and its operation under the laws of physics; J. A. Jacobs reviewed the composition of the core of the earth and how it could have become solid through loss of heat by convection, though only conduction appears necessary. Some characteristics of grabens, rifts, major wrench faults and straight island chains, their agreement with E. M. Anderson's explanation of wrench faults and their occurrences were discussed by J. T. Wilson. H. S. Heaps gave a theoretical analysis of 'downpunching', with the stresses produced in the outer crust of the earth by the weight of a cylinder on its surface, and showed that some of the results apply to the load imposed by an ice cap. The interpretation of structural features, seen in aerial photographs of south-eastern Ontario, was discussed by A. Burlinson. E. S. Moore gave an account of the structural history of the Porcupine Gold area revealed by detailed mapping.

Two papers described glacial features mapped from aerial photographs in the vast territories of the north and their interpretation, that by M. J. Downie, A. G. Evans and J. T. Wilson dealt with the region between the Mackenzie River and Hudson Bay, while that by M. C. V. Douglas and R. N. Drummond covered Ungava.

Three papers were devoted to the determination of the ages of rocks: first, an account of the branching ratio of potassium-40 by R. D. Russell, H. A. Shillibeer and A. K. Mousuf; second, the determination of the ages of lead ores from their isotopic constitutions, by R. M. Farquhar, R. D. Russell and J. T. Wilson; and third, the isotopic constitution of the Sudbury galenas, by R. D. Russell, R. M. Farquhar and G. L. Cumming. J. F. Henderson gave a new and more complete explanation of the formation of pillow lavas and breccias of the Precambrian Shield. M. E. Wilson described the pre-Timiskaming unconformity in the Rouyn–Beauchastel area. C. Faessler described the surface alteration of some ore deposits from Montmagny and Bellechasse counties, Quebec, and some rare minerals from them. The origin and structure of the pyritic ore-bodies of Algoma, east of Goudreau, and their connexion with the Algoma granite, were discussed by G. V. Douglas. An account of the origin of the Nova Scotian gypsum and anhydrite deposits was given by N. R. Goodman.

The paper by H. V. Warren, R. E. Delavault and D. G. Routley described the detection of traces of molybdenum in vegetation growing where the rocks contain the metal. A. R. Byers demonstrated that the Missi Series of the Amisk Lake area, northern Saskatchewan, was probably laid down during the folding of the underlying rocks. A paper of great importance in Precambrian geology was that by J. E. Thomson. This paper shakes the foundation of present conceptions of the Precambrian stratigraphy in the region west of Sudbury, which has long been regarded as a type and classical section of the Precambrian in North America. It focuses a critical light upon the past work in the region, and offers constructive ideas as to how the problems raised may be tackled. F. F. Osborne described a peculiar concretion conglomerate in the Charny sandstone and discussed its origin. L. S. Russell described the discovery of a new freshwater fauna, including terrestrial gastropods and small mammalian forms, and showed that it dates the Kishenehn formation of south-eastern British Columbia as uppermost Eocene and necessitates some revision of ideas on the history of the southern Rocky Mountains of Canada.

H. S. Bostock

Section V (Biological Sciences)

W. A. Clemen's presidential address on "Some Fundamental Problems in the Biology of Pacific Salmon" dealt with the systematics, phylogeny, distribution and migrations of *Oncorhynchus*. In discussing migration, the author referred particularly to endocrine and associated behaviour-pattern changes in relation to cyclic environmental factors. E. G. D. Murray's Flavelle medallist's address "The Story of Listeria" indicated problems in comparative pathology, physiology, biochemistry of lipids and histogenesis of mononuclear leucocytes arising from the discovery of a bacterial disease characterized by monocytosis, focal necrosis and œdema, occurring on all continents and in nineteen animal species (including man) in various somewhat species-restricted forms without differentiation of the causative bacterium. Three other papers were also delivered at the first general session. "On the Nutritional Requirements of Young Children", by T. Allen, A. V. MacLeod and E. G. Young, reported conclusions from two surveys comprising 156 children 1–6 years of age, in which nutrition assessed from physical, anthropometric, laboratory and radiographic observations was correlated with dietary consumption of essential nutrients. P. Dansereau discussed "Interpretation of the Post-glacial Pine Period in Eastern North America". He considered alternative hypotheses, respectively attributing stages of abundant *Pinus* pollen during this epoch to environmental factors and to adaptation of the prevalent species, and then reviewed the evidence provided in six specific instances, by geology, climatology, evolution, genetics, taxonomy, ecology and sociology. Finally, W. Radforth, in "The Use of Plant Materials in Recognizing Northern Organic Terrain Types", described microfossil studies combined with form analyses of associated living vegetation as aids in the accurate classification of terrain for ground and air mapping.

The second general session consisted of a symposium on "Recent Approaches to the Control of Diseases and Pests in Plant and Animal Life". H. Martin reviewed chemical contributions resulting from the discovery and delimitation (particularly in respect of mammalian toxicity) of biological activity in synthetic compounds, exemplified by DDT and 2:4-D. J. M. Cameron discussed the variable results achieved in forest insect control by chemicals and by biological methods, utilizing sylviculture, parasites and predators. F. B. Hutt illustrated the importance of genetic differences in resistance of animals (including man) to infection, and their relation to the control of specific diseases. E. G. D. Murray selectively reviewed recent advances in medical bacteriology, indicating some findings of general biological significance. He also suggested lines of fruitful investigation, such as determination of the specific cellular functions affected by antibiotics.

In a short summary, reference can be made to only a few of the more specialized papers presented at the meetings of sub-sections. In botany and zoology, G. N. Irvine, W. Bushuk and J. A. Anderson reported first-order reaction kinetics for crude catalase extracts from wheat which, unlike the crystalline enzyme, were not activated by the hydrogen peroxide substrate. P. V. Vittorio and G. Krotkov discussed the synthesis of sucrose and starch in detached tobacco leaves infiltrated with carbon-14-labelled glucose and glucose-1-phosphate. They concluded that the fructose moiety of sucrose arose from infiltrating glucose and not from free fructose, but that infiltrated radioactive sugars contributed only a small amount of their activity to starch.

D. E. Wells reported the discovery of *Ascocybe*, a new genus of primitive *Ascomycetes*, as a common saprophyte on wood, while M. Raymond described a noteworthy new hybrid between *Eriophorum angustifolium* and *E. chamissonis*. L. Butler summarized the results of an experiment with large and small strains of mice involving inbreeding and selection to increase the size of the former strain and decrease that of the latter. No effect of inbreeding on vigour was noted. In the large strain, experimental selection was neutralized by opposed effects of natural selection. In the small strain effects of natural selection were dominant, and body-size actually increased in each generation.

In physiology and medical sciences, W. R. Campbell described a new method of photometric estimation of serum calcium, based on Schwarzenbach's reaction and promising routine rapidity and precision. E. T. English and R. L. Noble demonstrated that although either periodic acid or an aqueous extract of *Lithospermum coroeum* may induce inactivation of human chorionic gonadotrophin *in vitro*, the mode of inactivation differs when judged by histological examination of the ovaries of treated animals. W. H. Cook and C. V. Luzena discussed ice propagation in model systems of solutions and membranes, in relation to the ability of living cells to survive freezing. Discontinuous behaviour is favoured by low membrane porosity, rapid cooling and increased concentration of solutes in the aqueous phase; supercooling and nucleation ahead of the ice front can be demonstrated in sucrose and gelatin solutions. C. A. Mitchell presented data indicating that at least two viruses can propagate themselves within the bovine mammary gland; resulting locally produced neutralizing antibodies may be found in both the blood and milk serum. J. Tuba and M. I. Robinson reported that rat intestinal alkaline phosphatase consists of an adaptive portion varying with the dietary state and a non-adaptive fraction remaining constant even during prolonged fasting; the former is probably translocated lymphatically during fat absorption, thus elevating serum phosphatase levels. A. H. Hutchinson, V. H. Turnbridge and M. Elvin submitted photomicrographic evidence for mitosis, syngamy and meiosis in *Bacillus subtilis* (the cytological cycle being completed in two hours at 40° C.), and compared the observed structural detail of euchromatic progression with the cytology of other forms.

N. H. Grace
J. W. Hopkins

New Fellows

Six new fellows were elected to Section III: G. A. Adams, H. J. Bernstein, I. Halperin, M. Kulka, M. S. Macphail, J. S. Marshall; four to Section IV: N. Campbell, Y. O. Fortier, J. W. Watson, L. J. Weeks; and six to Section V: J. A. Dauphinee, C. C. Heimburger, A. G. McCalla, J. H. Orr, J. H. Quastel, E. H. Strickland.

PHOTOELECTRIC RAINDROP SPECTROMETER

Determination of the frequency distribution of the diameter of raindrops in relation to the rate of rainfall is an important problem of meteorological measurement. Knowledge of this distribution is important in the major scientific problem of the formation of raindrops and in such practical matters as protection of aircraft from ice accretion. Several methods have been used hitherto, such as measuring the size of the pellets formed when the drops fall into fine flour, the diameter of splashes on filter paper, or the magnitude of the noise produced when the drop hits a microphone. All had serious disadvantages, such as uncertainty of calibration or lack of flexibility in use in natural rain in which the rate of fall sometimes changes quickly.

Now, in the October number of the *Quarterly Journal of the Royal Meteorological Society*, B. J. Mason and R. Ramanadham, of the Department of Meteorology, Imperial College of Science and Technology, London, describe an entirely new apparatus—the photoelectric raindrop spectrometer—which is based on the scattering of light by the drops. A parallel beam of light of horizontal axis is produced, and the drops falling through a rhombus-shaped section in this beam of area 72 cm.^{2} scatter light into the cathode of a photo-multiplier cell. The voltage produced by the light pulse is suitably amplified and recorded and the results interpreted from calibration with drops of known size. The apparatus has the great advantage that it records continuously and takes account without difficulty of obliquely falling drops and of changes in the rate of fall. The probability of two drops falling through the area in natural rain at the same time to give overlapping impulses on the recorder is so small that it can be entirely neglected.

A comparison of this new apparatus with older, more clumsy methods has shown very good agreement. A few records are given in the paper. A series taken during showers shows that the drop-frequency curve had two modes in the heavier rain. The rates of fall varied from 2·43 mm./hr. to 0·22 mm./hr. All had a mode of drop-diameter at 0·9 mm.; the 0·22 mm./hr. rain had no second mode, and the second modes were 1·4 mm. for the rate of 0·66 mm./hr., and 1·6 mm. for the rates of 1·26 and 2·43 mm./hr. The amount of rainfall recorded by a rainfall recorder over several minutes during a light shower and the amount deduced from the spectrometer readings agreed to within 5 per cent. The raindrop spectrometer is to be used in conjunction with a 3-cm. radar in the study of condensation processes.

NATIONAL CENTRAL LIBRARY, LONDON

REPORT FOR 1952–53

The thirty-seventh annual report of the executive committee of the National Central Library, London, covering the year ended February 28, 1953, records an increase in the Treasury grant-in-aid from £27,250 during 1951–52 to £31,250. The funds at the Trustees' disposal were insufficient to cover the cost of the essential reinforcements in the east wing of the building. The Carnegie United Kingdom Trust, when appealed to, made a special grant of £7,500, as well as one of £750, towards the survey of the regional library systems and the National Central Library.

A joint working party, the terms of reference of which were expanded to include further aspects of inter-library lending, completed its work during the year, and its report was received by the executive committee in 1952, when the recommendations were submitted forthwith to the regional library executive committees for comment. A sub-committee of the joint standing committee on library co-operation has undertaken a project under which certain university and other libraries have agreed to co-operate, by purchases within certain periods of years, in filling gaps in British secondary or 'background' literature which is in increasing danger of being sold abroad. Returns have been made of several thousand holdings in many of the greater public libraries and university libraries.

Compared with 1951–52, issues of books from or through the Library increased by 1,105 to 99,413, issues through university libraries and special outlier libraries increasing from 16,997 and 9,798, respectively, to 18,040 and 10,198, while those through municipal libraries and industrial and research organizations decreased, from 26,569 and 5,828 to 23,630 and 5,746, respectively. Total applications decreased slightly (from 101,383 to 100,049), but the percentage of applications handled successfully increased from 68·27 to 71·21. Issues from the Scottish Central Library increased from 15,708 to 16,349 and from the Irish Central Library for Students from 12,089 to 12,450. Outlier libraries now number 225 and lent 24,478 volumes during the year. Books supplied by the regional system to other libraries in their own regions generally decreased, but university libraries, apart from loans under the national system, lent 23,905 books to other libraries during the year, compared with 21,965 during 1951–52. International loans also increased: 2,154 books were lent to 38, and 1,026 books borrowed from 21, countries. Progress is also reported in the National Union Catalogue and the Union Catalogue of Russian Books and Periodicals, and the Sheaf Catalogue for German War-Time Books was completed.

FORESTS OF THE BELGIAN CONGO

UNDER the title of "Forest Species and Timbers of the Congo" the Institut National pour l'Étude Agronomique du Congo Belge is publishing a monograph of which the first part has now appeared*. This part, which is an introduction to a study of the botanic and forest characteristics of species of the Congo forests, points out that Belgian forests alone can only supply a little more than half her timber requirements; and as they are chiefly conifers they cannot provide for such necessities as construction and furniture, etc. Belgium has therefore to depend, in the same way as Britain, largely upon foreign markets, Scandinavian and United States, for the rest of her requirements. This has brought to the notice of a section of the public and to the Belgium Government that the Belgian Congo is one of the countries which possess the greatest areas of dense forests on the globe; for all the central part of the Belgian Congo is covered with the great equatorial forests of Central Africa, and these are estimated to amount to 125 million hectares, consisting of the diversity of species found in mixed tropical forests and representing, says the monograph, milliards of cubic metres of timber.

At first sight it would be asked why has this great source of timber wealth not been already drawn upon? The answer, it is stated—and the British began to discover this for the tropical forests more than a century ago in India—is found in the inaccessibility of the forests, difficulties of exploitation, extraction and transport; but a start has been made. As was also found in India, there are difficulties in introducing new tropical timbers on the world markets, conservative timber merchants, architects and other users of timber being against such new importations.

The first question posed, however, is the necessity of knowing the botanic contents of the forests; and the second, whether a timber species of marketable value exists in sufficient abundance in a section of the forest to make its exploitation a commercial success. Also, as Bertin, a French forest officer of considerable African experience in the Ivory Coast and elsewhere during the First World War and after, said in his "La Question Forestière Coloniale" (Paris, Larose, 1919): "Impossible de s'intéresser à des bois dont on ignore même le nom". It is considered, and probably correctly, that the Congo forests are not enough to provide for all the requirements of Belgium both in quantity and quality.

This monograph is being prepared with that object in view. It has the double purpose, botanic and forest, and will provide in subsequent parts a botanic and physical description of each species dealt with, followed by the mechanical and technological properties of the timber. In fact, much of it is on the lines of Gamble's "Manual of Indian Timbers" first published in the latter part of last century. This first part of the Belgian monograph is confined to general principles only.

E. P. STEBBING

MOTOR RESPONSES EVOKED BY THE DORSAL OCELLI OF *SARCOPHAGA ALDRICHI* PARKER, AND THE ORIENTATION OF THE FLY TO PLANE POLARIZED LIGHT

By DR. W. G. WELLINGTON

Forest Insect Laboratory, Sault Ste. Marie, Ontario

IT has been suggested that the dorsal ocelli of adult insects are only stimulatory organs, capable of increasing any response to stimuli received through the compound eyes, but incapable of evoking a motor response by themselves[1,2]. Behaviour studies that support this view include those in which bees[3] or ants[4] acted as though blind when only their ocelli were uncovered, and those in which bees[5] and *Drosophila*[6] reacted more rapidly to sudden variations in light intensity when their ocelli, as well as their compound eyes, were uncovered.

Adult ocelli vary in complexity, and Wigglesworth[7] has pointed out that their function may not be the same in all insects. Adults of many species, however, have ocelli that are quite similar to the lateral ocelli of the larvæ of tenthredinid sawflies—insects that certainly exhibit motor responses to light. Consequently, it has never been completely clear why adult ocelli of this type should not evoke similar reflex movements quite independently of any evoked by the compound eyes.

At the low temperatures (20–23° C.) and low light intensities commonly used in laboratory tests of light reactions, larvæ of the *Neodiprion* sawflies orientate themselves much less precisely to a point source than they do to intensity gradients from the unobstructed sky outdoors. Even outdoors, however, they seldom maintain as steady directions of travel as lepidopterous larvæ that have several stemmata more widely distributed over the sides of the head. These facts suggest that the type of response evoked by adult ocelli might also be influenced by several factors. Therefore, it seemed worth while to test some adult insects outdoors as well as indoors, so that the effects of natural light from the sky could be observed.

The species used was *Sarcophaga aldrichi* Parker, a common dipterous parasite. At ordinary room temperatures, the fly is strongly photopositive, and either crawls or flies directly towards a light when released. Clipping the wings does not alter this response, so this was done to keep specimens from escaping during outdoor tests. Flies tested were always freshly collected outdoors, since it was found that they did not survive prolonged storage at room temperature, and that those stored at lower temperatures for more than a few hours could not withstand the high surface temperatures when they were taken outside again. Blackboard paint was used to cover the ocelli or the compound eyes. The surface of the paint was always checked for cracks after each test, to guard against discrepancies produced by exposure of a few ommatidia.

Fig. 1 shows examples of the types of tracks obtained. Tracks *A*–*E* show the responses to a 6-watt panel lamp resting on a table in a darkened room. Tracks *A′*–*E′* show the movements of the same individuals on cardboard on the ground outdoors. The lines on the tracks indicate 10-sec. intervals.

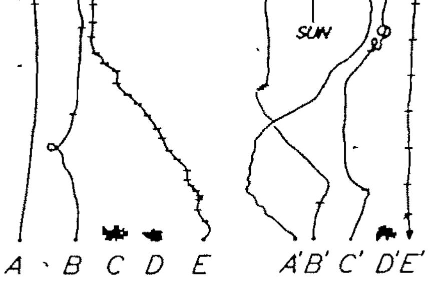

Fig. 1. Responses of *Sarcophaga* and a *Neodiprion* larva to light indoors and outdoors. Tracks *A*–*E*: movements in a darkened room with a 6-watt lamp in the position shown. *A*: a fly with all its eyes uncovered; *B*: a fly with only its compound eyes uncovered; *C*: a fly with only its ocelli uncovered; *D*: a fly with all its eyes covered; *E*: a fourth-instar larva of *Neodiprion sertifer* (Geoff.). Tracks *A′*–*E′*: movements of the same individuals over the ground outdoors. Time-marks on all tracks show 10-sec. intervals

In the indoor group, track *A* shows the path of a fly with all its eyes intact, whereas track *B* shows the movements of a fly with only its compound eyes functioning. In *B*, the slower response is evident. Track *C* shows the small amount of undirected movement that occurred when only the ocelli were uncovered, and track *D* shows the result of covering all the eyes. Track *E* shows the path of a fourth-instar larva of *Neodiprion sertifer* (Geoff.).

In the outdoor group, the tracks of moving insects showed some orientation with respect to the sun, the direction of which is indicated. The important difference between this and the former series is shown in *C′*, the path of the fly with only its ocelli uncovered. Clearly, the movements were as directed as any made by flies with more eyes functioning.

Track *D′*, the path of the fly with all its eyes painted, was still similar to *D*, indoors. Such a small amount of undirected movement outdoors occurs only when blind flies are not too hot. When they are overheated, they move more; but, in the absence of wind, their movements are still relatively undirected. When there is a gentle breeze, the blind flies can travel in relatively straight lines away from the sun.

The flies that made the tracks *A′*–*D′* were all cool, but the sawfly larva (*E′*) was tested later in the day, and was hot enough to move directly away from the sun[7]. The irregularities shown in tracks *A′*–*C′* were produced by responses to patches of cirrus cloud or smoke passing overhead, and do not occur when the sky is clear. The sawfly was tested when there was only haze, so that its track was straight, in striking contrast to *E*, indoors.

It has already been shown that larvæ of various species, including those of the sawfly, *N. banksianae* Roh., respond to rotation of the axis of a sheet of 'Polaroid' while they are crawling on the ground[7]. This is a similar response to that originally described by von Frisch in bees[8], and observed more recently in other types of adult insects[9], in mosquito larvæ[10], and in other arthropods[10,11]. Fig. 2 shows examples of responses of adults of *S. aldrichi* and of a larva of *N. sertifer* to 'Polaroid' rotation while the insects were travelling on the ground.

The circles and their accompanying pointers beside each track in Fig. 2 show the points at which a sheet of 'Polaroid' was placed over the moving insect, or rotated, or withdrawn. The bars within the circles indicate the orientation of the axis of the 'Polaroid' with respect to the sun, and the black circles indicate that the sky appeared appreciably darker when the axis was orientated as shown. It can be seen that maximum darkening usually occurred when the axis pointed towards the sun, not at right angles to it, and that orientation of the axis towards the sun generally resulted in a change in the direction of travel. The exception is discussed in sequence below.

Track *A* shows the path of a fly with all its eyes functioning. The first two turns in this track are examples of a relatively rare response that has been observed at least once in each species tested to date—a change in direction sometimes amounting to nearly 180° in response to a 90° rotation of the 'Polaroid' axis—but the sky conditions associated with it are still not fully understood. The remaining

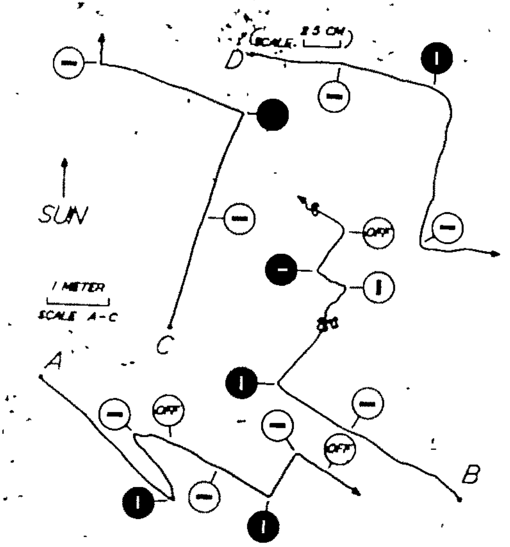

Fig. 2. Effects of rotation of the axis of a sheet of 'Polaroid' on the direction of travel of *Sarcophaga* and of a *Neodiprion* larva crawling over the ground. Circles show the points at which the sheet of 'Polaroid' was placed over a moving insect, or rotated, or withdrawn. The bars inside the circles show the orientation of the axis with respect to the sun, and the colour of the circle indicates whether or not the sky was appreciably darkened when viewed through the 'Polaroid' with the axis set as shown. Track *A*: a fly with all its eyes functional; *B*: a fly with only its compound eyes uncovered; *C*: a fly with only its ocelli uncovered; *D*: a fourth-instar larva of *Neodiprion sertifer* (Geoff.)

directional changes are of the type most often observed when the axis is turned through 90°, and are the expected responses to the axis directions shown. (Turns are often extremely sharp, within one to five body-lengths; but, occasionally, a smoother, slower turn is made that does not show well at reduced scale.)

Track *B* shows the path of a fly with only its compound eyes uncovered. The marked convolutions in the path about one metre after the first response to rotation occurred when a patch of cirrus passed overhead. Irregularities in the path continued to appear as additional wisps of cloud followed the first patch and, finally, at the point marked by the second white circle, a larger cirrus cloud produced a steady change in polarization, and the insect returned to its original heading. It maintained this heading until the axis was rotated to the position that had previously produced no response under a clear sky, but this time the response was obtained under the cloud. Such changes in the direction of travel associated with changes in polarization are common occurrences under smoke, cirrus and, occasionally, haze[7], and sometimes make it impossible to obtain reproducible results, especially near large industrial centres.

Track *C* shows the responses of a fly with only its ocelli functioning, and track *D*, on a different scale, shows the path of a fourth-instar larva of *N. sertifer*. It is clear that the ocelli of the adult sarcophagid are as sensitive to changes in the polarized light from the sky as are those of the sawfly larva.

The foregoing results show that the dorsal ocelli of adults of *S. aldrichi* are quite capable of evoking motor responses by themselves. Moreover, movements that flies with only ocelli make outdoors are just as directed as those made by flies that have all their eyes intact. In fact, only two really consistent differences were observed outdoors between flies with functional compound eyes and those with only ocelli. First, those with compound eyes were easily startled by movements of the observer, whereas those with only ocelli were indifferent to all but the most obvious and rapid changes in light intensity produced by these movements. Secondly, when clouds covered both the sun and the zenith, intact adults seldom stopped moving, whereas those with only ocelli invariably stopped until the sun reappeared; and, even then, they made only undirected movements until the overhead sky cleared again. In short, these flies behaved more like larvæ than like adults. [Aug. 5.

HEXAMITA MELEAGRIDIS

By D. SLAVIN and J. E. WILSON

Ministry of Agriculture and Fisheries Veterinary Laboratory, Lasswade, Midlothian

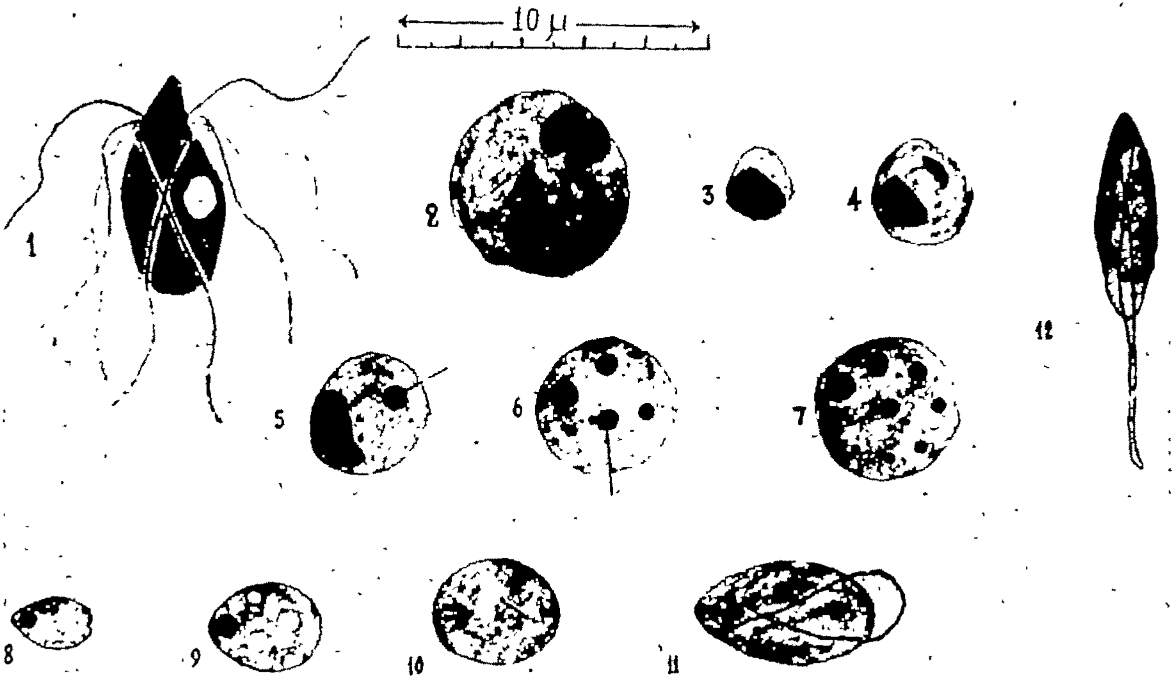
IT was shown by Hinshaw, McNeil and Kofoid[1] and by Hinshaw and McNeil[2] that a serious enteric disease of turkeys in the United States of America is caused by a protozoan parasite which they named *Hexamita meleagridis*. A description of its morphology was later given by these authors[3].

In the course of investigating several serious outbreaks of the disease in Great Britain, an extensive systematic study of the life-cycle of the causal parasite was made; our results differ in certain respects from those already reported. As they revealed some hitherto unrecorded information which may assist in a better understanding of the epidemiology of the disease, they are considered to be worth publishing.

Because of certain morphological resemblances to *Giardia* and *Hexamita muris*, *Hexamita meleagridis* has been assumed to reproduce by simple binary fission, one flagellate producing two, and so on. The present work has shown this to be erroneous, and has clearly demonstrated the reproductive cycle in the reticulo-endothelial cells and tissue interspaces of the bowel wall. The most heavily invaded sites are the villi of the small intestine, excepting those of the duodenum. After innumerable examinations of stained smears by standard microscopic means and of wet preparations by phase contrast, no dividing flagellates have ever been seen.

The life-cycle as found here is briefly as follows: the development of a binucleate cyst from the mature flagellate (Fig. 1), production of invasive forms from these cysts, probably by breaking free of the nuclear structures, invasion of reticulo-endothelial cells and tissue interspaces with formation of schizonts and merozoites, which finally develop into mature flagellates.

Cysts. The easiest method of demonstrating cysts was to wash out the bowel of heavily infected birds



Figs. (1) The mature flagellate. (2) A forty-eight-hour old cyst. (3 and 4) The earliest invasive forms seen 24 hr. after experimental infection. (5, 6 and 7) Various types of schizont; in each case the blue body has a line pointing to it. (8, 9 and 10) Development stages of the merozoite. (11) Early motile intracellular form of *Hexamita* as seen under phase contrast. (12) The tadpole form as seen under phase contrast

with 10 per cent serum broth, allow the gross matter to sediment, and concentrate the mature flagellates by centrifugation. The heavy suspension of flagellates was then incubated at 37° C., and within two hours a high proportion had encysted. Encystment under a sealed coverslip was also observed by phase contrast. The fully developed cyst (Fig. 2) is quite round, about 6·0 μ in diameter, and has a double nucleus to one side. Some of the flagella may be retained for days after encystment. The development of the invasive form from the cyst has not been completely traced, as not many of our experimentally infected birds were destroyed for examination within 24–48 hr. after exposure, but the earliest forms seen at 24 hr. are as in Fig. 3. They are about 1·5–2·0 μ in diameter, have very dense chromatin with acidophil cytoplasm and probably arise in twos by simple freeing of the nuclear structures of the cysts. Some of these early forms may show double chromatin structures (as in Fig. 4) or even treble ones, but the chromatin is always unevenly divided and always dense.

Schizogony cycle. The earliest schizont is a round pale pinkish-staining structure with a large dense chromatin body to one side and always a smaller round blue body at the other side, as in Fig. 5. The blue body may or may not have a number of small dense chromatin dots (up to eight have been counted in some), and appears to play an essential part in the division of the chromatin of the schizont. Sometimes, as in Fig. 6, a small chromatin dot is seen closely attached to the blue body, and it is not clear at present whether the chromatin structures of the schizonts are extruded by the blue body or whether the blue body simply initiates division of the chromatin already present in the schizont. The latter seems the more likely process, as in schizonts with only one chromatin mass this is always large and in schizonts with several chromatin bodies these are always smaller. Whatever the process involved, the final picture is as in Fig. 7. This shows a characteristic schizont with seven chromatin bodies (the highest number we have seen) and the central blue body. A constant feature of these schizonts is the inequality of division of the chromatin and its density, and the presence of the blue body.

The subsequent development of the flagellate from the schizont is not clear, but examinations so far indicate that the chromatin bodies break up into merozoites about 1·0 μ in length and similar to that shown in Fig. 8, as in sick birds killed before the appearance of flagellates in the intestine there have been noted groups of three to four small merozoites. One schizont has actually been photographed showing this break-up of a chromatin body, but it has not been illustrated here as there is still some doubt of the reproductive process at this stage. The development process in Figs. 8–12 and in Fig. 1 have been clearly traced. The merozoite in Fig. 8 is a little more than 2·0 μ long, with bluish homogeneous cytoplasm and a dense purple-staining round nucleus. As this enlarges, its cytoplasm stains more faintly and a few vacuoles develop as in Fig. 9. Then the nucleus breaks up and primitive development of the posterior flagellum commences as in Fig. 10. Further development is seen in Fig. 11. When parasites at this stage are examined under phase contrast, they appear to be in an envelope. They are sluggishly motile and progress by waving the tail membrane containing the primitive posterior flagellum and by sending undulations down the sides of the body. This indicates that they already possess primitive anterior flagella enclosed in a membrane or still within the body of the parasite although they have not been illustrated here. The next stage is the tadpole form (Fig. 12) and this precedes the mature

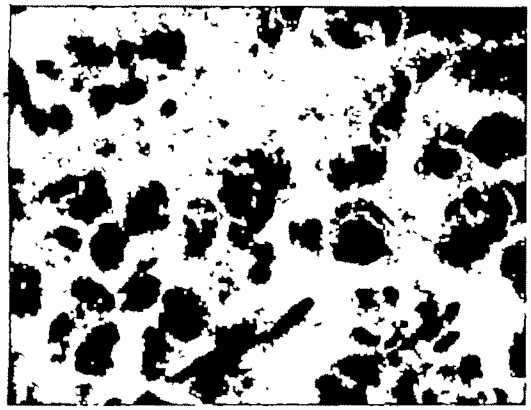


Fig. 13. Cross-section of a villus of small intestine, stained hæmatoxylin × 1,000. The upper portion of the photograph shows the epithelium of the villus. Beneath this is the basement membrane, and throughout the rest of the photograph can be seen reticulo-endothelial cells packed with development forms of the parasite, probably the stages of Figs. 9, 10 and 11

flagellate. It is about the same size as the mature flagellate and has a long streaming membrane enclosing the posterior flagellum. It is rather gracefully motile in contrast to the active zigzag movement of the mature flagellate and proceeds by waving the posterior membrane and sending undulations down the body. The anterior flagella are probably present at this stage also but enclosed within the body of the parasite or under a covering membrane. Both Figs. 11 and 12 were drawn from phase-contrast examination, and although this method shows up a good deal of internal structure, it has never been possible to see the anterior flagellum of the tadpole forms.

When the parasite has developed motile forms in the reticulo-endothelial cells of the villi, they make their way through the epithelium into the lumen of the bowel and immediately go down into the glands to feed and mature. In sections of bowel from heavily infected birds, the reticulo-endothelial cells of the villi are packed with developing forms of the parasite (Fig. 13), while the glands are packed with flagellates. These two factors suffice to make the disease a most difficult one to treat, as an effective therapeutic agent would have to destroy the developing forms of the parasite in the reticulo-endothelial cells of the villi or kill the mature parasites deep in the glands. Most of the established antiprotozoal drugs have been tried here on artificially infected poults, and none was found which effectively did either. Few had even any action *in vitro*, but liquid 'Entramin' killed within minutes. Birds given it in drinking water had a higher rate of survival than untreated birds, as a proportion of the parasites were killed when they entered the lumen of the bowel. The initial development of the parasite in a new host is directed towards establishment of a population, and when birds first show symptoms of illness the schizogony cycle is well advanced and the foundations laid for further severe progress of the disease. The therapeutic agent of choice would therefore be one which killed the developing forms in the bowel wall.

As it was not possible to watch the actual development of each form of the parasite into the succeeding one by tissue culture or by examination of material from birds killed at set intervals after artificial infection, some gaps in the life-cycle have had to be filled in deductively. These are the development of invasive forms from the cysts and of merozoites from the schizonts. However, it is felt that further study will prove the deductions made on these stages to be substantially correct.

Hexamitiasis is a deadly disease, and the main bulk of the present work was directed towards finding an effective curative agent; when once the salient points in the life-cycle had been uncovered, not many birds were slaughtered solely for more detailed study of the developmental stages.

A number of *Hexamita muris* from white rats was examined both under phase contrast and in stained smears. The morphology was found to be as stated by Wenyon[4]. Apart from some resemblance in shape and the possession of six anterior and two posterior flagella, there was nothing to indicate any relationship between this flagellate and *Hexamita meleagridis*, and the two will eventually have to be placed in separate genera.

'ADENOSINE TRIPHOSPHATE–CREATINE TRANSPHOSPHORYLASE' AS RELAXING FACTOR OF MUSCLE

By Dr. L. LORAND

Institute for Muscle Research, Marine Biological Laboratory, Woods Hole, Massachusetts

THE recently published work of Goodall and A. G. Szent-Györgyi[1] clearly showed that—apart from certain ionic requirements—there are at least two factors in muscle jointly concerned with relaxing the adenosine triphosphate-induced tension of glycerinated fibres. They discovered that one of these is phosphocreatine and the other was shown to be a heat-labile, non-dialysable component that could be obtained from muscle by extraction with 0·05 *M* sodium bicarbonate. This second principle, called *X*-factor, was presumed to be a protein (or several proteins), and it was also inferred that it may turn out to be an enzyme for which phosphocreatine is a substrate. The present communication reports the identification of this relaxing protein component of muscle, showing that it is 'adenosine triphosphate–creatine transphosphorylase', catalysing the reaction:

$$\text{phosphocreatine} + \text{ADP} \rightleftharpoons \text{creatine} + \text{ATP}.$$

Muscle fibres. For test material, bundles of muscle fibres were cut out from rabbit psoas and washed with 50 per cent (v/v) glycerol at 0° C. for 24 hr., according to A. Szent-Györgyi[2]. The fibres were then treated for five days at − 20° C. with 50 per cent (v/v) glycerol containing 0·05 *M* sodium bicarbonate. According to Goodall and A. G. Szent-Györgyi[1], this additional treatment washes out all relaxing factors from the fibres. Indeed, this was borne out by the control runs, an example of which is shown in Fig. 1. After treatment for five days, the fibres were stored in 50 per cent (v/v) glycerol at − 20° C.

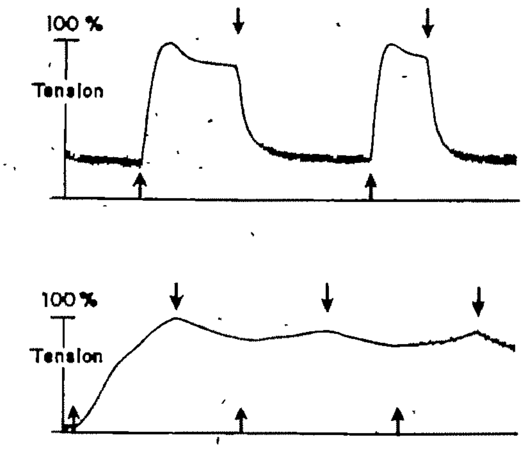

Fig 1. Upper curve: Effect of alternating the pH in the presence of muscle extract
Lower curve: The effect of alternating the pH in the absence of muscle extract. Adenosine triphosphate, phosphocreatine, magnesium ions, potassium ions present (control run)
↑ = fibre immersed in neutral bath; ↓ = fibre immersed in pH 6·2 bath

Testing the relaxing activity of muscle fractions. Procedures were identical with those described by Goodall and A. G. Szent-Györgyi[1], and the tests were carried out at room temperature. The fibres were incubated in the test solution for 15 min. prior to mounting in the isometric tension recorder designed by Goodall. Both baths, in which the fibre is immersed alternately, contain test fluid of identical composition: 0·3 ml. 0·05 *M* sodium adenosine triphosphate, 0·3 ml. 0·1 *M* sodium phosphocreatine, and 2·4 ml. of the muscle fraction to be tested dissolved in 0·1 *M* potassium chloride and 0·001 *M* magnesium chloride. Nitrogen is bubbled through one of the baths, thereby maintaining a pH around neutrality (pH 7·2), while carbon dioxide is passed through the other, establishing a somewhat more acidic pH (around pH 6·2). If foaming is excessive, a drop of capryl alcohol may be added. Tension develops when the fibre is immersed in the neutral bath. It can be seen in Fig. 1 that tension develops much faster in the system where muscle extract is present, together with adenosine triphosphate and phosphocreatine, than in the control where only the two latter substances are available. This clearly indicates that muscle contains a factor that accelerates the development of tension. The same observation was made earlier by Goodall and A. G. Szent-Györgyi[1], who also found that as regards the speed of attaining full tension the addition of a small amount of a neutral solution of cysteine has the same effect as muscle extract.

Full tension will persist as long as the fibre is kept in the neutral medium; but as soon as the bath is changed for the more acidic one, the tension falls abruptly if the relaxing factor is present. In the absence of this factor, acidification results only in a slow and small drop in tension, as shown in Fig. 1.

By placing the glycerinated fibre, in the presence of magnesium ions, potassium ions, adenosine triphosphate, phosphocreatine and the relaxing factor, alternately in the neutral and the acidic bath, the fibre can be carried through cycles of tension and relaxation as many times as the pH is changed. The pH dependence of tension in this system served as a useful assay in isolating the relaxing factor. The percentage drop in tension when the fibre is placed in the bath of lower pH may be taken as a quantitativ sign of the relaxing activity of the medium. Th quantitative evaluation of relaxing activity in th rigorous sense may be somewhat uncertain, becaus it is difficult to know for certain that the penetratio of the relaxing factor into the fibre and its distribution within is complete and uniform all the tim In spite of these uncertainties, if a physico-chemicall homogeneous substance could be isolated that woul cause relaxation when applied in small concentrations, it would be highly probable that the isolate material was identical with the relaxing factor.

Isolation and characterisation of the relaxing facto Since its outset, it has been the purpose of this work to decide whether enzymes that phosphorylat adenosine diphosphate would act as relaxing factor Therefore, initial fractionation of the muscle extrac was so directed that isolation steps were included from Banga's description[3] for preparing 'adenosine triphosphate–creatine phosphopherase'. Enzyme activity was determined by the procedure used by Banga this consists of measuring phosphocreatine (as 'easily hydrolysable' phosphate by the method of Fiske an SubbaRow[4]) produced in the presence of the enzym from adenosine triphosphate and creatine. It wa found that preparations active as enzymes woul also cause relaxation of the glycerinated fibre. A this point it was of utmost help that a newly devised method was made available by Kuby Noda and Lardy[5] for purifying 'adenosine triphosphate-creatine transphosphorylase'. This purificatio results in an enzyme preparation that is homogeneou in the ultracentrifuge and the electrophoresis apparatus. I am greatly indebted to Dr. H. A. Lard for hitherto unpublished details of the method o enzyme isolation that run briefly as follows[5].

"Rabbit skeletal muscle is extracted with 0·01 *M* potassium chloride and the extract is fractionated in the following steps: (1) Heat denaturation o inert proteins at 40° C. (2) Fractionation at − 10° C in the presence of 0·1 *M* magnesium acetate at pH 6·5, between 52 and 67 per cent (v/v) of 95 per cent ethanol. (3) Denaturation of inert proteins at 20° C., pH 8·5, 60 per cent (v/v) of 95 per cent ethanol, and precipitation of the protein magnesium salts at 20° C. in 60 per cent (v/v) of 95 per cent ethanol, 0·03 *M* magnesium sulphate at pH 8·5, followed by fractional extraction with 0·07 *M* magnesium sulphate, pH 9·0 at 0° C. (4) Fractionation at 0° C. in the presence of 0·1 *M* manganese acetate, pH 6·8, between 56·6 and 65 per cent (v/v) of 95 per cent ethanol. (5) Precipitation of the enzyme at 0° C. in 0·02 *M* sodium chloride, 0·005 *M* zinc acetate, pH 7·0, 34 per cent (v/v) of 95 per cent ethanol."

During the course of the isolation of the enzyme, the various fractions were tested for relaxing activity, thereby obtaining an estimate of the yield and degree of purification of the relaxing factor. A typical example may be cited. It was found that the supernatant of fraction 1 caused a 60 per cent drop of tension. Fraction 2 did the same when made up to the volume of the supernatant of fraction 1. Also, a 60 per cent drop of tension was obtained with fraction 4 when made up to about two-thirds, and with fraction 5 when made up to about half the volume of the supernatant of fraction 1. This implies that about 50–60 per cent of the total relaxing activity present in the supernatant of fraction 1 can be recovered in the final fraction. At the same time, the total protein content of the supernatant of fraction 1 was found to be 36–50 times greater than that of fraction 5. Thus, from the point of view of relaxing activity, a purification of 18–30 fold has been achieved between fractions 1 and 5. Since the yield and degree of purification of 'adenosine triphosphate–creatine transphosphorylase' obtained by the procedure is of the same order of magnitude[5], it is obvious that the purification of the enzyme results in a similar purification of the relaxing factor.

To corroborate the suggestion that the enzyme and relaxing factor may be the same substance, a final check was made using an enzyme preparation of Drs. S. A. Kuby and L. Noda and kindly given to us by Dr. H. A. Lardy. The assays of these workers showed that the preparation had the highest activity obtainable for 'adenosine triphosphate–creatine transphosphorylase', and the preparation was homogeneous by electrophoresis under a wide variety of experimental conditions, in the ultracentrifuge and also by solubility tests. This enzyme preparation was highly potent when tested for relaxing activity, and Fig. 2 shows an example of its effect when used in a concentration of about 0·3 mgm./ml.

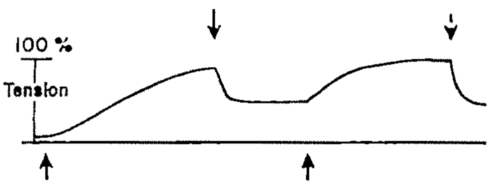

Fig. 2. Tension-relaxation cycles of glycerinated fibre in the presence of magnesium ions, potassium ions, adenosine triphosphate, phosphocreatine and pure 'adenosine triphosphate–creatine transphosphorylase'
↑ = fibre immersed in neutral bath; ↓ = fibre immersed in pH 6·2 bath

Discussion. It has been shown that glycerinated fibres (representing the contractile element of muscle) can be carried through full activity cycles of tension and relaxation when immersed in a solution composed of pure substances. Since all constituents of the medium are used in physiological concentrations, it would appear that the development of tension and subsequent relaxation proceeds also in living muscle by the same mechanism. When glycerinated fibres are in a solution containing potassium ions, magnesium ions, adenosine triphosphate, phosphocreatine and pure 'adenosine triphosphate–creatine transphosphorylase', alteration in the *p*H from about *p*H 7·0 to about *p*H 6·0 can initiate the activity cycle: neutral *p*H favours contraction, and the lower *p*H relaxation. It has been shown[6] that such *p*H changes can occur in the intact muscle fibre. Moreover, according to Dubuisson[7], relaxation is associated with an increase in *p*H, which again points to the possibility that an alternating change of *p*H inside the muscle fibre may be the actual 'trigger' for initiating contraction and relaxation. The recent work of Bozler[8] and Goodall and A. G. Szent-Gyorgyi[1] showed that small amounts of calcium ions may have an equally important part in initiating the activity cycle: the presence of calcium ions favours contraction, their absence enhances relaxation. In the living muscle, *p*H and concentration of calcium ions may turn out to be independent or complementary parameters in controlling the activity cycle.

'Adenosine triphosphate–creatine transphosphorylase' has been suspected by several workers to be involved in the relaxation of muscle; the present work is the first definite proof to that effect. It has been shown that phosphocreatine facilitates relaxation only in association with the enzyme. Thus it seems that relaxation means rephosphorylation of adenosine diphosphate bound to the contractile proteins. In such a picture, the state of muscle when contraction is initiated would correspond to $\text{ATP}\cdot_{\text{AM}}$ ('AM' index signifies that the nucleotide is bound to actomyosin) and to $\text{ADP}\cdot_{\text{AM}}$ when contraction is complete. If during contraction the protein-bound adenosine triphosphate is dephosphorylated, relaxation can be described as follows:

$$\text{Phosphocreatine} + \text{ADP}\cdot_{\text{AM}} \xrightarrow{\text{transphosphorylase}} \text{creatine} + \text{ATP}\cdot_{\text{AM}}.$$

Future experiments may show that systems that can produce adenosine triphosphate (such as the phosphocreatine plus 'adenosine triphosphate–creatine transphosphorylase' system) have an effect on purified actomyosin similar to that on the relaxation of the glycerinated fibre. In this connexion, it is interesting to recall some experiments of Laki (personal communication). He noticed an apparent volume increase of the myosin *B* 'superprecipitate' in the presence of creatine, magnesium ions and dialysed muscle extract. (It is conceivable that appreciable amounts of phosphocreatine were formed in this system that were responsible for the observed effect.)

The relaxation of muscle fibre being equivalent to rephosphorylating the adenosine diphosphate bound to the proteins, it is to be expected that, besides 'adenosine triphosphate–creatine transphosphorylase', other enzymes, too, that can produce adenosine triphosphate from the diphosphate, would facilitate the relaxation of the muscle fibre. Such a potentially active substance would be myokinase, which produces adenosine triphosphate by dismutation of two adenosine diphosphate molecules. One would expect, however, such systems to work more slowly in producing relaxation, and therefore they would only be of secondary importance from the physiological point of view as compared with the phosphocreatine and 'adenosine triphosphate–creatine transphosphorylase' system. The relaxing factor described by Marsh[9] has recently been proved to be a protein[10]; when isolated, it may turn out to be identical with the transphosphorylase discussed in the present work, or it may be another enzyme producing adenosine triphosphate, such as, for example, myokinase.

I wish to thank Mr. M. C. Goodall and Dr. Andrew G. Szent-Györgyi for their help and Mr. P. Neal for his enthusiastic work. My thanks are also due to Prof. Albert Szent-Gyorgyi for the benefit of discussions.

The work described in this article was carried out while on leave of absence from the Department of Physiology and Pharmacology, College of Medicine, Wayne University, Detroit, Michigan. It was aided by grants from Armour and Co., Chicago, the American Heart Association, the Association for the Aid of Crippled Children, and the Muscular Distrophy Association.

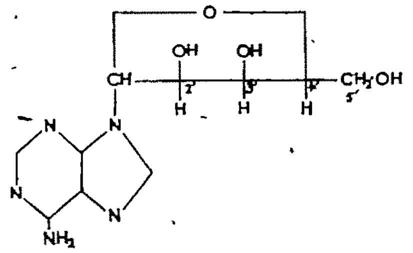
Structure of Adenylic Acids *a* and *b*

With the demonstration[1] that the main internucleotidic linkage in ribonucleic acids is *b* : 5′, it is clear that a final decision between 2′ : 5′ and 3′ : 5′ as possible linkage positions[2] can be reached by determining the location of the phosphoryl group in the isomeric *a* and *b* nucleotides obtained by alkaline hydrolysis of ribonucleic acids[3]. Brown and Todd[4] showed that these nucleotides are the 2′- and 3′-phosphates of the corresponding nucleosides, although not necessarily respectively.

Indirect evidence[5] of a physical nature has been advanced for the view that cytidylic acid *b* is cytidine-3′-phosphate; this evidence, which would also indicate[6] that uridylic acid *b* is uridine-3′-phosphate, is plausible but scarcely decisive. More direct evidence[7] has been provided in the case of the isomeric adenylic acids; hydrolysis of the isomers with an acid ion-exchange resin followed by study of the mixture of phosphorylated ribose derivatives so obtained indicated with some probability that the adenylic acids *a* and *b* were respectively the 2′- and 3′-phosphates of adenosine (I). This conclusion, although probably warranted, suffers from the defect that it rests on arguments concerning the relative speeds of phosphoryl migration and hydrolysis during contact with the ion-exchange resin used. The problem of providing rigid and unambiguous proof of structure thus remains, and we have attacked it in the case of the isomeric adenylic acids using both chemical and physical methods.

The difficulty which besets any chemical method of structural determination is the ease with which phosphoryl migration occurs in the *a* and *b* nucleotides; the free acids undergo migration in acid, although not in alkaline, media, while their esters are labile both under acid and alkaline conditions[3,4]. Clearly no chemical proof of structure can be valid if it involves group migration at any stage. Thus the application of the classical methylation procedure employed for structural determination in the carbohydrate series is of no value, since phosphoryl migration occurs during methylation[8]. We were able to surmount the difficulty in the following way.

Partial acetylation of 5′-acetyladenosine yielded only one 0 : 0-diacetyladenosine. Treatment of this diacetyl derivative with 0-benzyl phosphorus 0 : 0-diphenyl phosphoric anhydride followed by phosphite–phosphate interconversion[9] yielded a diacetyladenosine benzyl phosphate from which the benzyl group was removed by catalytic hydrogenation.



(I)

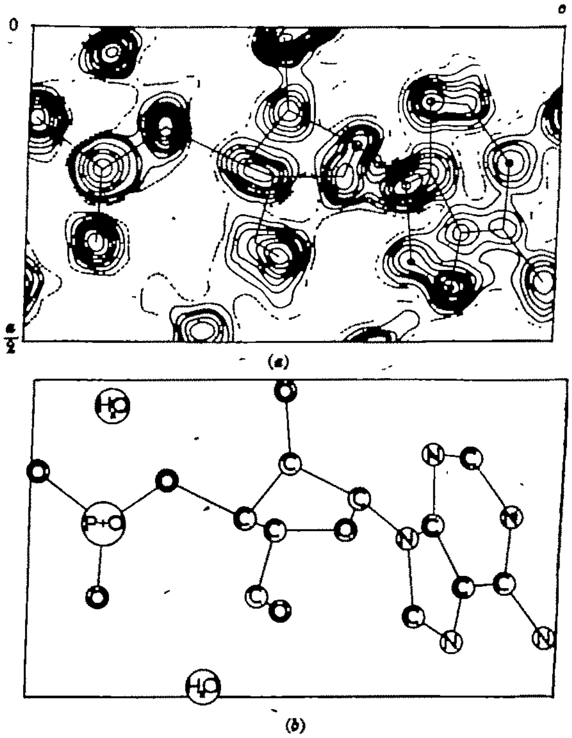


Fig. 1. Calculated electron density for adenylic acid *b* projected on (010). Contours at 1e.A.$^{-1}$ interval with dashed contour 2e.A.$^{-1}$. The dotted contours around the overlapped phosphorus and oxygen are at 5, 10, 15, 20 and 25 e.A.$^{-1}$

Gentle alkaline hydrolysis of the diacetyladenosine phosphate prepared in this way removed the acetyl groups and yielded adenylic acid *a* alone and uncontaminated by any of the *b* isomer. Since *only* the *a* isomer was obtained, it is clear that no phosphoryl migration could have occurred at any stage and hence the diacetyladenosine used must have been *b* : 5′-diacetyladenosine. The *b* : 5′-diacetyladenosine was now treated with toluene-*p*-sulphonyl chloride, yielding *b* : 5′-diacetyl-*a*-tosyladenosine. Methanolysis of this product under conditions which do not cause migration of the tosyl group gave adenine and a methyl tosyl-D-ribofuranoside. The latter was separated, methylated and hydrolysed; the sole dimethylribofuranose obtained in this way was identified as 3 : 5-dimethylribofuranose. It follows that the original tosylated diacetyladenosine was 3′ : 5′-diacetyl-2′-tosyladenosine, and hence that adenylic acid *a* is adenosine-2′-phosphate.

Parallel with these studies we have also made a direct determination of the structure of adenylic acid *b* by X-ray crystallographic methods. This nucleotide crystallizes as colourless needles with an estimated 1·5 molecules of water for each molecule of acid[4]. Oscillation and Weissenberg photographs gave the unit cell data as:

$a = 10{\cdot}06$ A.; $b = 6{\cdot}30$ A.; $c = 11{\cdot}84$ A.; $\beta = 92{\cdot}5°$ and space group $P2_1$.

Intensities of the X-ray reflexions were visually estimated for the ($h0l$) zone and the projection of the structure on (010) was determined. Figs. 1*a* and 1*b* show a Fourier synthesis of the electron density on this plane and the appearance of the projected molecule. This clearly shows the position of the phosphate residue and establishes the *b* acid as the 3′-phosphate.

The investigation is being continued for the purpose f finding the stereochemistry of the molecule, bond-engths and angles, disposition of hydrogen bonds, tc., in more detail, and when this has been done a ull description of the structure and the method of tructure analysis employed will be published by one f us (M. M. W.).

Conversion of δ-Aminolævulinic Acid to Porphobilinogen in a Tissue System

We showed recently[1] that porphobilinogen is a highly specific precursor of porphyrins, and Shemin and Russell[2] have presented evidence that δ-aminolævulinic acid is a specific precursor of hæm. Shemin and Russell's finding has been confirmed independently in our system (cf. Neuberger and Scott[3]) to the extent that, on incubation with a chicken red cell hæmolysate[4], δ-aminolævulinic acid is converted to uro-, copro- and protoporphyrins. The yield of each of these porphyrins from δ-aminolævulinic acid was, moreover, identical to that[1] from an equivalent amount of porphobilinogen. The structure of porphobilinogen[5] suggests that this compound could be formed by the condensation of two molecules of δ-aminolævulinic acid (see also refs. 2 and 3), and the equivalence of the two compounds with respect to porphyrin formation may be taken as support for this idea. We now present evidence indicating the occurrence of such a condensation in the chicken red cell hæmolysate.

When δ-aminolævulinic acid is incubated with the hæmolysate, a substance reacting positively with Ehrlich's reagent can be shown to accumulate. After paper chromatography of this material in either a butanol – acetic acid or a phenol – ammonia solvent system[6], only one spot reacting with Ehrlich's reagent was found. With both solvent systems the R_F values and appearance of the spots were identical to those obtained with a crystalline sample of porphobilinogen hydrochloride. The material was concentrated[5]; on heating the resulting solution in acid[5], a porphyrin was obtained which, on paper chromatograms, behaved identically to the uroporphyrin obtained in the same way from pure porphobilinogen[5]. Furthermore, conversion to substances behaving on paper chromatograms as the acetyl and lactam derivatives[5] of porphobilinogen was demonstrated. We therefore believe that the material formed from δ-aminolævulinic acid in the hæmolysate is, in fact, porphobilinogen.

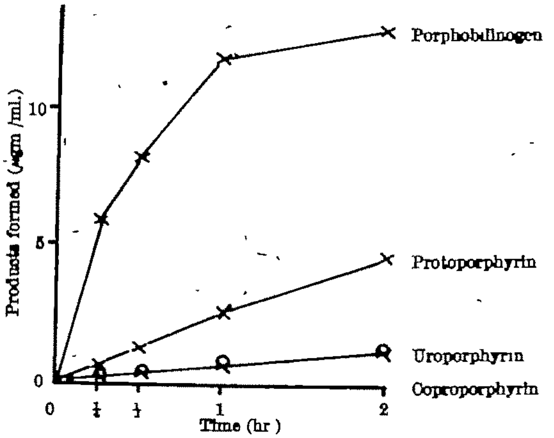

Fig. 1. Conversion of δ-aminolævulinic acid to porphobilinogen and porphyrins. Hæmolysate (ref. 4) incubated at 38°, with shaking in air. δ-Aminolævulinic acid added, 47 μgm./ml.

The accumulation of porphobilinogen, uro-, copro- and protoporphyrins in a hæmolysate incubated with δ-aminolævulinic acid is illustrated in Fig. 1. No trace of these substances was formed if the hæmolysate was boiled prior to the addition of δ-aminolævulinic acid.

We are continuing our study of the interconversions of the porphyrins and their precursors, and, in particular, the relation of these processes to the biosynthesis of hæm.

We thank Mr. J. J. Scott and Dr. A. Neuberger for a gift of δ-aminolævulinic acid, Miss A. Benson for her assistance and Prof. C. Rimington for his continuing support.

Chromatographic Behaviour of Intermedin as determined by *In vitro* Assays

Paper chromatography was used in a recent attempt to obtain purified intermedin, the melanophorotropic hormone of the pituitary intermediate lobe. This communication is submitted because of the new assays employed and the interesting chromatographic behaviour of intermedin activity.

Powdered hog posterior pituitary glands were treated by the method of Landgrebe, Reid and

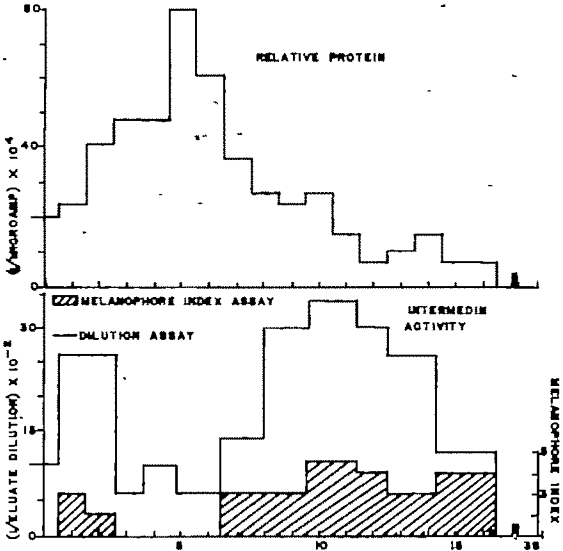

Fig. 1. Intermedin activity and protein concentrations on paper chromatogram

Waring[1] for the preparation of potentiated intermedin. The precipitate obtained was dissolved in distilled water and the resulting solution was applied in a series of adjacent 5-µl. drops forming a horizontal band near the bottom of a sheet of Whatman No. 1 filter paper. The band was built up by superimposed drops until 17·5 mgm. of pituitary material had been deposited. The chromatogram was developed in ascending fashion at room temperature with solvents consisting of the upper layer of a mixture by volume of 4 parts water, 4 parts *n*-butanol and 1 part acetic acid.

When the solvent front had ascended 38 cm. from the line along which the pituitary material had been applied, the chromatogram was dried, and 1·0-cm. wide vertical strips from each side were sprayed with ammoniacal silver nitrate and 0·2 per cent ninhydrin in water-saturated butanol. No reducing carbohydrates were detected. After the ninhydrin-positive areas had developed for several days, the strips were moved 1·0 mm. at a time past a 1·0-cm.^{2} opening in black paper masking the surface of a General Electric barrier-layer photo cell which was connected to a microammeter, and upon which was focused a microscope lamp. By plotting vertical distance up the chromatogram against reciprocal of ammeter reading minus reciprocal of ammeter reading when filter paper with nothing adsorbed to it was held over the photo cell, a crude estimate of the relative amounts of ninhydrin-positive material as a function of chromatogram height was obtained.

The chromatogram was cut into a series of horizontal strips and the adsorbed material from each strip was eluted in 1·0 ml. of distilled water per mm. of chromatogram height.

Eluates were assayed for intermedin activity by their effect on melanophores in the excised web of the foot of *Rana pipiens*. Webs were washed in amphibian Ringer solution until all melanophores were punctate, and cut into squares with areas of 1·0 mm.^{2} or less which were placed in depression slides. The measure of eluate activity was the reciprocal of the maximum dilution in millilitres of eluate per millilitre of Ringer which caused the melanophores to attain a stellate stage of pigment dispersion in 1 hr. Mixtures of eluates gave values that were averages of individual values.

Another assay technique depended on the observation that rate of pigment concentration after removal of intermedin was inversely proportional to the hormone concentration to which the melanophores were exposed. Web squares were immersed in 0·002 ml. of eluate per ml. of Ringer for 2 hr., at which time all melanophores were reticulate. The squares were then transferred to Ringer solution which was changed every 20 min. Two hours after transfer to Ringer solution, melanophore indices[2] of the web melanophores were noted.

Fig. 1 shows that intermedin activity exists in two concentration peaks: one associated with a small ninhydrin-positive peak with an R_F value of 0·28, the other with a ninhydrin-positive area with an R_F value of 0·04. The question of whether intermedin activity exists in two different molecules or in a molecule which adsorbs to different substances was not investigated.

The investigation of which this procedure was a part was undertaken during tenure of a National Science Foundation Fellowship.

The Fries Reaction

IN continuation of the study of the mechanism of the Fries reaction[1], a systematic investigation of the effect of medium on the rearrangement of phenyl (I; R=H)- and *p*-cresyl(I; R=CH_3)-hydrogen succinate in presence of anhydrous aluminium chloride has been carried out. The reaction was accomplished under standardized conditions using a constant temperature (117°, boiling *n*-butyl alcohol bath) for 2½ hr., the same molecular proportion of the ester (0·033 mole), aluminium chloride (0·067 mole) and the solvent (0·462 mole). The results are summarized in Table 1.

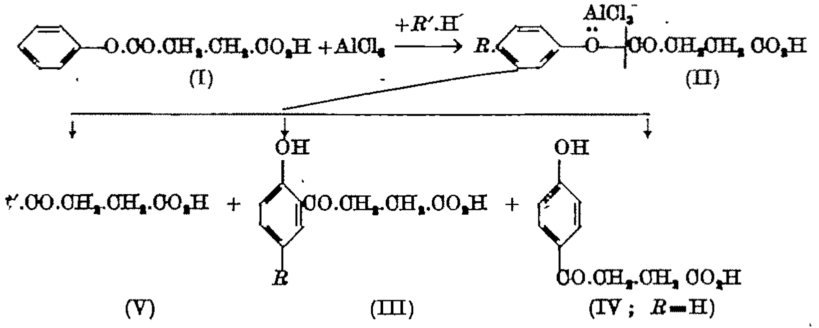
The results showed that, whereas phenyl hydrogen succinate, when heated with aluminium chloride in acetylene tetrachloride or nitrobenzene, gave a mixture of III (R=H) and IV, *p*-cresyl hydrogen succinate gave only III (R=CH_3)[2]. The structure of the latter acid (III; R=CH_3) was inferred from the fact that it was not etherified by diazomethane in absence of methyl alcohol[3], and that it gives a violet colour with ferric chloride[3,4]. When the reaction was carried out in a solvent the molecules of which contain *o*-, *p*-directing groups (that is, they are susceptible to the attack of electrophilic reagents) such as toluene, *m*-xylene, anisole, diphenyl ether and chlorobenzene, the oxo-carbonium ions[1], $\overset{+}{C}O.CH_2.CH_2.COOH$, combine with the solvent to give a non-phenolic β-aroyl propionic acid (V). The method adopted for the separation of the acids III, IV (as its ethyl ester), and V was based on esterifying the mixture with ethyl alcohol and hydrogen chloride, then extracting III and IV with sodium hydroxide solution. III (R=H) and IV were separated by diazomethane[1].

Table 1

Solvent	μ	I; $R = H$ (6·58 gm.)				I; $R = CH_3$ (7 gm.)	
		Mix. of III ($R = H$) + IV*	III ($R = H$)†	IV†	V†	III ($R = CH_3$)†	V†
Acetylene tetrachloride	0	5·3 gm.	3·8 gm.	trace	—	4·6 gm.	—
Nitrobenzene	4·96	3·2	0·63	0·38	—	3·9‡	—
Toluene	0·37	1·7	1·55	trace	0·9	1·27	1·11
m-Xylene	0·4	1·0	0·76	trace	3·1	0·30‡	2·68
Anisole§	1·2	—	—	—	1·98	—	2·25
Diphenyl ether	1·17	0·5	0·25	trace	5·16	—	3·80
Chlorobenzene	1·54	2·8	2·70	trace	0·55	2·65	0·63

* Crude. † Crystallised once and identified by melting point and mixed melting point with authentic specimens. ‡ Weight of the crude oduct, which was crystallized several times for purification. § Results not reliable since anisole was demethylated with aluminium chloride

The results showed also that, in the reaction with henyl hydrogen succinate, the ratio of the *p*-hydroxy-id (IV) increased with the increase in the dipole oment of the solvent[3] (cf. acetylene tetrachloride d nitrobenzene, Table 1).



$R = H$ or CH_3; $R' = p{-}CH_3.C_6H_4{-}$, $2:4(CH_3)_2.C_6H_3{-}$, $p{-}CH_3O.C_6H_4{-}$, $p{-}Cl.C_6H_4{-}$, or $p{-}C_6H_5.O.C_6H_4{-}$

The yields of the β-aroyl propionic acids (V) ncreased by the increase in the nucleophilic charcter of the solvent[6], and it was least in the case of hlorobenzene. This supports the previous assumption y Baddar and El-Assal[1] that the formation of IV nd V takes place by an electrophilic attack of the on $\overset{+}{C}O.CH_2.CH_2.CO_2H$ on the phenoxide – aluminium hloride complex and the solvent molecules, respectively[7].

It appears, therefore, that the ratio of *ortho* to *ara* in the Fries reaction, using aluminium chloride, lepends upon the nature of the ester and the ease of formation of the oxo-carbonium ion, on the dielectic constant of the solvent, and on the temperature of the reaction[8].

The investigation is being extended to *o*-, *m*-cresyl- and naphthyl-hydrogen succinates.

Thiamine Triphosphate in Bakers' Yeast

IN earlier work on cocarboxylase (thiamine diphosphate) as a phosphate carrier, an unknown spot was often found, not reported in the previous publication[1], when extracts from liver were chromatographed in order to isolate thiamine diphosphate from other phosphate compounds. This unknown spot gave, like thiamine diphosphate, a blue fluorescence in ultra-violet light after having been oxidized with potassium ferricyanide in alkaline solution. It also, like thiamine diphosphate, had biological activity when tested in a Warburg apparatus with washed yeast. In 1949 Velluz *et al.*[2] reported their work on synthetic thiamine phosphate, thiamine triphosphate, and its relation to thiamine diphosphate. When comparing this compound on a chromatogram with the unknown compound referred to above, I found them to behave in exactly the same manner. At the same time Rossi-Fanelli *et al.*[3] confirmed the occurrence of thiamine triphosphate in rat liver.

To be able, however, to study the mutual relations between thiamine tri- and diphosphate, and especially the synthesis of the two compounds from thiamine, I needed a system in which thiamine could be phosphorylated in greater amounts than in liver. According to Sperber and Renvall[4], bakers' yeast possesses the capacity of phosphorylating added thiamine to a rather large extent in the presence of glucose. Taking advantage of this, I obtained a yeast extract rich in thiamine phosphates. After a crude purification, the thiamine phosphates and remaining thiamine were chromatographed according to the method of Kiessling and Lindahl[5]. The results are shown in Fig. 1.

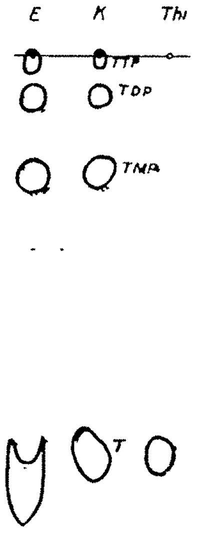

Fig. 1. *E*. Chromatogram of an extract from bakers' yeast in which thiamine has been partially phosphorylated *K*. Chromatogram of a mixture of thiamine and synthetic thiamine phosphates. *Thi*. Chromatogram of a thiamine solution. (*TTP* = thiamine triphosphate; *TDP* = thiamine diphosphate; *TMP* = thiamine monophosphate; *T* = thiamine)

The compounds are recognized as blue spots in ultra-violet light after being sprayed with a mixture of potassium ferricyanide and sodium hydroxide in alcoholic solution.

The different shape of the thiamine spot *T* in chromatograms *E* and *K* is due to the high concentration of added thiamine in the yeast extract after the phosphorylation process has been stopped.

The chromatograms give evidence of a marked ability of bakers' yeast to synthesize not only thiamine diphosphate but also thiamine triphosphate from thiamine.

A full description of this investigation will be published later in connexion with a comprehensive work on the synthesis and occurrence of thiamine phosphates.

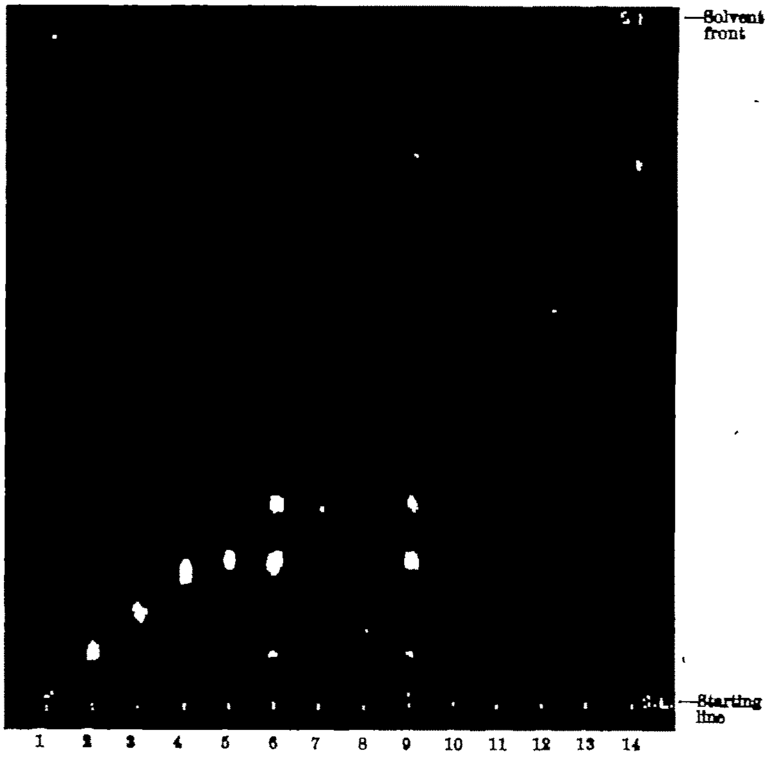
Isolation of *l*-Quinic Acid from the Peach Fruit

Malic and citric acids had been the only acids found in quantity in peaches[1], but Peynaud[2] showed that they accounted for only 40–80 per cent of the total acidity. Hulme and Swain[3], using paper chromatography, found that the pulp of the peach fruit contained an acid which had the same R_F value as an unknown acid in apples, later shown to be *l*-quinic acid[4]. Using displacement chromatography on an anion-exchange resin, pure *l*-quinic acid has now been isolated from ripe peaches, in which it is sometimes the major acid.

A set of columns of decreasing diameter[5] was packed with the strong-base anion-exchanger, 'Amberlite *IRA*-400'. Using three columns, mixtures of known acids were resolved by displacement with 0·1 *N* hydrochloric acid. The acids emerged in the following sequence: acetic, quinic, galacturonic, succinic, α-hydroxyglutaric, malic, tartaric, citric, malonic, α-ketoglutaric, oxalic and hydrochloric. The separation was sharp, except for the contamination of oxalic acid with hydrochloric acid. Similar results were obtained with columns of 4 per cent cross-linked 'Dowex 1', using either the hydroxide or the acetate form, even with three columns containing 3, 1 and 0·3 gm. of resin respectively.

Starting with an 80 per cent alcoholic extract, an aqueous solution was prepared which contained the water-soluble constituents from approximately 2 kgm. of ripe peaches. The bases and amino-acids were removed with a cation-exchanger and the acids were collected on a column of the weak-base anion exchanger 'Amberlite *IR*-4*B*'. This column was washed to remove sugars, and the acids were eluted with 2 *N* ammonia. The solution of peach acids was freed from ammonia and carbon dioxide, and run on to a set of five columns of 'Amberlite *IRA*-400'. The acids were displaced with 0·1 *N* hydrochloric acid, and the effluent was collected as 300 fractions of equal volume. Since the acids emerged in 0·1 molar solution, the molar proportion of each acid in the mixture could be estimated from the number of fractions collected. This calculation was confirmed by titration. The acids were identified by means of paper chromatography in two solvents and by the sequence of emergence from the columns, which was as follows: *l*-quinic, galacturonic, a mixture of minor acids including succinic, *l*-malic, citric and phosphoric, followed by the hydrochloric acid front. Successive acids overlapped by not more than three fractions. *l*-Quinic, *l*-malic and citric acids crystallized readily when the appropriate fractions were concentrated. One recrystallization from water gave pure *l*-quinic acid as colourless prisms of melting point 168° (literature[6] 162°) with $[\alpha]^{20}_{D} = -44°$ (literature[6] $[\alpha]^{18}_{D} = -44°$). The galacturonic acid was converted to mucic acid, and the phosphoric acid fractions gave the ammonium molybdate test. Eventually the acids from approximately 200 gm. of peaches were run on to three small columns and about thirty fractions were collected. The minor acids, including galacturonic acid, occupied two fractions and the other acids overlapped in one or two fractions.



Descending paper-chromatogram on No. 1 Whatman paper, run 18 hr. in methyl ethyl ketone – cineole – formic acid – water (50 : 50 : 20 : 16 v/v), sprayed with glucose and ammoniacal silver nitrate, fixed with thiosulphate. Acids: (1) galacturonic, (2) quinic, (3) tartaric, (4) phosphoric, (5) citric, (6) peach acids, (7) malic, (8) glycollic, (9) mixture of (1), (2), (5), (7), (8), (11) and (14), (10) α-ketoglutaric, (11) malonic, (12) succinic, (13) itaconic, (14) fumaric. *S.F.*, Solvent front; *S.L.*, starting line

Table 1. Peach Acids (moles per cent)

	Blackburn Elberta from Wedderburn, N.S.W.			J. H. Hale from Bathurst, N.S.W., 1950	Golden Queen from Leeton, N.S.W., 1950
	1950	1951	1952		
Quinic	28	40	38	18	16
Malic	40	30	20	47	64
Citric	25	22	36	28	12
Phosphoric	5	4	5½*	5	5
Others	2	4*		2	3

* Includes significant amounts of galacturonic acid.

The acids from three varieties of peaches grown in different locations, and from Blackburn Elberta peaches taken from the same orchard in three successive years, were separated as described. There was a considerable proportion of quinic acid in all the samples, and it was the major acid in one sample of Blackburn Elberta (see Table 1). All the peaches used were eating-ripe; some samples of less mature peaches will be tested next summer.

The two solvent mixtures mainly used for paper chromatography were alcohol – ammonia – water[7] and methyl ethyl ketone – cineole – formic acid – water (50 : 50 : 20 : 16 v/v). Cineole was used to hasten the removal of formic acid[8], and methyl ethyl ketone, in place of an alcohol, to avoid the difficulties caused by esterification. The separation of the acids (see photograph) was as good as that obtained with other solvent mixtures. A similar mixture containing mesityl oxide[9] gave very low R_F values. A permanent record of the acid spots was obtained by spraying with glucose and silver nitrate[10], and then fixing the paper with 1 per cent sodium thiosulphate.

Seasonal Variation in the Regeneration of Root-Cuttings

The recent publication of Hudson[1] recording an annual fluctuation of regenerating capacity in raspberry root-cuttings is paralleled by a number of observations on root-cuttings of horse-radish (*Armoracia rusticana*) made incidentally in this Department in the course of other work. These observations indicate that under constant conditions horse-radish cuttings show a seasonal variation in regenerating capacity, expressed as the mean number of primordia formed per root-scar in 10–14 days (Fig. 1). The results shown are at present incomplete, but it is hoped to extend them in the future. The point of particular interest, however, is that the regenerating capacity is low during the months of flowering (in *Armoracia*, during May and June); and an inspection of Hudson's graph shows that the same relationship holds for the raspberry (flowering June to August).

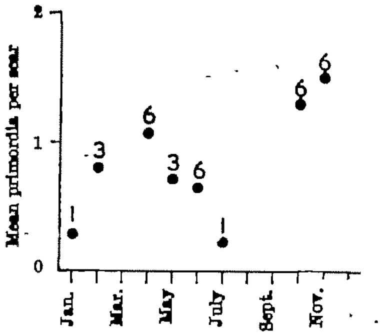

Fig. 1. Seasonal variation in the regeneration of horse-radish root-cuttings. Figures represent number of experiments on which each point is based

Examination of a propagation table given by Graham[2] shows that of twelve species, all regenerating from the roots in the same manner as horse-radish and raspberry, five regenerate most efficiently before flowering, three after flowering, two regenerate most efficiently in the flowering month and also in another month, and two regenerate efficiently only during the flowering months. Similarly, of twelve species which regenerate from stem cuttings, five regenerate most efficiently before flowering, five most efficiently after flowering, and only two actually during flowering.

It is apparent that the antagonism between regenerating capacity and flowering is quite widespread and, apart from its possible biochemical implications, may have an important bearing on competition and survival in such plants.

Sperm Storage and Cross-Fertilization of Spring and Autumn Spawning Herring

This preliminary communication gives the results of some experiments conducted at the Marine Laboratory, Aberdeen, in 1953, as part of a more extensive herring-rearing programme. They show that it is possible to cross-fertilize the two spawning 'types' of herring (*Clupea harengus*) found in the north-east Atlantic, one of which spawns in the spring, the other in the autumn.

To achieve this, a technique of long-term gamete storage is required. Polge, Smith and Parkes[1] first reported that fowl spermatozoa stored in dilute glycerol at − 79° C. remained alive for as long as nine months; Polge and Rowson[2] found that bull spermatozoa remained fertile after storage for nine months under these conditions. Similar methods were therefore applied to the storage of herring gametes.

Ripe spermatozoa and eggs were obtained in March 1953 from spring-spawning herring caught in the Firth of Clyde. Two samples of each of the ovary and testes were removed by dissection and placed in sealed tubes containing a solution of 12·5 per cent glycerol in diluted sea water (one part distilled water to four parts sea water). After an interval of thirty minutes at a temperature of about 8° C., one sample of each was frozen rapidly by placing it in solid carbon dioxide (− 79° C.). The other two samples were cooled slowly by immersing their containers in alcohol to which solid carbon dioxide was added in such quantities as to give a cooling rate of 1° deg. C./min. Rapid cooling was resorted to when the temperature reached about – 80° C. The eggs were found to die, but the spermatozoa remained alive when kept under these conditions. In early September, ripe autumn-spawning herring became available. The stored milt was thawed in water at 40° C. and the eggs from a ripe autumn-spawning herring were fertilized. The rapidly-frozen sperm gave a fertilization of 85 per cent, the slowly-frozen sperm one of 80 per cent. The eggs were placed in a constant-temperature tank at 11·5° C. and 5 per cent of the total number of eggs hatched. This percentage hatching was the same as that of another batch of eggs in the same tank for which both parents were autumn spawners.

This storage technique opens up possibilities for testing the interfertility of closely related fish species and other animals with different spawning times or places. Reproductive isolation is one of the criteria used in defining a species, and experiments such as that described above might be of value to the systematist. It is proposed to extend these experiments to other 'types' of herring and to other species of Clupeoids.

My thanks are due to Dr. J. E. Lovelock, of the National Institute for Medical Research, Mill Hill, London, for his advice on sperm storage, to Mr. B. B. Parrish, of this Laboratory, for generous advice and help on herring matters, and to Mr. D. Mills, for assistance in this work.

Naras Seed Protein

THE naras (*Acanthosicyos horrida*, Hook) is a cucurbitaceous plant, which occurs particularly near Walvis Bay in South-West Africa. The fruit is a small melon consisting of an outer rind and six segments which contain numerous seeds. The fruits and the seeds derived from them were extensively used as foods by the desert dwellers of the area in earlier days, and are still used to some extent in this way. More recently, the seeds have been collected and exported to South Africa, where they have found use in the confectionery industry. Versfeld and Britten[1] found that the seed kernels consist mainly of protein (35 per cent) and fat (53 per cent).

The proteins of oil-free naras seed meal were extracted with 10 per cent sodium chloride and then four volumes of water were added to each volume of the extract, causing precipitation of the extracted protein. The protein obtained resembles edestin[2] in being soluble only in buffers of relatively high salt concentration. Measurements on a Brice–Phoenix light-scattering photometer[3], using the ultrafiltration method of Goring and Johnson[4] for the clarification of the solutions, gave a molecular weight of 343,000 at ionic strength (I) 1·0 and pH 7·8 for this preparation.

In a second preparation the proteins extracted with 10 per cent sodium chloride were precipitated by saturating the extract to 45 per cent with ammonium sulphate. This preparation gave a light-scattering molecular weight of 341,000 at $I = 1·0$ and $pH = 7·9$. Thus, the two preparations probably represent the same protein fraction, and have a molecular weight comparable with values reported for other seed globulins[5].

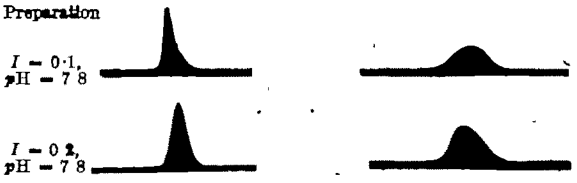

Fig. 1. Electrophoresis diagrams of naras seed protein–sodium dodecyl sulphate complexes

Whereas naras seed protein is only soluble in buffers of high salt content ($I = 1·0$), it is rendered soluble in buffers of low ionic strength ($I = 0·1$) by the addition of 1 per cent sodium dodecyl sulphate. This fact alone seems to indicate that a detergent-protein complex is formed. The electrophoretic diagrams (shown in Fig. 1) obtained for complexes prepared at $I = 0·1$ and $0·2$ at $pH = 7·8$ indicate that these are electrophoretically homogeneous. The light-scattering molecular weights of these complexes are shown in the table.

Preparation	$\frac{dn}{dc}$	Molecular weight	Uptake of sod. dodecyl sulph. (gm./gm protein)
Original protein $I = 1·0$ $pH = 7·8$	0·188	343,000	—
Complex at $I = 0·1$ $pH = 7·8$	0·164	96,000	0·47
Complex at $I = 0·2$ $pH = 7·8$	0·164	163,000	0·47

The molecular weights of the complexes are very much lower than that for the original protein, due to a breakdown of the protein in complex formation. Although the detergent uptake for the two complexes is the same, nevertheless there is a considerable difference in the respective molecular weights. Calculations from the known composition of the complexes have shown that complexes with sodium dodecyl sulphate have been formed in which the weight of protein per molecule of complex is about 56,000 and 110,000 for preparations at $I = 0·1$ and $I = 0·2$ respectively. This suggests breakdown of the original protein molecule into sixths at $I = 0·1$ and thirds at $I = 0·2$.

When arachin was treated with sodium dodecyl sulphate under similar conditions[6], an extensive breakdown of the protein occurred, but the sedimentation constants, and hence molecular weights, at $I = 0·1$ and $0·2$ were of the same order.

Inhibition of *Fusarium culmorum* by *Streptomyces albidoflavus*

THOUGH soil actinomycetes can sometimes elaborate antibiotics when grown in unamended sterile soil[1], it has usually been found necessary to enrich such soils with energy sources in order to demonstrate production of antibiotic[2]. In unsterile soil cultures, production of actinomycete antibiotics in clearly detectable amounts has only rarely been reported[3]. The following investigation was made to determine the ability of *Streptomyces albidoflavus* to inhibit the growth of the fungus *Fusarium culmorum* under a variety of nutritive conditions and particularly with small amounts of readily available carbohydrate—conditions likely to be unfavourable for luxuriant growth of either organism.

When both organisms were seeded at a distance from each other on plates of mineral salt solution agar containing 1 per cent glucose, growth of the fungus towards the actinomycete was checked. With only 0·01 per cent glucose, the check was never complete and fungal hyphæ grew slowly but steadily towards the actinomycete. The effects of other sources of energy, more likely to be present in soil, were then tested. The actinomycete and the fungus were placed at a distance on plain agar buffered to *p*H 7, and dry, finely milled organic matter was spread over each organism but not over the space between the organisms, so that growth of the fungus towards the actinomycete could be observed. On control plates without added organic material, growth of the fungus was slightly inhibited. Strong inhibition was obtained with dried grass. However, with wheat straw, roots, farmyard manure, leaf mould, peat and 'lignin', antagonism was even less than on the control plates with no added material. All these organic materials and clear extracts of them destroyed the antibiotic activity of actinomycete culture filtrates to which they were added. Presumably, on the agar plates, dried grass enabled the actinomycete to produce an amount of antibiotic in excess of that destroyed by it. Bentonite was very effective in removing antibiotic activity of actinomycete culture filtrates, presumably by adsorption. This effect was also exerted, though to a less extent, by other clays and by whole soils. Bentonite, when added to an agar medium, also strongly reduced antagonism between the actinomycete and the fungus.

When both organisms were grown together in sand culture, the addition of bentonite reduced but did not completely prevent inhibition of *F. culmorum* by the actinomycete. Thus, the actinomycete could inhibit the fungus by means other than antibiotic action.

A direct lysis of the contents of the fungal hyphæ by actinomycete mycelium in contact with it was observed in sand culture. This direct attack was prevented or greatly reduced by the presence of bentonite which, presumably, adsorbed the lytic agent. There was evidence that the actinomycete did not influence growth of the fungus in sterile soil either by antibiotic action or by direct attack, but that there was some competition between the organisms for nutrients or space.

In sand cultures there was a direct relation between the amount of glucose supplied and the antagonistic effect of the actinomycete. This relation was also found when bentonite was present, so that a high level of glucose presumably increased competition for limiting nutrients as well as influencing the production of antibiotic secretions. Lysis of the fungus was also most evident at high concentrations of glucose. Survival of both organisms together was favoured by low concentration of glucose. It would appear, therefore, that the conditions which favour the luxuriant development of an organism growing in pure culture may often be those that will tend to prevent its growth in association with others.

An Unknown Acid from Brain Extracts chromatographed on Silica Gel

SINCE partition chromatography on silica gel allows the simultaneous quantitative determination of the individual acids of the polycarboxylic acid cycle[1,2], it became of interest to apply this technique to the measurement of the organic acids in brain tissues. Fig. 1 shows the chromatographic pattern of the

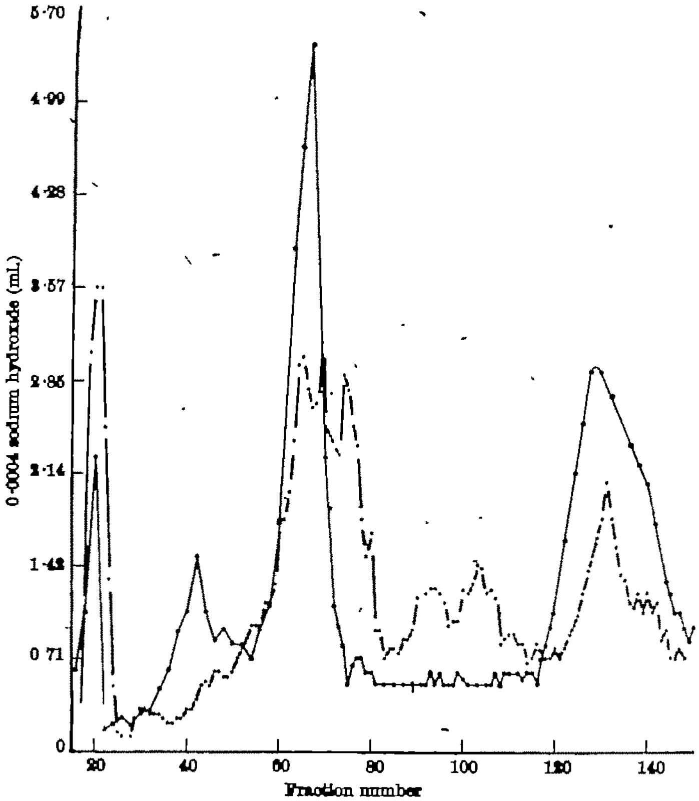

Fig. 1. Typical curves resulting when 1 gm. of brain tissue taken from man and turtle is chromatographed as under refs. 1 and 2. Each fraction represents 1·5 ml. of effluent. The values for human brain tissue might be exaggerated because of anæsthesia used during the operation. Full line, human; broken line, turtle

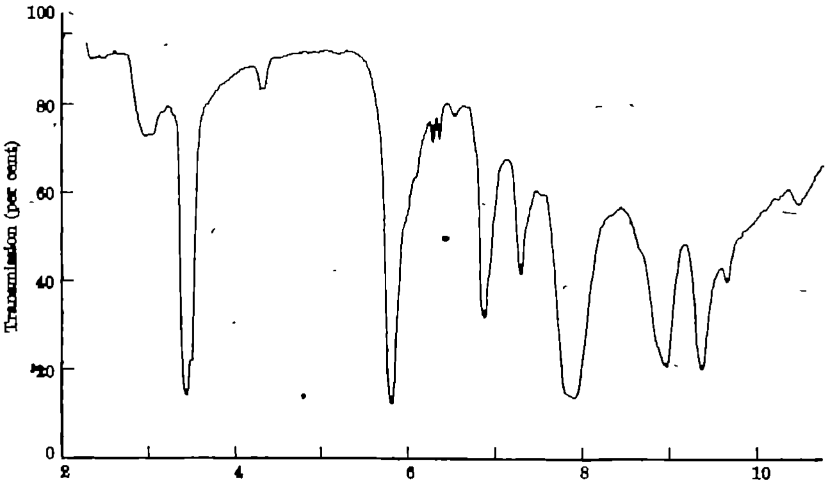

Fig. 2. Infra-red spectrum of an isolated unidentified compound from the brain (fractions 130–150). Film made on sodium chloride crystal

tertiary amyl alcohol – chloroform (50 per cent v/v) extract of human brain. (Identical patterns were found for these extracts from guinea pigs, mice, rabbits, turtles and chickens.) The first peak of the chromatogram (fractions 15–25), composed of a mixture of free and esterified fatty acids[3], was followed by a smaller peak (fractions 40–50) for fumaric acid. Then, there is a large peak (fractions 60–80) representing mainly lactic acid but also small amounts of succinic acid. The lactic acid was identified by measuring the colour produced when concentrated sulphuric acid and P-hydroxydiphenyl were added[4]. The presence of alpha ketoglutarate is often indicated by the presence of a shoulder to the right of this curve.

Finally, there is a pronounced peak due to an unidentified acid (fractions 130–150). When chromatographed with a mixture of oxalic acid and L-malic acid, the unknown acid appears between them on the chromatogram (pattern not shown here). The compound contains 54·3 per cent carbon and 10·4 per cent hydrogen, and the absorption in the infra-red (Fig. 2) shows the OH-stretching vibration (3·4 microns) and the carbonyl stretching (5·8 microns) vibration.

This investigation was aided by a grant from the National Foundation for Infantile Paralysis.

Bacteria-free *Entamoeba Invadens*

Two strains of *Entamoeba invadens* have been growing *in vitro*, on serial transfer, for more than two years in a bacteria-free medium. The culture medium used initially[1] has been simplified and now consists of 10 ml. of 0·75 per cent saline solution to which is added a slice of hamster liver, and the culture is sealed with a layer of petroleum jelly. Liver slices from rats, rabbits, guinea pigs, chickens, pigs and hamsters, have been tested and found to support good growth of the bacteria-free *E. invadens*. The liver cubes used measure 2–4 mm. a side. Limited experiments demonstrate that chicken-breast muscle and rat-heart muscle will also support *in vitro* growth of amœbæ in the absence of bacteria.

The cultures of bacteria-free amœbæ do not normally encyst when grown in this manner, but will remain viable at room temperature for periods up to ten weeks. Our practice is to transfer cultures every three or four weeks. Growth of the amœbæ can be followed by focusing the 16-mm. objective of the microscope on the inner surface of the wall of the culture-tube where the amœbæ adhere.

Liver tissue has been crushed with sterile precautions in a Shiver's tissue grinder and used in place of the liver slice without affecting its growth-promoting qualities. Further, it has been found that liver tissue made into a suspension in saline will support growth of the bacteria-free amœbæ, as will the supernatant of this liver suspension when centrifuged. In our studies, we have added approximately 4 gm. liver tissue to 50 ml. of 0·75 per cent saline, homogenized the liver in a Waring blendor and then centrifuged the suspension at 3,000 r.p.m. for 90 min.; 1 ml. of the supernatant is added to 10 ml. of 0·75 per cent saline solution and the surface of the liquid sealed with a layer of petroleum jelly. The medium thus prepared will support growth of bacteria-free *E. invadens*. The growth-promoting factor present in the supernatant of the liver suspension is almost entirely removed when passed through a Seitz or fritted glass filter.

The results of culture experiments using a dialysing membrane to separate the liver from the amœbæ indicate that the growth-promoting substance in the liver is not dialysable.

Studies to test the effect of heat on the ability of the liver suspension to support growth of *E. invadens* show that 100° C. for 5 min. inactivates the culture medium; 50° C. for 30 min. does not appear to impair its growth-promoting qualities, and liver suspensions heated at 56° C. for 30 min. will support growth although growth of the amœbæ is not so abundant nor do the amœbæ live as long.

The results of studies in progress indicate that garter snakes (*Thamnophis*) experimentally infected with *E. invadens* from bacteria-free cultures may provide useful information on the pathogenesis of amœbiasis. It has already been observed that associated bacteria influence the course and intensity of the amœbic infections and that, of the two strains of *E. invadens* studied in our laboratory, one is more virulent than the other. Finally, these infections show a definite response to subcutaneous injections of emetine, and may well provide a convenient method for the evaluation of amœbicidal drugs.

This work was carried out in the Institute of Parasitology, McGill University, Macdonald College, P.Q., Canada, with financial assistance from the National Research Council of Canada.

Absence of 'Incomplete' Virus Production in certain Influenza Strains

CONCENTRATED allantoic inocula of *PR*8 (influenza [illegible]) virus give rise to particles having the antigenic make-up, hæmagglutinating power and enzymic activity of the seed, but lacking infectivity. Since it bears some resemblance to interference by an unrelated virus, the phenomenon was named 'auto-interference'[1]. The use of this term was rather unfortunate: partly because Ziegler *et al.*[2] had previously proposed it to describe the behaviour of old virus preparations containing a large proportion of non-viable particles, as first observed by Henle and Henle[3]; and partly as it led to the belief that incomplete virus was produced by cells infected by more than one virus particle. Indeed, extensive theoretical predictions have been based on this assumption[4]. Experiments, however, soon revealed that, whatever its mechanism, multiplicity of infection cannot be implicated to account for the facts, as incomplete virus was produced when only 1 per cent of the cells had been infected[5]. This piece of negative evidence brought forward by Cairns and Edney is in itself sufficient to invalidate the hypothesis; here positive proof is furnished that certain strains of influenza virus do *not* produce incomplete particles even under conditions of multiple infection.

Fresh preparations of influenza viruses were inoculated into groups of six 11-day-old eggs, 0·6 ml. volumes of undiluted seed ($10^{8\cdot16}ID_{50}$) or a 10^{-4} dilution being given allantoically. Samples of allantoic fluid were removed at the height of infectivity after 24 and 48 hr. respectively), and each fluid was titrated for hæmagglutinin against 0·25 ml. 1 per cent fowl red cells, and for infectivity in log 0·5-fold steps employing five eggs per dilution. The results obtained with the two classical strains, *PR*8 (*A*) and *LEE* (*B*), are sufficient to establish our thesis; the detailed findings with these and several other strains will be published elsewhere.

Inoculum		Yield*			Evaluation†	
Strain	Dilution	ID_{50}/ml.	*HA*/ml.	*ID*/*HA*	*F*	*P*
*PR*8	10^{0}	7·44	3·34	4·10 ± 0·128	88·56	< 0·001
	10^{-4}	9·97	3·47	6·50 ± 0·214		
LEE	10^{0}	9·56	3·20	6·36 ± 0·136	1·61	~ 0·3
	10^{-4}	9·46	3·22	6·24 ± 0·135		

* Geometric mean and standard error of six parallel experiments expressed in $\log_{10}$ units).

† Results of an analysis of variance; *F* = variance ratio, *P* = probability of the difference being due to chance.

It is evident that whereas the *PR*8 strain shows the typical behaviour described by von Magnus[1], no non-infective virus is produced by the *LEE* strain, although multiple infection has been ensured by the fact that the initial inoculum contained approximately eight times as many ID_{50} as there are infectible cells. Thus the simultaneous infection of a cell by several homologous influenza virus particles does not necessarily result in depression of infective virus production. Consequently, the term 'auto-interference' prejudices our understanding of the underlying mechanism, and should not be used in connexion with incomplete virus production; it is best reserved for the phenomenon to which it has been appropriately applied by Ziegler and his associates[2].

Possible *P–Q* Type Variation in Infectious Laryngotracheitis Virus

FROM an outbreak of acute infectious laryngotracheitis in South Australia[1] a strain of virus was isolated which proved to be highly resistant to neutralization by antisera in the pock neutralization test. On intratracheal inoculation into susceptible birds, it gave rise to typical acute infectious laryngotracheitis in about four days, produced a typical vaccination reaction when given by the cloacal route and gave rise to antibodies fully active against a type infectious laryngotracheitis virus. On primary isolation it showed some degree of resistance to neutralization by its homologous and other infectious laryngotracheitis antisera, but after storage for eight months in the 'dry ice' refrigerator it was almost completely resistant to neutralization by all available antisera (see table). Prior to this outbreak, infectious laryngotracheitis was not known to be present in South Australia despite a careful watch being kept, and no spread of the typical explosive epidemic form of the disease in other flocks has followed this outbreak. A survey of hens throughout South Australia showed that, at the time of isolation of this strain, about 50 per cent of the flocks had birds with demonstrable infectious laryngotracheitis antibodies in their sera.

A similar phenomenon was reported by Burnet[2] in 1936 in strains of infectious laryngotracheitis isolated in Victoria and New South Wales. Burnet stated that "no qualitative antigenic differences can be detected amongst these strains but the epizootic (N.S.W. and BAI) strains are more readily neutralised by immune serum than the enzootic Victorian strains".

POCK NEUTRALIZATION TESTS

Exp. No.	Virus	Antisera	
		Local strain (*A*)	Reference strain (*S*)
1 Fresh virus	*A* *S*	1·0 1·8	1·5 1·9
2 Stored virus	*A* *S*	0·3 1·7	0·0 2·1

The figures are the logarithms of the ratio of foci developing on the experimental to those on the control membranes.

He also recorded a reduced pathogenicity in the Victorian virus. Van der Veen and Mulder[3] described a variation in influenza *A* prime virus in which certain strains (*P*) had a high avidity for antibody, whereas others (*Q*) had a low avidity. Isaacs and Andrewes[4] and later Isaacs[5] confirmed this work and induced *P–Q* and *Q–P* variation in the laboratory. These latter workers advanced the theory that the *Q* variant, being able to survive in the presence of antibody, was a means of inter-epidemic survival.

It appears that the infectious laryngotracheitis and influenza variants have several points in common. Designating the South Australian and Victorian strains of infectious laryngotracheitis as *Q* and the classical strains as *P*, we find that, first, the infectious laryngotracheitis and influenza *Q* strains have a low avidity for antibody whereas the *P* strains of both have a high avidity. Secondly, the *Q* strains of both have been isolated from endemic areas or periods, or at the transition at the opening or closing of an epidemic, whereas the *P* strains of both have as a rule been isolated during epidemics. Thirdly, Burnet demonstrated a lowered pathogenicity in Victorian (*Q*) strains. This has not been demonstrated in the South Australian strains, due possibly to the virus being in an intermediate phase when first isolated. The widespread occurrence of antibodies and the absence of clinically recognizable infectious laryngotracheitis in South Australia and the inter-epidemic history of influenza, however, suggest a reduced pathogenicity. Lastly, the phase variation in influenza has been produced under laboratory control. The evidence for infectious laryngotracheitis in this respect is not at present convincing, but our South Australian strain when first isolated behaved in a manner not inconsistent with Isaacs's mixed *P–Q* (*A*/Persian Gulf/2/52) and, after prolonged storage, behaved as a *Q* strain. This may have been an accidentally induced selection to a *Q*-type variant in a previously mixed strain. It is of interest that our strain of infectious laryngotracheitis was isolated from a flock in which no previous experience of the disease was evident from sera taken within the first week of the epidemic, yet in an area in which some form of it appears to be endemic.

The lytic-symbiotic mutation cycle in bacteriophage described by Boyd[6] appears to serve the same epidemiological function as the influenza and infectious laryngotracheitis variations. In the phage we have, on one hand, a phase which is described as non-pathogenic, inter-epidemic and associated with the maintenance of the species; and on the other, a phase which is 'epidemic', rapidly destructive of its host and provides a wide dissemination of the species. It is not to be expected that the antigenic differences of the animal viruses would be found in the phage variation, as in this case it is not a factor associated with the host–parasite relationship. Boyd, in describing this variation in phage, speculated that were such a cycle present in other viruses it would provide a more convincing explanation of the way in which a virus maintains itself in the inter-epidemic period than a chain of subclinical infections. It is not necessary to postulate a complete symbiotic existence in the inter-epidemic period to be consistent with Boyd's views. Any mutant which is able to survive in the immune host without causing undue symptoms would meet th requirements.

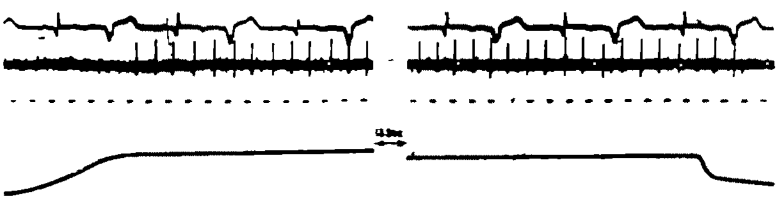
Impulses in Vagal Afferent Fibres from Stretch Receptors in the Stomach and their Role in the Peripheral Mechanism of Hunger

IT has been shown that there are in the cervica vagus of the cat certain afferent fibres which yiel a discharge of impulses a few seconds after a intravenous injection of phenyldiguanide[1] or 5-hydroxytryptamine[2]. The normal functions of thes afferents have now been investigated. Most of thes afferents end in stretch receptors in the wall of th stomach; apparently this is the first description o such receptors.

As shown in the accompanying figure, these fibre yield a discharge of impulses when the stomach i distended with a balloon. Although the threshol of distension necessary to stimulate the receptor varied from 10 to 150 ml., all the gastric receptor so far encountered showed a great similarity in their pattern of response. The discharge in some fibre showed no tendency to become adapted during a maintained distension; in others a slow rate o adaptation occurred; in no case was a rapidly adapting discharge observed. The relation between the degree of distension and the frequency of impulses has been found to be linear. These gastric receptors, for which histological evidence exists[3], would therefore appear to be similar to other well-known stretch receptors, in this particular case their function being to signal the degree of distension of the stomach. The afferents concerned run in the vagi, and these must inevitably play an important part in the various reflexes connected with the stomach. Apart from this, since they must obviously be more active after a meal, they might be responsible for the feeling of satiation. A reduction or absence of these impulses would in that case tend to produce hunger, and on this hypothesis the hunger pangs could be explained as being due to a further reduction in the number of impulses during each contraction. In this connexion the observations and conclusions of previous investigators are relevant[4].



Response of a gastric stretch afferent fibre to a maintained distension of the stomach. From above downwards: e.c.g.; impulses in a gastric stretch fibre; time in 0·1 sec.; intragastric pressure. The frequency of discharge is unaltered throughout the period of distension

A number of drugs when injected into the thoracic rta produce a discharge of impulses similar to that oduced by 100 μgm. phenyldiguanide. Among em are 5-hydroxytryptamine (100 μgm.), lobeline mgm.), nicotine (1 mgm.), adrenaline (100 μgm.), d glucose (0·5 gm.). The depressing effect of renaline on hunger could, therefore, be explained its stimulating action on gastric stretch receptors. rther, a new concept is provided for the association blood-sugar levels and hunger. With the present pothesis it would thus seem possible to reconcile e diverse views and observations on the peripheral echanism of hunger.

My thanks are due to Dr. J. C. Mott for the supply phenyldiguanide, to Messrs. Abbot Laboratories, icago, for the supply of 5-hydroxytryptamine, and Mr. Y. C. Wal for much technical assistance.

ffect of Two Systems of Management on Milk Yield and Body Temperature of Dairy Cattle

IN the winter season in Egypt, cattle are either ept indoors and provided with berseem (*Trifolium lexandrinum*), or taken to the fields and fed with he same ration for a period of about ten hours uring the day. The experiment described here was arried out at the University Experimental Farm, lexandria, in order to study the effect of the two ystems of management on milk-yield and body-emperature of dairy animals.

Two groups of native cows, each of three individuals, early in the same stage of lactation, were subjected o the indoor and the outdoor conditions for ten days lternately for a total period of 80 days. Therefore ach group of cows spent 40 days in each of the wo systems. Milk yield was recorded three times daily, and the rectal temperature was read at each milking. The average results obtained are given in Table 1.

There are no significant differences between the milk yield and body-temperature of the cows in the two systems. These results might only be expected in certain conditions. However, the average temperature in the stable during the period of study ranged between 13·4° and 21·5° C., whereas the corresponding atmospheric temperature was 12·5° and 19·7° C. respectively.

Table 1

Occurrence of *Pterophyllum* in the Parsora Beds, South Rewa, India

DURING February–March 1953, a collection of fossil leaf impressions was made by me from several localities of the South Rewa Gondwana basin, including the well-known locality of Parsora, the floral assemblage of which raised a long-held controversy regarding the age of these beds and their position in the Gondwana system of India. The flora will be described in detail elsewhere. In this communication, I wish to record the finding of two specimens of a hitherto unreported frond recalling *Pterophyllum*. The frond (Fig. 1) is incomplete, pinnate, with a stout and straight rachis measuring 17 cm. in length; 6 cm. in breadth; pinnæ linear, closely set, more or less equal in breadth with one exception, attached to the rachis at right angles and by the whole of their slightly decurrent bases; maximum length exposed of the pinnæ 10 cm. and average breadth 3 cm.; veins many, averaging fifty, distinct, 0·5–0·8 mm. apart, usually bifurcating close to their emergence, where they take a narrow upward curve and then run parallel to the edge of the pinna, rarely showing bifurcation again.

In general appearance and form, the Parsora specimens bear some resemblance to *Nilssonia princeps* (Old. and Morr.) Seward, and to certain large fronds of *N. compta* (Phillips) Bronn[1]. Since not many specimens are available for study at present, it is difficult to say whether on the other side of the frond, which is not exposed to view, the pinnæ are

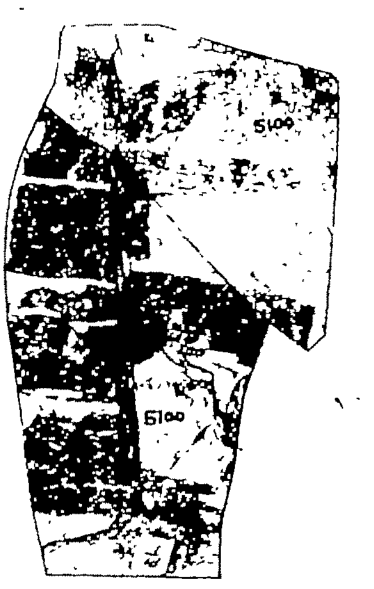

Fig. 1. *Pterophyllum* sp. from the Parsora beds (× about ½)

continuous over the rachis as is characteristic of *Nilssonia*. However, the pinnæ in my specimens seem to be laterally attached as in *Pterophyllum*. In addition to this, the bifurcation of the veins close to their emergence and the presence of almost equal pinnæ are strongly suggestive of *Pterophyllum*. I am, therefore, inclined to believe that these fronds belong to *Pterophyllum*.

The age of the Parsora beds is still in dispute and, although a definite opinion cannot be expressed at present, the vertical range of some of the important plant fossils which reflect upon the age of the Parsora flora can be briefly stated here. *Danaeopsis hughesi*[2], which occurs in abundance at Parsora, ranges from Keuper to Rhætic. Another Parsora species, namely, *Thinnfeldia odontopteroides*[3], is characteristic of Rhætic or Upper Triassic. The genus *Pterophyllum*[4], which has now been found in the Parsora beds, is known to range from the Upper Carboniferous to the Lower Cretaceous, but it is especially characteristic of the Keuper and Rhætic floras.

My thanks are due to Dr. K. R. Surange for his helpful suggestions.

Vaginal Cornification of the Mouse produced by Œstrogens *In vitro*

Several workers have successfully grown parts of the genital tract in tissue culture, but only a few studies have been concerned with the action of œstrogens under these conditions. Gaillard[1] was able to stimulate the uterus and seminal vesicles with œstrone, whereas Emmens and Ludford[2] failed to induce keratinization in explants of rat vagina with œstradiol-3 : 17β. Recently, we have successfully cultured the vagina of the mouse and produced keratinization by the addition of œstrogens to the culture medium.

Three six-day old litter-mates were taken from a mixed albino stock. The genital tract was dissected out and the vagina cut into six rings, each being spread on the surface of the medium in a hanging-drop preparation. This medium consisted of two drops of plasma from a cock seven months old, and one drop of 1 : 1 extract with Tyrode solution of a chicken embryo of eleven days incubation. Two explants from each mouse were cultivated on the basic medium alone (control group), two had in addition 0·01 ml. of Tyrode solution containing 0·006 μgm. of œstradiol-3 : 17β (low-dose group) and two had 0·01 ml. of Tyrode solution containing 0·06 μgm. of œstradiol-3 : 17β (high-dose group). The cultures were incubated at 37·5° C. for three or four days and examined daily.

From the second day onwards all explants showed a healthy outgrowth, usually of both epithelium and fibroblasts. Before incubation the explants showed a border of undifferentiated epithelium, two to three cells thick, on the inner or outer margins of the ring of tissue, but after twenty-four hours incubation the epithelium was usually visible on both inner a outer margins. At twenty-four hours it was still the simple 'unstimulated' type in all explants. 48 and 72 hr. the epithelium of the control grou remained unchanged, but most of the explan treated with œstradiol showed thickening and son degree of stratification of the epithelium. In thes several layers of flattened cells appeared above t undifferentiated basal layer, and above them t most superficial layer of cells appeared swollen. Suc changes are typical of the œstrogen-stimulated vagin epithelium *in vivo*[3]. Thickening and stratificatio became more pronounced as the time of incubatio increased, and at 72 and 96 hr. some explants ha eight to twelve layers of flattened cells beneath a ver swollen superficial layer. At 96 hr. some explants the control group showed slight thickening in a fe regions. Under polarized light the flattened cells the stimulated epithelium showed strong birefringen in the plane parallel to the basement membrane, bu the unstimulated epithelium was not birefringent.

Most cultures were kept for 96 hr. and were the fixed in Zenker with 5 per cent acetic acid, embedde in paraffin wax, sectioned serially and stained i Mayer's hæmalum, picric acid and eosin. Four c the control cultures were treated in this way. A were healthy and showed no evidence of stimulatio Five of the cultures treated with the low dose c œstradiol-3 : 17β were examined. Keratinization wa observed in three of the cultures, and stratification an

(2) 96 hr. in medium containing 0·06 μgm. œstradiol-3 : 17β; stratified epithelium with keratinized cells beneath a superficial layer

ssible keratinization were observed in the fourth. ne fifth was unhealthy and showed no sign of stimution other than the prominent layer of superficial lls. Four of the cultures which received the high dose œstradiol-3 : 17β were also examined. All were althy; two were keratinized, one became stratified d possibly keratinized, and one failed to respond. he histological appearance of the epithelium in conol and in treated explants, respectively, is shown in gs. 1 and 2.

In more recent work, the above experiments have en repeated with some modifications of technique, ith œstrone, œstriol, œstriol glucuronide, œstradiol: 17β, equilin and diethylstilbœstrol. Similar results ve been obtained; a full description will be given sewhere.

The results reported above indicate that œstrogens e capable of producing vaginal cornification *in tro*. This finding is important in discussions of e mode of action of these hormones. By means the double-vaginal pouch technique, Robson and dler[4] and Emmens[5] showed that the intravaginal tion of true œstrogens is purely local. Our results rectly corroborate these earlier findings and render ntenable the recent thesis of Szego and Roberts[6] at œstrogens have to be 'activated' by the liver efore they are capable of exerting their action.

Hechter, Lev and Soskin[7] believe that the developent of hyperæmia is essential for cornification of e vagina. Our results do not support this view, ut suggest that the œstrogens act primarily on the sponding cells.

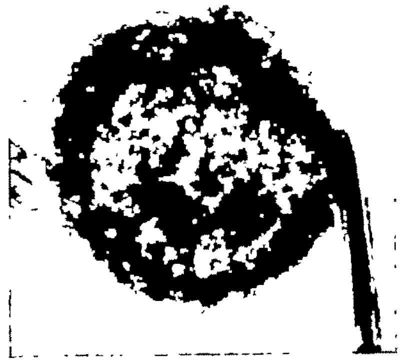
Acetocarmine as a Nuclear Stain in Rhodophyceae

IN recent years, the earlier acetocarmine technique f Belling has been modified by Godward[1] and also ave and Pocock[2] for use in staining the nuclei of arious Conjugales and Volvocales respectively. So ar as is known, the technique has not been applied reviously to the Rhodophyceae, and at the suggestion f Dr. K. M. Drew, therefore, an attempt has been ade to stain some members of this group by this ethod.

Of those available for use, the following have tained successfully: *Porphyridium cruentum* (Ag.) aeg., *Porphyra umbilicalis* (L.) J. Ag., *P. umbilicalis* var. *laciniata* (Lightf.) Ag., *P. linearis* Grev., *Batrachospermum fruticulosum* Drew, *Antithamnion spirographidis* Schiffner, *Antithamnionella sarniensis* Lyle. and *Griffithsia setacea* C. Ag. (= *G. flosculosa* Batt.). However, *Polyides caprinus* (Gunn.) Papenf., *Furcellaria fastigiata* Lamour. and *Dumontia incrassata* Lamour. have not stained satisfactorily, and this may be due to the thick mucilaginous cell walls and large amount of floridean starch that surrounds the nucleus in some of the cells of these species.

The method which has been employed is a modification of those previously tried and is as follows: (1) Fix material in 3 : 1 absolute alcohol–acetic acid for ten minutes to a few hours. Best results are obtained when the material is stained soon after fixation. (2) Bring material down to water through 90, 70, 50 and 30 per cent alcohols. (3) Wash (two or three changes) with distilled water. (4) Mordant in freshly prepared 4 per cent iron–alum for 5–20 minutes. (5) Wash (two or three changes) with distilled water. (6) Place material on slide and add acetocarmine; cover, and heat to boil (repeat boiling twice or thrice). (7) If material requires spreading, squash with cloth-covered finger. (8) Add fresh acetocarmine to margin of cover-glass, heat again and keep slide warm for ten minutes on hot plate. (9) Make permanent according to (McClintock's) method recommended by Manton[3]. (Temporary preparations invariably look more elegant than permanent ones.)

As the method is a rapid one, it has been found very useful in determining times of nuclear divisions, for example, in tetrasporangia and germinating tetraspores. In illustration of the results, a photograph of the first mitotic division in a germinating tetraspore of *Antithamnion spirographidis* Schiffner is reproduced herewith.



Prophase of first mitotic division in germinating tetraspore of *Antithamnion spirographidis* Schiff. Permanent acetocarmine. (× 1,000)

Detection and Recording of Optical Transients by Photo-multipliers

THE use of photo-multipliers for the detection and recording of optical transients is well known in the fields of gaseous discharge and of scintillation counting. In both these fields, involving time-intervals short compared with a microsecond, the limit of detection of the system is set by the shot noise associated with the photo-current and not by the thermionic emission from the cathode. The thermionic emission from the cathode of a photo-multiplier is usually quoted as about 10^{-15} amp./cm.^{2} or approximately 10^{-14} amp. for the whole cathode. This corresponds to an average rate of emission of electrons of approximately one electron in ten micro-seconds, and the probability of emission of an electron during any interval of time short compared with a microsecond is small.

The shot noise associated with a photo-current I_0 is given by:

$$(i_n)_{\text{rms}} = (2eI_0.\delta f)^{1/2}, \qquad (1)$$

where δf is the bandwidth of the system and e is the electronic charge.

If we take the limit of detection to be:

$$(i_n)_{\text{rms}} = I_0, \qquad (2)$$

then

$$I_0 = 2e.\delta f. \qquad (3)$$

If the output current of the photo-multiplier, gI_0, where g is the gain, is being used to produce a voltage across an anode resistor R in parallel with the anode and stray capacitance C, then we may write approximately

$$\delta f = 1/2\,CR, \qquad (4)$$

and therefore

$$I = ge/CR, \qquad (5)$$

where I is the output current of the photo-multiplier.

The output voltage generated across the anode resistor R is:

$$V = RI = ge/C. \qquad (6)$$

From equation (6) we see that this minimum value of V is independent of the value of R, varies directly as the gain of the photo-multiplier and is inversely proportional to the capacitance C. In the applications quoted above, the amount of light available is usually not much greater than the minimum amount that can be detected, and a certain amount of amplification of the resulting signals is needed. By inserting values of g and C in equation (6), the minimum voltage which the amplifier will be required to amplify may be determined. The output capacitance of an *R.C.A.* 931-*A* type of photo-multiplier is approximately 5 pF., and therefore a value of 10 pF. may be taken for C. The maximum gain obtainable from such a photo-multiplier is around 10^8, and therefore the minimum value of V for detection will be 0·016 volt.

From equation (5) we see that the minimum photo-current for detection corresponds to the release of one photo-electron in a time of CR. Since the efficiency of the photo-cathode of the 931-*A* type of photo-multiplier is such that approximately ten incident quanta are required to release one photo-electron, the minimum detectable light flux will correspond to the incidence of approximately ten quanta on to the cathode in a time of CR.

The above analysis of the minimum detectable signals neglects the contribution of the secondary emission to the noise-level observed at the anode of the photo-multiplier, as this has been shown to be small. It also assumes that the thermal agitation noise in the resistor R produces a noise voltage wh is small compared with the amplified shot noise g The thermal agitation noise in a resistor is given b

$$(v_n)_{\text{rms}} = (4kTR\,\delta f)^{1/2}. \qquad ($$

Substituting for δf from equation (4), we have:

$$(v_n)_{\text{rms}} = (2kT/C)^{1/2}. \qquad ($$

In the limit, when the noise due to the resistor equal to the amplified shot noise,

$$g = (2kTC/e^2)^{1/2}. \qquad ($$

The above value of g represents the minimum ga which may be used to ensure that the noise acro the resistor R is not the limiting factor in the d tection of small values of light flux. It will be se that this minimum value of gain is independent the value of R but depends on the value of C. F a value of C of 10 pF., g_{min} is 2,500.

The above analysis has been based on the detecti of a light flux, and a similar analysis may be pe formed where the object is the measurement of light flux to an accuracy of one part in N. To atta this accuracy, the minimum number of phot electrons which must leave the photo-cathode in th minimum resolution time τ is N^2 and therefore th minimum output current is:

$$I_{\text{min}} = N^2\,ge/\tau. \qquad (1$$

Tables 1 and 2 show the minimum output curren required to maintain accuracies of 10 and 1 per ce respectively.

Table 1. MINIMUM OUTPUT CURRENTS FOR ACCURACIES OF 10 PER C

Gain	Resolution time		
	10^{-9} sec.	10^{-8} sec.	10^{-7} sec.
10^4	160 μamp.	16 μamp.	1·6 μamp.
10^5	1·6 m.amp.	160 μamp.	16 μamp.
10^6	16 m.amp.	1·6 m.amp.	160 μamp.
10^7	160 m.amp.	16 m.amp.	1·6 m.amp.
10^8	1·6 amp.	160 m.amp.	16 m.amp.

Table 2. MINIMUM OUTPUT CURRENTS FOR ACCURACIES OF 1 PER CE

Gain	Resolution time		
	10^{-9} sec.	10^{-8} sec.	10^{-7} sec.
10^4	16 m.amp.	1·6 m.amp.	160 μamp.
10^5	160 m.amp.	16 m.amp.	1·6 m.amp.
10^6	1·6 amp.	160 m.amp.	16 m.amp.
10^7	16 amp.	1·6 amp.	160 m.amp.
10^8	160 amp.	16 amp.	1·6 amp.

The use of the *R.C.A.* 931-*A* type of phot multiplier enables currents of up to about 80 m.am to be obtained with a resolution time of aroun $\frac{1}{2} \times 10^{-8}$ sec., and therefore the maximum gain whic may be used to obtain an accuracy of 1 per cent approximately 10^5. A gain of 10^7 lowers the accurac which can be obtained to 10 per cent.

The above analysis shows that it is as importan to endeavour to increase the maximum linear curren which can be drawn from a photo-multiplier as t endeavour to increase the maximum gain which ca be obtained.

I acknowledge the grant of an I.C.I. Researc Fellowship which made this work possible.

SCIENCE MASTERS' ASSOCIATION (at Oxford).—Annual Meeting.

Tuesday, December 29

At 8 p.m. (in the Hall of Rhodes House, South Parks Road, Oxford).—Sir Cyril Hinshelwood, F.R.S.: "Thoughts on the Evolution of a Scientific Problem" (Presidential Address).

Wednesday, December 30—Saturday, January 2

GEOGRAPHICAL ASSOCIATION (at the London School of Economics, Houghton Street, Aldwych, London, W.C.2)—Annual Conference.

Friday, January 1

BRITISH PHYCOLOGICAL SOCIETY (in the Department of Botany, University College of London, Gower Street, London, W.C.1), at 10.30 a.m.—Symposium on "Algal Physiology and Biochemistry. Speakers: Dr. G. E. Fogg, Dr. L. Fowden, Mr. M. R. Droop, Dr. C. P. Spencer and Mr. F. J. Taylor 4 p.m.—Second Annual General Meeting.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

PHYSICAL CHEMIST or ORGANIC CHEMIST (with physical leanings), for research into fundamental aspects of the oxidation of carbon—The Clerk, Birkbeck College, Malet Street, London, W.C.1 (January 2).

PHYSICIST (with a university degree in science and at least three years experience as a physicist in a radiotherapy unit) in the Department of Health, Southern Rhodesia Government—The Secretary, Southern Rhodesia Government, Rhodesia House, 429 Strand, London, W.C.2 (January 15).

PROFESSOR OF AGRICULTURAL BOTANY and a PROFESSOR OF MATHEMATICS—The Registrar, The University, Reading (January 25).

CHAIR OF BOTANY in the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (January 31).

PROFESSOR OF AGRICULTURE in the University of Adelaide, and HEAD OF THE DEPARTMENT OF AGRONOMY in the WAITE AGRICULTURAL RESEARCH INSTITUTE of the University—The Registrar, University of Adelaide, Adelaide, South Australia (January 31).

SENIOR LECTURER IN ANIMAL HUSBANDRY at the New England University College, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Armidale, February 1).

ASSISTANT DIRECTOR to take charge of a team of chemists, physical chemists, physicists and mathematicians engaged on a comprehensive scientific study of the physical and chemical properties of rayon and synthetic fibres and problems associated with the application of these fibres—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester.

BIOCHEMIST (senior grade) to the Rochdale Group of Hospitals—The Group Secretary, Birch Hill Hospital, Rochdale, Lancs.

CHAIR OF GEOGRAPHY—The Secretary and Registrar, The University, Southampton.

ENGINEER, PHYSICIST or MATHEMATICIAN (with first- or second-class honours degree in an appropriate subject, with at least three years relevant postgraduate experience) in the Ministry of Supply, Research Branch, Tolworth, Surbiton, to work on design and development of wide range of survey, photographic and printing equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A 194/53A.

GRADUATE ASSISTANT (with degree in physics and/or mathematics, and an interest in scientific publication) for work in editorial department which will include preparation of mathematical and physical material for publication, and supervision of small scientific library—The Secretary-Editor, The Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7.

HONOURS PHYSICIST for research on the friction and lubrication of textile materials—The Director, Shirley Institute, Manchester 20.

LECTURER (with experience of rubber or similar high polymers and knowledge of electronics) IN PHYSICS—The Clerk, National College of Rubber Technology, Northern Polytechnic, Holloway, London, N.7.

LECTURER (with good honours degree in physics or equivalent qualification, and with suitable teaching, industrial or research experience) IN PHYSICS, at the College of Technology and Commerce, Cardiff—The Director of Education, City Hall, Cardiff.

METALLURGIST (qualified) to lead research team on the weldability of alloy steels—The Secretary, British Welding Research Association, 29 Park Crescent, London, W.1

PHYSICIST (with first- or second-class honours degree in science, and preferably with five years experience as a hospital physicist) in the Medical Department of Hong Kong, for duties in the Radiotherapy Sub-Departments, working in collaboration with the Radiologist in technical aspects of radiotherapy and maintenance and care of specialized plant and equipment—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.117/51/013.

PHYSICIST (with practical experience of radiation physics and electronics)—St. Anne's City Hospital for Diseases of the Skin and Cancer, Northbrook Road, Dublin.

RESEARCH CHEMIST (with at least a good honours degree in chemistry, with appropriate subsidiary subjects) to undertake fundamental research on products of a natural origin—The Chief Research Chemist, Forestal Central Laboratory, Harpenden Rise, Harpenden.

SENIOR LECTURER (with a good honours degree, with industrial and research experience) IN THE HEAT ENGINES SECTION of the Department of Civil and Mechanical Engineering—The Secretary, The Royal Technical College, Glasgow.

SURVEY ENTOMOLOGIST (with good degree, in entomology) in the East African Tsetse and Trypanosomiasis Research and Reclamation Organization, for work in connexion with tsetse surveys in Kenya, Uganda and Tanganyika—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.77/88/04.

TECHNICAL LIBRARIAN (with a knowledge of telecommunications, electrical engineering or physics, and technical library experience)—The Director of Research, British Telecommunications Research, Ltd., Taplow Court, Bucks.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

The Webster Plass Collection of African Art. (The Catalogue of a Memorial Exhibition held in the King Edward VII Galleries of the British Museum, 1953.) By William Fagg. Pp. 47+46 plates. (London: British Museum, 1953.) [411

Ministry of Fuel and Power: Safety in Mines Research Establishment. Thirty-First Annual Report on Safety in Mines Research, 1952. Pp. 76+4 plates. (London: H.M. Stationery Office, 1953.) 3s. net. [411

National Advisory Committee on the Employment of Older Men and Women. First Report. Pp. 62. (Cmd. 8963.) (London: H.M. Stationery Office, 1953.) 2s. net. [411

Report on the Work of the British Council for the Year ended 31st March 1953. Pp. v+105. (London: British Council, 1953.) 2s. 6d. [411

The Manchester Public Libraries. The 101st Report of the Libraries Committee, 1952–53. Pp. ii+36+8 plates. (Manchester: Manchester Public Libraries, 1953.) [411

Proceedings of the University of Durham Philosophical Society. Vol. 11, No. 6: Observations on the Flora of the Isle of Lewis, Isle of Harris and the Shiant Isles in 1952. By Dr. J. W. Heslop Harrison. Pp. 83–90. Vol. 11, No. 7: The Tholeiite Dyke at Cowgate, Newcastle-upon-Tyne; The Carboniferous Igneous Rocks of the Kelso District. By Dr. S. I. Tomkeieff. Pp. 91–102+1 plate. Vol. 11, No. 8: Notes on the Birds of Lake Elmenteita, Kenya Colony. By M. W. Ridley and Lord R. C. Percy. Pp. 103–118+4 plates. (Durham: University of Durham Philosophical Society, 1953.) [411

Philosophical Transactions of the Royal Society of London. Series A. Mathematical and Physical Sciences. No. 910, Vol. 246 (29 October 1953): Finite Plane Strain. By J. E. Adkins, A. E. Green, and R. T. Shield. Pp. 181–213. 7s. 6d. No. 911, Vol. 246 (5 November 1953): Wave Functions of the Hydrogen Molecular Ion. By D. R. Bates, Kathleen Ledsham and A. L. Stewart. Pp. 215–240. 6s. No. 912, Vol. 246 (5 November 1953): Theoretical Studies in Nuclear Structure. IV. Wave Functions for the Nuclear p-Shell. Part B. $(p^n/p^{n-1}p^1)$ Fractional Parentage Coefficients. By J. P. Elliott, J. Hope and H. A. Jahn. Pp. 241–279. 9s. Series B. Biological Sciences. No. 648, Vol. 237 (4 November 1953): Form and Habit in *Pinna Carnea* Gmelin. By Prof. C. M. Yonge, F.R.S. Pp. 335–374. (London: Cambridge University Press, 1953.) [411

Annual Report of the Director of the Meteorological Office for the Year April 1, 1952 to March 31, 1953. Pp. 56. (M.O. 573.) (London: H.M. Stationery Office, 1953.) 2s. net. [611

Nimonic Alloys in Aircraft Gas Turbines. Pp. 12. (Birmingham: Henry Wiggin and Company, 1953.) [611

International Society of Soil Science. Joint Meeting of Commission II (Soil Chemistry) and Commission IV (Soil Fertility and Plant Nutrition), Dublin, July, 1952. Transactions. Vol. 1: Pp. 235. Vol. 2: Pp. 404. (Dublin: Department of Agriculture, 1953.) 2 volumes 120s.

Discussions of the Faraday Society. No. 13, 1953: The Physical Chemistry of Proteins. Pp. 288+4 plates. 35s. net. No. 14, 1953: The Reactivity of Free Radicals. Pp. 256+3 plates. 35s. net. (London: The Faraday Society, 1953.) [911

British Hat and Allied Feltmakers Research Association. Sixth Annual Report of the Director of Research, for the year ending August, 1953. Pp. 16. (Manchester: British Hat and Allied Feltmakers Research Association, 1953.) [1111

Bulletin of The British Museum (Natural History). Botany. Vol. 1, No. 3: Notes on Podostemaceae for the Revision of the Flora of West Tropical Africa. By G. Taylor. Pp. 51–59. 6s. Zoology. Vol. 2, No. 3: On *Sirpus*, a Genus of Pigmy Cancroid Crabs. By Isabella Gordon. Pp. 43–65. 6s. (London: British Museum (Natural History), 1953.) [1111

Air Ministry. Meteorological Office. Geophysical Memoirs No. 91 (Sixth Number, Volume 11): Vertical Profiles of Mean Wind in the Surface Layers of the Atmosphere. By E. L. Deacon. Pp. iv+68+1 plate. (London: H.M. Stationery Office, 1953.) 4s. 6d. net. [1111

Department of Industry and Commerce. Meteorological Service. Geophysical Publications, Vol. 4, No. 1: The Frequency of Heavy Daily Rainfalls in Ireland. By W. A. Morgan. Pp. 18. (Dublin: Stationery Office, 1953.) 4s. 6d. [1111

The Future Organization of the United Kingdom Atomic Energy Project. Pp. 10. (Cmd. 8986.) (London: H.M. Stationery Office, 1953.) 6d. net. [1211

Supplementary Data on the Nimonic Alloys. Pp. 8. (Birmingham: Henry Wiggin and Company, Ltd., 1953.) [1211

Aero Research Technical Notes. Bulletin No. 130: Structural Adhesives for Metal Aircraft. Pp. 8. (Duxford: Aero Research, Ltd., 1953.) [1211

The Pharmaceutical Society of Great Britain. Calendar 1953–54. Pp. vi+300. (London: Pharmaceutical Society of Great Britain, 1953.) 12s. 6d. [1311

Other Countries

Research Bulletin of the East Panjab University. No. 25 (Zoology): The External Morphology of *Diprion Pini* (L.) (Symphyta-Hymenoptera). By Dr. G. L. Arora. Pp. 21. 2/8/- rupees. No. 26 (Veterinary): A preliminary Investigation to Study the Effect of Feeding Concentrates on the Frequency of Oestrus in Cattle. By G. P. Sharma and K. R. Suri. Pp. 23–32. 1/2/- rupees. No. 27 (Zoology): The Sperm of *Lepisma Domestica*. By Vishwa Nath and C. L. Bhatia. Pp. 33–43. 2 rupees. No. 28 (Chemistry): Viscosity of Condensed Phosphates in Solution. By Ram Chand Paul, Kundan Lal, V. S. Gaind and S. S. Bawa. Pp. 44–49. 13 annas. No. 29 (Chemistry): Antimalarials in Quinazolone Series. By Megh Kumar Jain and K. S. Narang. Pp. 50–53. 11 annas. No. 30 (Chemistry): Potentiometric Studies in Oxidation-Reduction Reactions. Part 16: Oxidation with Chloramine-T. Determination of Organic Substances. By Balwant Singh, Apar Singh and Mohan Singh. Pp. 54–66. 1/12/- rupees. (Hoshiarpur: East Panjab University, 1953.) [2810

Publications de l'Institut National pour l'Étude Agronomique du Congo Belge. Rapport Annuel pour l'Exercice 1952. Pp. 396. 160 francs. Bulletin Climatologique Annuel du Congo Belge et du Ruanda-Urundi, Année 1952. (Bureau Climatologique—Communication No. 7.) Pp. 145. 120 francs. (Bruxelles: Institut National pour l'Étude Agronomique du Congo Belge, 1953.) [2910

World Health Organization. Technical Report Series No. 70: Joint UN/WHO Meeting of Experts on the Mental-Health Aspects of Adoption. Final Report. Pp. 19. (Geneva: World Health Organization; London: H.M. Stationery Office, 1953.) 1s. 3d.; 0.15 dollars; 0.60 Swiss francs; 50 French francs. [2910

World Health Organization. Technical Report Series No. 71. Expert Committee on Leprosy. First Report. Pp. 28. (Geneva: World Health Organization; London: H.M. Stationery Office, 1953.) 1s. 6d.; 0.20 dollars; 0.80 Swiss francs; 65 French francs. [2910

Indian Forest Bulletin No. 169 (New Series). Silviculture. The Tree Species of the Tropical Evergreen Ghat Forests of Kanara (Bombay), and their Rate of Growth. By G. S. Mathauda. Pp. ii+23. 1/8/- rupees; 2s. 3d. [2910

Berichte des Deutschen Wetterdienstes. No. 2: Der Einfluss des vertikalen Impulsaustausches auf synoptische Druck-und Temperaturgebilde. Von Dr. Hans Klaus Meyer. Pp. 27. 5 D.marks. No. 3: Differential-gleichungen der quasigeostrophischen Wetterentwicklung von Druckfeldern mit schwachen, mittleren und starken Windgradienten in der Erdatmosphäre und ähnlichen rotierenden Systemen. Von Dr. H. Stümke. Pp. 19. (Bad-Kissingen: Deutschen Wetterdienstes, 1953.) [3010

Chicago Natural History Museum. Fieldiana—Zoology. Vol. 34, No. 11: A New Fish from North Borneo, Genus *Tetraodon*. By Robert F. Inger. Pp. 149–152. 15 cents. Fieldiana—Botany. Vol. 26, No. 2: Orchids of Guatemala. By Oakes Ames and Donovan Stewart Correll. Pp. iv+399–728. (Chicago: Chicago Natural History Museum, 1953.) 5 dollars, cloth; 4 dollars, paper. [411

Norsk Polarinstitutt. Meddelelser Nr. 72: Drivisen ved Svalbard 1924–1939. Av Kirsten Omdal. Pp. 21. 2,50 Kr. Meddelelser Nr. 73: Noen iakttagelser over isbreenes tilbakegang i Hornsund, V. Spitsbergen. Av. A. Heintz. Pp. 7–36. 3,50 Kr. Meddelelser Nr. 74: Preliminary Note on the Geology of Western Dronning Maud Land. By E. F. Roots. Pp. 17–33. 2,00 Kr. Meddelelser Nr. 75: The Current of the Coast of Queen Maud Land. By H. U. Sverdrup. Pp. 239–250. 1,00 Kr. Meddelelser Nr. 76: Flateinnholdet av breer og snefonner i Norge. Av Adolf Hoel. Pp. 109–124. 1,50 Kr. (Oslo: I kommisjon hos Brøggers Boktr. Forlag, 1953.) [411

Académie Royale de Belgique. Classe des Sciences. Mémoires, Tome 28, Fascicule 4: Sur la possibilité de déduire immédiatement, du diagramme différentiel de Wolf, la distance et le pouvoir absorbant d'une nébuleuse obscure, ainsi que la dispersion σ des magnitudes absolues. Par J. Warzée. Pp. 42. (No. 1642.) (Bruxelles: Palais des Académies, 1953.) 40 francs. [411

Metropolitan Life Insurance Company. Statistical Bulletin. Vol. 34, No. 9: Widowhood and Its Duration. Pp. 12. (New York: Metropolitan Life Insurance Company, 1953.) [411

U.S. Department of Agriculture. Leaflet No 345: Insects in Farm-Stored Wheat—How to Control Them. Pp. 8. (Washington, D.C.: Government Printing Office, 1953.) 10 cents. [411

Imperial College of Tropical Agriculture. A Report on Cacao Research 1945–1951. Pp. 132. (St. Augustine, Trinidad: Imperial College of Tropical Agriculture, 1953.) [411

Pacific Science Association. Organizations Engaged in Scientific Research on an International Scale in the Pacific. Pp. 32. (Honolulu: Pacific Science Association, 1953.) [911

Bulletin of the American Museum of Natural History. Vol. 103, Article 1: A Historical Review of the Mollusks of Linnaeus. Part 2—The Class Cephalopoda and the Genera *Conus* and *Cypraea* of the Class Gastropoda. By Henry Dodge. Pp. 134. 1.75 dollars. Title Page and Index to Vol. 102, 1953. Pp. viii+483–485. (New York: American Museum of Natural History, 1953.) [911

Sudan Government: Ministry of Agriculture. Bulletin No. 7: Pump Scheme Management on the White Nile. By J. R. Thomson. Pp. 73. (Khartoum: Agricultural Publications Committee, 1951.) 25 piastres; 5s. [911

State of Illinois: Department of Registration and Education. Division of the State Geological Survey. Report of Investigations—No. 162: Geologic Aspects of Radio Wave Transmission. By M. William Pullen. Pp. 73. (Urbana, Ill.: State of Illinois, Department of Registration and Education, 1953.) [911

United States Department of Commerce. National Bure Standards Circular 542: Graphs of the Compton Energy- Relationship and the Klein-Nishina Formula from 10 Kev to Mev. By Ann T. Nelms. Pp. iv+89. (Washington: Govern Printing Office, 1953.) 55 cents.

United States Department of Agriculture. Agricultural Rese Administration: Bureau of Entomology and Plant Quaran Picture Sheet No. 27: Chinch Bug. (Washington: Governm Printing Office, 1953.)

Report for years 1949–51 of the Botanical Division of the Rub Research Institute of Malaya. Pp. 112. (Kuala Lumpur: Rub Research Institute of Malaya, 1953.)

Journal of the Rubber Research Institute of Malaya. Vol. Communication 284: Stability and Mineral Composition of He Latex. By M. W. Philpott and D. R. Westgarth. Vol. 14, Commu cations 285, 286: Factors Affecting the Measurement of Str By L. L. Best. Fractions from Hevea Brasiliensis Latex Centrifu at 59,000 g. By A. S. Cook and B. C. Sekhar. Pp. 149–168. (Ku Lumpur: Rubber Research Institute of Malaya, 1953.) [91

Fiskeridirektoratets Skrifter. Reports on Norwegian Fishery an Marine Investigations. Vol. 10, No. 4: The Haddock in Norwegia Waters. 1: Vertebrae Counts and Brood Strength Variations o Young Fish. By Gunnar Selmer Saetersdal. Pp. 14. Vol. 10, No. 8 Beskatningen av skreibestanden. Hva merkeforsøk i Lofoten viser Foreløpig rapport. By Gunnar Dannevig. Pp. 37. Vol. 10, No. 9 The Haddock in Norwegian Waters. 2: Methods in Age and Growt Investigations. By Gunnar Selmer Saetersdal. Pp. 46+3 plates (Bergen: Director of Fisheries, 1952–1953.) [91

Transactions of the American Philosophical Society. New Serie Vol. 43, Part 3: Studies on Chromosomes and Nuclear Division (1) Fusion of Nucleoli Independent of Chromosomal Homology (2) Spontaneous Aberrations, Homologous and Non-Homologou Union of Fragments. (3) Pairing, Segregation, and Crossing-over (4) Photomicrographs of Living Cells During Meiotic Divisions. By Prof. L. R. Cleveland. Pp. ii+809–869 (8 plates). (Philadelphia American Philosophical Society, 1953.) 1.50 dollars. [91

Annals of the Observatory of Lund. No. 12: Studies on Orbit Determination of Visual Binary Stars in some Extreme Cases. By N. Wieth-Knudsen. Pp. xiv+77. (Lund: The Observatory, 1953.) [91

Companhia de Diamantes de Angola. Servicos Culturais. Publicacoes Culturais No. 17: Subsidios para o Connecimento da Geologia da Lunda. Diamond Deposits in Lunda, Part 1: a Geological Survey made in 1945–46. Pp. 151. Part 2: A Study made in 1945–48 of the Diamondiferous Gravels and Concentrates. Pp. 224. (With a Report on the discovery of a Kimberlite type of igneous rock in the same fields, presented to the International Geological Congress, Nineteenth Session, Alger, 1952.) By Carlos Freire de Andrade. (Lisboa: Companhia de Diamantes de Angola, 1953.) [911

Smithsonian Institution. Bureau of American Ethnology. Bulletin 156: The Iroquois Eagle Dance, an Offshoot of the Calumet Dance. By William N. Fenton. With an Analysis of the Iroquois Eagle Dance and Songs by Gertrude Prokosch Kurath. Pp. vi+324+28 plates. (Washington: Government Printing Office, 1953.) 1.50 dollars. [1111

Proceedings of the United States National Museum. Vol. 103, No. 3311: Two New Naucorid Bugs of the Genus *Ambrysus*. By Ira La Rivers. Pp. 8. No. 3312: Two New Scale-Mite Parasites of Lizards. By R. F. Lawrence. Pp. 9–18. No. 3313: Note on the Biology and Immature Stages of a Cricket Parasite of the Genus *Rhopalosoma*. By Ashley B. Gurney. Pp. 19–34. No. 3314: Photuris Bethaniensis, a New Lampyrid Firefly. By Frank A. McDermott. Pp. 35–38. No. 3315: Distribution, General Bionomics, and Recognition Characters of Two Cockroaches recently established in the United States. By Ashley B. Gurney. Pp. 39–56+1 plate. No. 3316: Biting Midges of the Heleid Genus *Stilobezzia* in North America. By Willis W. Wirth. Pp. 57–86. No. 3317: Beetles of the Oedemerid Genus *Vasaces* Champion. By Ross H. Arnett, Jr. Pp. 87–94. No. 3318: Scarabaeid Beetles of *Bradycinetulus* and closely related Genera in the United States. By O. L. Cartwright. Pp. 95–120+2 plates. No. 3319: The Chrysomelid Beetles of the Genus *Strabala* Chevrolat. By Doris Holmes Blake. Pp. 121–134. No. 3320: American Biting Midges of the Heleid Genus *Monohelea*. By Willis W. Wirth. Pp. 135–154. No. 3321: A Review of the Beetle Family Cephaloidae. By Ross H. Arnett, Jr. Pp. 155–162+1 plate. (Washington: Government Printing Office, 1953.) [1111

Polska Akademia Umiejetnosci. Prace Rolniczo-Leśne. Nr. 63: Wydajność traków Płonowych. By Tadeusz Orlicz. (Summary in English and Russian.) Pp. 102. 18 zlotys. Nr. 64: Badania nad trzoda chlewna w województwie Olsztyńskim ze szczególnym uwzględnieniem świń o cechach prymitywnych. By Stefan Alexandrowicz. (Summary in English and Russian.) Pp. ii+37+9 plates. 10 zlotys. Nr. 65: Badania nad przejawami rui i ciąży u królic. By Jerzy Szuman. (Summary in English and Russian.) Pp. ii+60. 13 zlotys. Nr. 66: Studia nad budowa warstwy aleuronowej u odmian jęczmienia uprawnego *Hordeum sativum* Jess. By Julian Sawicki. (Summary in English and Russian.) Pp. ii+60+2 plates. 13 zlotys. No. 67: Rozwinięcie teorii ekologicznego wypełnienia przestrzeni i zastosowanie jej w hodowli lasu. By Kazimierz Suchecki. (Summary in French and Russian.) Pp. 98. 16 zlotys. (Krakow: Polska Akademia Umiejetnosci, 1952 and 1953.) [1111

Polska Akademia Umiejetnosci. Prace Rolniczo-Leśne. Nr. 68: Wpływ czynników klimatycznych na przyrost dębu szypułkowego (*Quercus robur* L.) oraz sosny zwyczajnej (*Pinus silvestris* L.). Proba analizy zagadnienia. By K. Ermich. (Summary in English and Russian.) Pp. 62. 12 zlotys. Nr. 69: Doświadczenia ze zwalczaniem chwastów polowych przy pomocy preparatów chemicznych Cz. I. Studium metodyczne. By B. Świętochowski i J. Dzieżyc. (Summary in English and Russian.) Nr. 70: Doświadczenia ze zwalczaniem chwastów polowych przy pomocy preparatów chemicznych. Cz. II. Doświadczenia polowe. By B. Świętochowski, W. Grzegorzyk, i. St. Jelinowski. (Summary in English and Russian.) Pp. ii+38. 10 zlotys. Nr. 71: O określaniu wilgotności drewna przy pomocy pomiarów elektrycznych i o nowym aparacie do mierzenia wilgotności. By M. Jaszewski. (Summary in English and Russian.) Pp. ii+32. n.p. (Krakow: Polska Akademia Umiejetnosci, 1952 and 1953.) [1111

bellan Modular Functions, *review* by Prof. K. Mahler, 323
bellane Modulari : Funzioni (Fabio Conforto), Vol. 1, Preliminari e parte gruppale, geometria simplettica, *review* by Prof. K. Mahler, 323
berg, Dr. B. : Chemical Structure in relation to Plant Growth-Regulating Activity, 710
bhyankar, K. D. (Das, Dr. A. K., and) : Difference of Temperature between Pole and Equator of the Sun, 496
bnormal Embryonic Development of *Drosophila* induced by Ultrasonic Treatment (G. G. Selman and S. J. Counce), 503
bnormal Properties of Helium-4. Classical Considerations on the (S. F. B. Tyabji), 849
boriginals (Australian) : Absence of the Sickle Cell Trait in Seventy-two (W. R. Horsfall and Dr. H. Lehmann), 638
borigines (Australian). High Rh Frequency in the Blood of (R. T. Simmons, Dr. J. J. Graydon and J. B. Birdsell), 500
braham, Dr. E. P. : Adaptation in Micro-organisms, 236
braham, Dr. E. P. (Newton, G. G. F., and) : Isolation of Penicillaminic Acid and D-α-Aminoadipic Acid from Cephalosporin *N*, 395
brahamson, Edwin W. (Linschitz, Dr. Henry, and) : Kinetics of Porphyrin-catalysed Chemiluminescent Decomposition of Peroxides, and the Mechanism of Photosensitized Oxidation, 909
bsence of 'Incomplete' Virus Production in certain Influenza Strains (Dr. S. Fazekas de St. Groth and Miss Doris M. Graham), 1193
bsence of a Landing Effect in *Drosophila subobscura* (Dr. Alex Comfort), 83
bsence of the Sickle Cell Trait in Seventy-two Australian Aboriginals (W. R. Horsfall and Dr. H. Lehmann), 638
bsorption (X-ray) : A Comparison between the, and Optical Interference Methods for the Mass Determination of Biological Structures (Dr. H. G. Davies, Prof. A. Engstrom and Dr. B. Lindstrom), 1041
bsorption of Tocopherol : Effect of Tri-ortho-cresyl Phosphate on the (D. K. Myers and H. E. W. Mulder), 773
bsorption Band at 1,550 cm.$^{-1}$ in Proteins : Origin of the (H. Lenormant and E. R. Blout), 770
bsorption Spectra. Ultra-Violet, and Flow Birefringence of Bovine Cervical Secretions (F. A. Glover), 255
bsorption Spectra of their Ions : Identification of Flavones by the Ultra-Violet (G. H. Mansfield, Dr. T. Swain and C. G. Nordström), 23
bsorption Spectrum of Asparagine : Contribution of the Ultra-Violet, to the Problem of its Structure (Leo J. Saidel), 955
bstracting : International Scientific, 991
buse of Reason : The Counter-Revolution of Science—Studies on the (Prof. F. A. Hayek), 367
cademic Freedom in 1953 : American, 1135
cademic Freedom in a Democracy, 641
cademic Institutions. Aeronautical Research in, 569
cademic Mobility in the British Commonwealth (Sir Charles Morris), 271
cademic Responsibility and Freedom : Professional and, 597
canthocephalan (Larval) : Intersexuality in *Asellus aquaticus* L. parasitized by a (W. R. Munro), 313
cceleration of Flowering in partially Vernalized Grain of Petkus Winter Rye by subsequent Treatment at High Temperature (D. J. C. Friend and Prof. F. G. Gregory), 667
ccelerator (Linear) : Effect of Anomalous Attenuation in a (C. W. Miller and G. Saxon), 463
cetate in Experimental Diabetes : Utilization of (Prof. E. Ciaranfi and A. Fonnesu), 961
cetocarmine as a Nuclear Stain in Rhodophyceae (C. S. Prakasa Rao), 1197
cetylcholine in Blowflies (Dr. S. E. Lewis), 1004
cetylene from Organic Material : Radiocarbon Dating—Large-scale Preparation of (Dr. H. Barker), 631
cetylene-filled Counter for Natural Radiocarbon : Use of an (Dr. A. R. Crathorn), 632
cid : An Unknown, from Brain Extracts Chromatographed on Silica Gel (P. Friedberg, L. M. Marshall and L. H. Newman), 1191
cid Magma : Basic Magma chilled against (Prof. L. R. Wager and Sir Edward Bailey), 68 ; (Dr. Doris L. Reynolds), 69
cid Metabolism in Higher Plants : Zymasis and (Dr. S. L. Ranson), 252
ckman, R. G. : Awarded an Overseas Scholarship for 1953 by the Royal Commission for the Exhibition of 1851, 17
coustic Design of Auditoria (P. H. Parkin and W. A. Allen), 98
coustics : Engineering Aspects of, *review* by Dr. E. G. Richardson, 645
coustics, International Committee of : International Electro-Acoustics Congress, 189, *corrigendum*, 384
ction of Adrenaline on Blood Pressure : Effect of Rauwolscine on the (J. N. Mukherjee), 867
ction of Beryllium on Alkaline Phosphatase : Mode of (Th. A. Veerkamp and G. Smits), 589
ction of Insecticides on a Stem Borer of Oats—the Frit Fly (P. T. Walker), 916
Activation of Fumaric Hydrogenase by Ferrous Ions (K. Harrison), 509
'Actively Acquired Tolerance' of Foreign Cells (Dr. R. E. Billingham, L. Brent and Prof. P. B. Medawar), 603
Activity : Rate of, as a Function of Intertidal Height within Populations of some Littoral Molluscs (Earl Segal, K. Pampapathi Rao and Thomas W. James), 1108
Activity of the Incretory Centres of *Locustana pardalina* during Embryogenesis—Function of the Prothoracic Glands (Dr. Bryn M. Jones), 551
Activity of Nitrogen Mustard : Influence of Cysteinamine, Methylamine and Cortisone on the Toxicity and (Dr. O. Peczenik), 454, *erratum*, 942
Acton Society Trust : Nationalized Industries Series 12, Relations with the Public, 151
  Report on Management under Nationalisation, Studies in Decentralisation, 694
Acton Society Trust and the York Civic Trust : Discussion on Empirical Research in Industry, 897
Adams, C. E. Inhibition of Superovulation in the Rabbit, 82
Adams, E. G., and Simmons, N. T. : Influence of some Impurities, notably Potassium, upon the Reactivity of Iodine Pentoxide towards Carbon Monoxide, 1104
Adams, G. A. : Elected a Fellow of the Royal Society of Canada, 1176
Adams, G. A., and Bishop, C. T.. Polysaccharides associated with Alpha-Cellulose, 28
Adamson, Dr. D. W. : Appointed research director of the Wellcome Foundation, Ltd., and director of the Wellcome Research Laboratories, 526, 654 ; work of, 654
Adamson, G. T. : Physiology of Athletic Training, 935
Adaptation in Micro-organisms (Society for General Microbiology Symposium on), 235
Adcock, M. D. : High-Frequency Electrical Measurements, 54
Addingham Gold Medal for 1952 of the Wm. Hoffman Wood Trust awarded to Dr. Harold King, 840
Adenine into Adenosine Monophosphate : Mechanism of the Incorporation of (Murray Saffran and Eduardo Scarano), 949 ; A New Phosphokinase, 5-Phosphoribokinase (Eduardo Scarano), 951
Adenosine Diphosphate. Direct Deamination of, by Washed Myofibrils (H. L. Webster), 453
Adenosine Monophosphate : Mechanism of the Incorporation of Adenine into (Murray Saffran and Eduardo Scarano), 949 ; A New Phosphokinase, 5-Phosphoribokinase (Eduardo Scarano), 951
Adenosine Triphosphate. Effect of Pyrophosphate on the Shortening of Muscle-Fibre Models in presence of (J. R. Bendall), 586
'Adenosine Triphosphate-Creatine Transphosphorylase' as Relaxing Factor of Muscle (Dr. L. Lorand), 1181
Adenylic Acids *a* and *b* : Structure of (D. M. Brown, G. D. Fasman, D. I. Magrath, Prof. A. R. Todd, W. Cochran and M. M. Woolfson), 1184
Adkins, B. : Analysers and Computers for Electrical Systems, 614
Administrative Studies in Britain : Survey of (British Institute of Management), 795
Adrenal Cortex of the Rat : Effect of 2,2-*bis*(Parachlorophenyl)-1,1-Dichloroethane (DDD) on the (H. B. Stoner), 1044
  Changes in the Vascular and Lipoid Pattern of the, following Hypophysectomy (J. D. Lever, Dr. D. B. Cater and M. P. Stack-Dunne), 33
Adrenal Steroid A New, 1116
Adrenaline on Blood Pressure : Effect of Rauwolscine on the Action of (J. N. Mukherjee), 867
Adrenaline, Noradrenaline and Hydroxytyramine in Extracts from Insects (Dr. Eric Ostlund), 1042
Adrenergic Amines of Blood Effect of Insulin on the (Dr. H. Weil-Malherbe), 396
Adrenocorticotropic Hormone : Influence of Hypophysectomy and of, on a Mammalian Adaptive Enzyme System (Dr. Irving I. Geschwind and Prof. Choh Hao Li), 732
  Non-identity of Intermedin and (Prof. A. O. M. Stoppani, P. F. Pieroni and A. Murray), 547
Adrian, Dr. E. D. : Elected president of the British Association for the Advancement of Science for 1954, 482
  The Growth of Natural Knowledge (Anniversary Address to the Royal Society), 1023
  At the XIX International Physiological Congress, Montreal, 1071
  Honorary doctorate in medicine of the University of Montreal conferred on, 1074
  Elected president of the Royal Society, 1131
Adsorbent : Antibody Chromatography on an Immunologically Specific (L. S. Lerman), 635
Adsorption : The Dynamical Character of (Dr. J. H. de Boer), *review* by Prof. R. M. Barrer, 828
  Fibrinolysis by (Dr. George R. Fearnley), 544
Adsorption Method : Application of a New, in the Study of Flow of Fluids (S. Končar-Djurdjević), 858
Aerobic Spore-forming Bacteria : Crystalline Inclusions in (Dr. C. L. Hannay), 1004
Aerobiology : Arctic (S. M. Pady and L. Kapica), 525
Aerodynamics : High-Speed (W. F. Hilton), *review*, 600
  High-Speed (Prof. Harold W. Sibert), *review*, 600
  Supersonic (Edward R. C. Miles), *review*, 600
Aerodynamics at the National Physical Laboratory, 706
Aerodynamics of High Speed—Facsimiles of Nineteen Fundamental Studies as they were Originally Reported in the Scientific Journals (with a Bibliography compiled by Prof. George F. Carrier), *review*, 600
Aeronautical Conference : Fourth Anglo-American, 146
Aeronautical Research in Academic Institutions, 569

Aeronautical Society, Royal : Medal Awards, 381
  Acceptance of honorary fellowship by H.R.H. the Duke of Edinburgh, 571
  Election of Sir Geoffrey de Havilland, Sir Arthur Gouge and Lord Hives as honorary fellows, 571
  Annual Juvenile Lecture, 1030
Aeronautics : English Electric Research Fellowship in, awarded to R. G. Anderson, 280
Aeronautics Research : Documentation in, 941
Aeroplane Observations of Homing Pigeons (Donald Griffin), 192
Aerosol (Coarse) : Deposition of a, released from a Low-flying Aircraft (D. Yeo and B. W. Thompson), 168
Afferent Fibres (Vagal) : Impulses in, from Stretch Receptors in the Stomach and their Role in the Peripheral Mechanism of Hunger (Dr. A. S. Paintal), 1194
'Affinity' in Maize (Prof. D. G. Catcheside), 112 , (Dr. Donald Michie), 113 ; (Mrs. M. E. Wallace), 113
Africa : Pre-Columbian Maize in (Dr. M. D. W. Jeffreys), 965
  Selection of the Oil Palm (*Elaeis guineensis*) in (A. Devuyst), 685
Africa South of the Sahara, Scientific Council for : Publication No. 3, Directory of Scientific and Technical Libraries in Africa South of the Sahara, 233
Africa (Central) : University Education in, 1
Africa (Central), Commission on Higher Education for Africans in : Report of the, 1
Africa (East) : Birds of, *review* by Sir Landsborough Thomson, 92
  Fertilizer Responses in (Dr. D. W. Duthie), 564
  New Fish Culture Methods for *Tilapia* in (J. M. Brown and Dr. Vernon D. van Someren), 330
Africa (East) High Commission : Appointment of W. Wilkinson and R. M. C. Williams as scientific officers, 571
  Appointment of C. M. Taylor as meteorologist, East African Meteorological Department, 753
  Appointment of C. A. C. Mims as medical research officer, Grade 3, 1030
  Appointment of B. D. Rennison as zoologist, East African Tsetse and Trypanosomiasis Research and Reclamation Organization, 1030
  Appointment of D. G. Cochrane as scientific officer, 1030
Africa (Eastern and North Eastern) : Birds of (C. W. Mackworth-Praed and Capt. C. H. B. Grant), *review* by Sir Landsborough Thomson, 92
Africa (South) : A New Fossil Man from (Dr. J. C. Trevor), 652
Africa (West) Inter-Territorial Research : Appointment of T. A. M. Nash as deputy director, 234
African Botany : International Co-operation in (J. P. M. Brenan), 987
African Inland Waters: Sulphates in (T. Eden), 595; (W. A. Macfadyen), 595
African Migratory Locust in the Solitary Phase and the Dynamics of its Outbreaks : Possibility of Movements of the (J. T. Davey), 720
African (East) Agriculture and Forestry Research Organization : Report for 1952, 984
African (East) Industrial Research Board : Annual Report for 1952, 334
African (East) Meteorological Department : Appointment of C. M. Taylor as meteorologist, 753
African (East) Statistical Department : Appointment of L. U. Clarke as assistant director, 60
African (East) Tsetse and Trypanosomiasis Research and Reclamation Organization : Appointment of B. D. Rennison as zoologist, 1030
African (South) Clawed Toad (*Xenopus laevis*) : Budding of Erythrocytes in the, after Splenectomy (Marcus Jacobson), 1107
Africans in Central Africa, Commission on Higher Education for : Report of the, 1
Agar, Prof. W. E. : A Contribution to the Theory of the Living Organism, second edition, *review*, 223
Age of Science : Literature for an (Prof. Hyman Levy and Helen Spalding), *review* by W. L. Sumner, 49
Agglutination of Red Cells by *Cl. welchii* (E. N. Dafaalla and Dr. M. A. Soltys), 38
Agglutinins (Plant) : Some Interrelationships of the Erythrocytes of various Species with (Lieut.-Colonel G. W. G. Bird), 401
B Agglutinogen in the Erythrocytes: A Rhesus Monkey with (E. C. Büchi), 873
Agreement between Pairs of Time Series : A Suggested Alternative to the Correlation Coefficient for testing the Significance of, and its Application to Geological Data (T. P. Burnaby), 210
Agricultural Botany, National Institute of, Cambridge : *Journal* of the, Vol. 6, 570
  Crop Conference, 797
Agricultural Contractors Association, British, and others : National Weed Control Conference, 442
Agricultural Departments of Colonial Territories : Technical officers in (Secretary of State for the Colonies), 187
Agricultural History Society, British (Association of Agriculture and the) : Conference on Regional History, 985
Agricultural Improvement Council : Reconstitution of the, 278
Agricultural Representatives in the United States : United Kingdom, 654
Agricultural Research, 1953 (Lord Rothschild), 273
Agricultural Research Council : Report No. 13, Aureomycin and Penicillin in Pig Food, 382
  Appointment of Dr. R. Scarisbrick as a scientific assistant to the Secretary, 983
  Promotion of Dr. E. E. Cheesman to the grade of deputy chief scientific officer, 983
Agricultural Research Council, and others : National Weed Control Conference, 442
Agricultural Research Institute : A New—Glasshouse Crops, Mushrooms and Outdoor Flowers and Shrubs (Dr. E. E. Cheesman), 140
Agricultural Research Institute : The Oldest (Dr. W. Lane-Petter), 234
Agricultural Research Service, 89
Agricultural Sanitation in Asia, *review* by Dr. Joseph Needham, 826
Agricultural Service, Federation of Malaya : Appointment of G. Youatt as chemist, 1030
Agricultural Subjects : Postgraduate Scholarships in (Department of Agriculture for Scotland Awards), 840
Agricultural, Forestry and Fishery Products in the United Kingdom and their Utilization : A Survey of (Development Commission), 574
Agriculture : Applications of 'Animal Physiology' to (Dr. John Hammond), 437
  The State and (Sir James Scott Watson), 942
  Use of Antibiotics in, 382
Agriculture in China : Health and (James Cameron Scott), *review* by D Joseph Needham, 826
Agriculture at Leeds, 278
Agriculture, Association of, and the British Agricultural History Society Conference on Regional History, 985
Agriculture, Association of, and the Joint Biology Committee : Conferen on Field Studies in Urban Areas, 571, 1032
Agriculture, Department of, Federation of Malaya : Appointment of L. H. Larter as senior botanist, 1030
Agriculture, Department of, Nigeria : Appointment of D. R. Williams animal geneticist, 1030
Agriculture for Scotland, Department of : Award of Postgraduate Schol ships in Agricultural Subjects, 840
  Appointment of Alexander Paton as technical development offic 1085
Agriculture and Fisheries, Minister of, and the Secretary of State for Sc land : Appointment of a Myxomatosis Advisory Committee, 840
Agriculture and Fisheries, Ministry of : Bulletin No. 30, Rats and Mice the Farm, eighth edition, 335
  New Fisheries Laboratory at Burnham-on-Crouch, 790
Agriculture and Fisheries, Ministry of, and others : National Weed Cont Conference, 442
Agriculture and Science, Department of, Barbados : Appointment W. R. V. Lort as cultivation officer, 753
Agronomy : Soil Physics in, *review* by Dr. H. L. Penman, 48
Ahlers, N. H. E., and Freedman, H. P. : A Double-Beam System for Infr Red Spectrometers employing Rotating Twin Cells, 260
Ahrens, Dr. L. H. : A Fundamental Law of Geochemistry, 1148
Ainsworth, Dr. G. C. : Organic Manures and Fertilizers, 11
Air at Low Pressures : Velocity of Sound in (D. E. Caro and Prof. L. Martin), 363
Air Force, Royal : Flights to assist the British North Greenland Expeditio 101
Air Force Cambridge Research Center (Electronic Research Directorat U.S.A., and others . Symposium on Microwave Optics, 615
Air Ministry (Meteorological Office) : Geophysical Memoirs No. 8 Temperature and Humidity Gradients in the First 100 m. over Sout East England (A. C. Best, E. Knighting, R. H. Pedlow and K. Sto month), 193
Air Motion in the Upper Atmosphere (Dr. R. S. Scorer), 138
Air Pollution (Appointment of a Committee on), 231
Aircraft : The Principles of the Control and Stability of (Prof. W. J. Du can), *review* by Prof. G. Temple, 515
  Some Recent Developments in the Use of, against Flying Locust Swarm (Dr. R. C. Rainey and H. J. Sayer), 224
Aircraft (Low-flying) : Deposition of a Coarse Aerosol released from (D. Yeo and B. W. Thompson), 168
Air-dry Sodium Thymonucleate : Structure of (Dr. U. W. Arndt and D D. P. Riley), 803
Aitchison, Dr. Leslie : Awarded the Institute of Metals (Platinum) Med for 1954, 1173
Aitken, K. L., and others : A Comparison of Lead Isotope Analysis Tec niques, 860
Aitken, Dr. R. S. : Appointment as vice-chancellor of the University Birmingham, 1170 ; work of, 1170
Ajzenberg, F. : Medium-Energy Nuclear Physics, 527
Akimoto, S., and others : Origin of Reverse Thermo-remanent Magnetis of Igneous Rocks, 630
Alaska : High-Altitude Research Laboratory in, 143
Albert, Prof. Adrien : Avidity of Terramycin and Aureomycin for Metal Cations, 201
Albert, Prof. Adrien, and Wood, Dr. H. C. S. : Isoxanthopterin, 118
Albumin, an Unsuspected Physiological Activity (M. W. Blewett, Sir Al Drury and M. Mackay), 79
Alcohols : Photosensitized Oxidation of (J. L. Bolland and H. R. Cooper 413
Aldehyde-Fuchsin : Demonstration of Keratin with (Prof. H. R. Scot 674
Aldehydes and Ketones : Chromatographic Separation using Chemical Treated Paper of, on the Basis of their Reactivity (Dr. A. G. New combe and Dr. S. G. Reid), 455
Alder, Berni J. (Harris, Frank E., and) : Restricted Rotation in Polar Gas near the Critical Point, 774
Aldridge, Dr. W. N. : Anticholinesterases, 842
  Organo-Phosphorus Insecticides, 945
Aleurone Layer : The B-Vitamins in Wheat—the Unique (Dr. J. J. Hinton, F. G. Peers and Dr. B. Shaw), 993
Alexander, K. M., and Vivian, H. E. : Pozzolanic Activity of Ash produc by the Eruption of Mt. Lamington, New Guinea, 1002
Alfrey, Dr. G. F. : Title of University Research Fellow in electron phys in the University of Birmingham conferred on, 709
Algae of Illinois (Lewis Hanford Tiffany and Max Edwin Britton), *review* b Prof. F. E. Fritsch, 268
Algal Chloroplast Fragments : Photochemical Oxygen Production fro Isolated (Dr. Thomas Punnett and Dr. Akinyele Fabiyi), 947
Algebra : On the Metamathematics of (Prof. Abraham Robinson), *revie* 137
Alim, Dr. K. A. : Effect of Two Systems of Management on Milk Yield a Body Temperature of Dairy Cattle, 1195
Alister Hardy : Fisheries Research Vessel, of the Fisheries Research Un University of Hong Kong, 1170
Alkaline Earth Uranates of the R_2MX_4 Type (E. G. Steward and W. Runciman), 75
Alkaline Phosphatase : Mode of Action of Beryllium on (Th. A. Veerkam and G. Smits), 589
Alkaline Phosphatase Activity : Extremely High, in the Vaginal Mucus the Cow (Dr. G. A. van Klinkenberg), 397
Alkaloids of Solanaceae : Biogenesis of (Sir Robert Robinson), 344, erratu 384
Allard, L. S. : Recent Research in Electron Optics, 61
Allen, A. D. : Hydrolysis of Organic Nitrites, 301
Allen, Dr. Clifford : The Psychiatry of Twins, *review*, 739
  A Truant from the Psychoanalytical School, *review*, 827
Allen, Prof. C. W. : The Framework of Astronomy, 490
Allen, Miss Elsa G. . Request for information of the life and work of Jo Abbot, 942

llen, E. M. (Endicott, K. M., and) : Medical Research in the United States, 1172
llen, H. Norman G. : Re-elected chairman of Council of the British Internal Combustion Engine Research Association, 280
llen, K. Radway : A Method for computing the Optimum Size-Limit for a Fishery, 210
llen, T. C., and others : Enzymatic and Chemical Oxidation of Dimethylphosphoramides to Biologically Active Dimethylphosphoramide Oxides, 243
llen, W. A. (Parkin, P. H., and) : Acoustic Design of Auditoria, 98
llen, Dr. W. D. : Progress in Nuclear Science, *review*, 222
llnutt, R. B : Appointed deputy director of agriculture, Western Region, Nigeria, 753
lloy (Precipitation-hardened) Creep Curve for a (G. C. E. Olds), 999
lloys (Non-Ferrous Metals and) : Equipment for the Thermal Treatment of (Institute of Metals), *review* by Prof. F. C. Thompson, 1067
lsop, R. T. : Appointed a Research Fellow in industrial metallurgy at the University of Birmingham, 1084
lsopp, A. : Controlled Leaf Morphogenesis, 612
lmond, Mary : Velocity of δ Aquarid Meteors, 751
lmond, Mary, and others : Radio Echo Observations of the Daytime Meteor Streams in 1952, 751
lper, Tikvah : Effects of Commercial and Radiation-produced Hydrogen Peroxide, 957
lpert, D. : Ionization Phenomena in Gases, 799
-Particle and Conversion-Electron from the Decay of Iodium : Angular Correlation of (Dr. R. R. Roy and Miss M. L. Goes), 360
lpine Club (Royal Geographical Society and the) : Lectures by members of the Everest Expedition, 146
lpine Meteorology : Third International Congress of, 840
lternating-Current Energy Losses in Iron Laminations at Magnetic Saturation (Dr. F. Brailsford and C. G. Bradshaw), 35
Alternative Genetic Pathways : A Relationship between Dominance, Phenotypic Stability and Variability, and a Theory of (Dr. D. Lewis), 1136
Alternative Host (*Leersia hexandra* Sw.) of *Helminthosporium oryzae* Breda de Haan : Occurrence in Nature of an (Dr S. B. Chattopadhyay and N. K. Chakraborti), 550
Altitudes (High) : Biogeographical Research at—Journey to the Gughé Highlands (Southern Ethiopia), 1948–49—(Dr. Hugh Scott), 388
Altman, Prof. K. L., and Miller, Gerald A Disturbance of Tryptophan Metabolism in Congenital Hypoplastic Anaemia, 868
Altman, Prof. K. L., and others : Urinary Excretion of Acid and Neutral Deoxyribonuclease by Rats under Normal and Post-Irradiation Conditions, 867
Aluminium : Gas Content and Electrolytic Etching Behaviour of (Dr. F. J. Burger and Dr. V. F. G. Tull), 729
Aluminium-25 and Nitrogen-13 : Half-value Periods for the Decay of Aluminium-26 (J. L. W. Churchill, W. M. Jones and S. E. Hunt), 460
Aluminium-26, Aluminium-25 and Nitrogen-13 : Half-value Periods for the Decay of (J. L. W. Churchill, W. M. Jones and S. E. Hunt), 460
Aluminium Laboratories, Ltd. : Extensions to the Banbury Premises, 16
Aluminium Tri-Soaps : Preparation of (Dr. R. C. Mehrotra), 74
Alumni Cantabrigienses (compiled by Dr. J. A. Venn), Part 2, From 1752 to 1900, Vol. 5, Pace–Spyers, *review* by Prof. F. J. M. Stratton, 825
Alvarenga Prize for 1953 awarded by the College of Physicians of Philadelphia to Dr. F. D. Moore, 146
Alway, G. G. Utilization of Digital Computing Machines in Engineering and Industry, 650
Ambache, N. : Action of Drugs at Autonomic Ganglia, 1075
Ambrose, E. J., and Easty, G. C. : Detection of Antigen–Antibody Interactions by an Interferometric Method, 811
Amelinckx, S., and Votava, E. : Relation between Frank Spirals and Spiral Pits in Crystals, 538
Amer, Santos : Awarded a Ramsay Memorial Fellowship for research in Chemistry, 103
America (Eastern North) : Two Cytological Forms of *Polypodium virginianum* in (Prof. I. Manton and M. Shivas), 410
American Academic Freedom in 1953, 1135
American Aid for Industrial and Technological Research in Britain, 15
American Aid for Scientific and Industrial Research in Great Britain, 528
American Association for the Advancement of Science . Meeting in Boston, 894
American Association of Physics Teachers : Annual Meeting, 338
  Oersted Medal presented to Prof. R. M. Sutton, 338
  Eleventh Richtmyer Memorial Lecture (Prof. E. M. Purcell), 338
  Election of Officers for 1953, 339
  Discussion on Physics beyond General Physics for Non-Physics Majors, 339
  Discussion on Undergraduate Laboratory Teaching, 339
  Honorary membership conferred on Prof. R. Pohl and Prof. J. H. Keenan, 339
  Citations awarded to H. K. Hughes, E. C. Kemble, T. H. Osgood, R. R. Palmer, K. Lark-Horovitz and M. W. White, 339
American Bacteriologists, Society of : Commercial Solvents Award in Antibiotics awarded to Dr. Ibert C. Wells, Dr Edwin E. Hays, Dr. E. A. Doisy and Dr. William L. Gaby, 382
American Chemical Society (Division of Physical and Inorganic Chemistry and the Eastern New York Section) in conjunction with the Division of Solid State Physics of the American Physical Society : Symposium on Impurity Phenomena, 385
American Higher Education : Finance of, *review* by Sir Hector Hetherington, 470
American Histochemical Society : *Journal of Histochemistry and Cytochemistry*, 232
American Institute of Electrical Engineers, and others : Conference on High-Frequency Electrical Measurements, 52
American Meteorological Society : Election of honorary members, 1168
American Meteorological Society, and others : Meteorological Conference at Toronto, 103, 1166
American Philosophical Society : Year Book for 1952, 529
American Physical Society : Annual Meeting, 338
  Retiring Presidential Address (Prof. J. H. Van Vleck), 338
  O. E. Buckley Solid-State Physics Prize presented to Dr. W. Shockley, 338
  Election of Officers for 1953, 338
American Physical Society (Division of Solid State Physics) and the Division of Physical and Inorganic Chemistry and the Eastern New York Section of the American Chemical Society : Symposium on Impurity Phenomena, 385
American Psychology History of (A. A. Roback), *review* by Prof John Cohen, 599
American Scientists Origins of, a Study made under the direction of a Committee of the Faculty of Wesleyan University (R. H. Knapp and H. B. Goodrich), *review* by Sir Arthur Trueman, 373
  Recruitment of, *review* by Sir Arthur Trueman, 373
American Slipper Limpet (*Crepidula fornicata*) in Milford Haven (Dr. H. A. Cole and R. H Baird), 687
American Society of Civil Engineers (Engineering Mechanics Division), and others : Symposium on Plasticity, 17
American Society of European Chemists : Medal awarded to Prof W. T. Astbury for his contribution to international scientific relations, 797
American Society for the Study of Sterility . Prize for an Essay on Infertility and Sterility, 656
American Universities, Association of The Rights and Responsibilities of Universities and their Faculties, 217, 598, 641
Ames, Oakes, and Correll, Donovan Stewart Orchids of Guatemala, 144
Amethyst : Magnetic Study of (M. Leela), 464
Amines (Adrenergic) Effect of Insulin on the, of Blood (Dr. H. Weil-Malherbe), 396
Amines (Tertiary) Compounds of, with Nitrosyl Chloride and with Dinitrogen Tetroxide (Dr Alan E. Comyns), 491
Amino-Acids : A Chromatographic Colour Reagent for a Group of (Dr G. Curzon and J Giltrow), 356
  Influence of Cations on the Ninhydrin Reaction for the Determination of (Dr. Hanan Meyer and Emanuel Riklis), 543
  Qualitative Organic Microanalysis based on Physical Constants—Identification of (Dr. A. Lacourt, G. Sommereyns, C. Francotte and N. Delande), 906
Amino-Acids in Cerebrospinal Fluid : Paper Chromatography of (A. P Prior and T. P. Whitehead), 358
Amino-Acids and the Growth of Isolated Oat Embryos (G. P Harris), 1003
Amino-Acids in Phloem Sap and their Excretion by Aphids (T. E. Mittler), 207
Amino-Acids present in Purified Prothrombin . Identification of, by Circular Paper Chromatography (Gauranga Ray, N. C. Ganguli and S. C. Roy), 809
Amino-Acids and Proteins : A Colorimetric Method, based on Metallic Complex Formation, for the Detection of Aureomycin in presence of (Dr. A. E. Oxford), 395
Amino-Groups Spectrophotometric Determination of (Miss Dallas Fraser and H. G. Higgins), 459
D-α-Aminoadipic Acid Isolation of Penicillaminic Acid and, from Cephalosporin *N* (G. G. F. Newton and Dr. E. P. Abraham), 395
4-Amino-5-imidazolecarboxamide as a Pentose Derivative . Occurrence of (Joseph S. Gots), 256
Aminolaevulinic Acid and Porphyrin Biosynthesis (Dr. A. Neuberger and J. J. Scott), 1093
δ-Aminolaevulinic Acid : Conversion of, to Porphobilinogen in a Tissue System (Dr. E. I. B. Dresel and Dr. J. E. Falk), 1185
Ammonia Assimilation by *Chlorella* (P. J. Syrett), 984
Amniotic Fluid in the Lamb A Source of—the Naso-Pharyngeal and Buccal Cavities (Dr. S. R. M. Reynolds), 307
Amoeba proteus : Relation between Dye Uptake and Cytoplasmic Streaming in (D. M. Prescott), 593 ; (R. J. Goldacre), 593
Amoebae (Intestinal) Rapid Staining of, on Wet Mounts (C P. Nair), 1051
Amoroso, Prof. E. C. : Physiology of Athletic Training, 935
Amphlett, Dr. C. B. : Use of Fission-Product Radiation, 147
Ampulla of the Isolated Elasmobranch Labyrinth : Effect of Galvanic Polarization on the Impulse Discharge from the Horizontal (Prof. Otto Lowenstein), 549
Amylolysis : The Z-Enzyme in (Prof. R H. Hopkins and Dr. R. Bird), 492 ; (Prof. Stanley Peat and Dr. W. J. Whelan), 494
Anaemia (Congenital Hypoplastic) : A Disturbance of Tryptophan Metabolism in (Prof. K. L Altman and Gerald Miller), 868
Anaemias (Human) Detection of Foetal and Sickle-cell Haemoglobins in (Dr. G. H. Beaven and Dr J. C. White), 1006
Anal Papillae of *Culex* (*culex*) *fatigans* Wiedemann . Observations on the (James G. Halcrow), 1156
Analysers and Computers for Electrical Systems (Vacation School at the Imperial College of Science and Technology), 614
Analysing Flow of Granular Materials such as Sand : Method of (J. Glittus), 364
Analysis Foundations of (Edmund Landau), translated by F. Steinhardt, *review* by Prof. H. T. H. Piaggio, 7
Analysis for Deuterium based on the Photoneutron Effect (Dr. C. P. Haigh), 359
Analysis of Experiment : The Design and (M. H Quenouille), *review*, 785
Analysis of Organic Hydroperoxides in the presence of Hydrogen Peroxide (H. Bruschweiler, G. J. Minkoff and K. C. Salooja), 909
Analysis of Personality, *review* by F. V. S., 5
Analysis and Description in Social Anthropology (Prof. M. Fortes), 434
Analytical Abstracts (Society of Public Analysts and other Analytical Chemists), 984
Analytical Separation of the Methyl Esters of the C_{12}–C_{22} Fatty Acids by Vapour-Phase Chromatography (F. R. Cropper and A Heywood), 1101
Ananthakrishnan, Dr. R. : Geomagnetic Activity and the Sunspot Cycle, 854
Ananthakrishnan, Dr. R., and others : Recording Photoelectric Spectrophotometer at Kodaikanal Observatory, 383
Anatomy and Taxonomy of the Lemurs and Lorises : Comparative, *review* by Prof. S. Zuckerman, 880
Ancient and Medieval Science in Asia, *review* by Dr. Joseph Needham, 1018
Anderson, A. W. : Appointed veterinary officer, Gambia, 571
Anderson, Donald F. : Oil Pollution of the Sea, 1025
Anderson, Dr. D. S. : Supply and Education of Managers for British Industry, 714
Anderson, E. C., and others : Determination of Total Body Radioactivity using Liquid Scintillation Detectors, 521
Anderson, L. J., and Gossard, E. E. : Oceanic Duct and its Effect on Microwave Propagation, 298

Anderson, Dr. Norman G.: Degree of Polymerization of Deoxyribonucleic Acid, 807
Anderson, R. G.: Awarded the English Electric Research Fellowship in Aeronautics, 280
Anderson-Berry Prize for 1953 of the Royal Society of Edinburgh awarded to Dr. John Read, 1085
Andlauer, P.: Biological Rhythms, 944
Andrews, Dr. J. P.: Kumasi College of Technology, Gold Coast, 609
Anet, E. F. L. J., and Reynolds, T. M.: Isolation of *l*-Quinic Acid from the Peach Fruit, 1186
Angles, R. M., and others: Awarded jointly the Westinghouse Brake and Signal Co., Ltd., Prize for 1952–53 by the Institute of Metal Finishing, 656
Anglo-American Aeronautical Conference: Fourth, 146
Anglo-Italian Mixed Commission: Meetings in London, 894
Angular Correlation of α-Particle and Conversion-Electron from the Decay of Ionium (Dr. R. R. Roy and Miss M. L. Goes), 360
Anhydrides (N-Carboxy-α-amino-acid): Kinetics of the Formation of Polypeptides from (D. G. Ballard and Dr. C. H. Bamford), 907
Animal Behaviour, Association for the Study of: Symposium on Rat Behaviour, 498
Animal Behaviour, British Journal of, No. 1, 16
Animal Ecology (W. H. Dowdeswell), *review* by T. H. Hawkins, 973
Animal Hair: Resistant Components of the Cortex of (E. H. Mercer), 164
Animal Husbandry: William McIlrath Fellowship for research and teaching in (Commonwealth Scientific and Industrial Research Organization), 794
'Animal Physiology': Applications of, to Agriculture (Dr. John Hammond), 437
Animal Viruses: Weight Relationships among (Dr. Alfred Polson), 1154
Animal Welfare, Universities Federation for: Summer School, 336
Animal and Vegetable Resources of Great Britain (Dr. Thomas Moore), 574
Animals: Chemotherapy of Man and, *review* by Dr. R. A. Shooter, 644
  Locomotion of, *review* by Dr. L. Harrison Matthews, 698
  Organic Manures and Fertilizers and the Production and Composition of Food for Man and (Section of Comparative Medicine of the Royal Society of Medicine Discussion on), 11
  The Sulphonamides and Antibiotics in Man and (Dr. J. Stewart Lawrence and Prof. John Francis), second edition, *review* by Dr. R. A. Shooter, 644
Animals (Intertidal): Isolation of, by Sea Barriers (Dr. D. J. Crisp and Dr. A. J. Southward), 208
Animals (Lower): A Physiological Approach to the (Dr. J. A. Ramsay), *review* by Dr. J. A. Kitching, 92
Animals (Small): A New Method of measuring Oxygen consumed in the Metabolism of (Prof. V. Capraro), 815
Animals at the Zoological Gardens (Zoological Society of London Course for School Teachers), 708
Animals Move: How (Prof. James Gray), *review* by Dr. L. Harrison Matthews, 698
Annual Review of Biochemistry (edited by J. Murray Luck, Hubert S. Loring and Gordon Mackinney), Vols. 20 and 21, *review* by Prof. F. G. Young, 928
Annual Review of Nuclear Science (edited by James G. Beckerley), Vol. 2, *review* by Dr. W. D. Allen, 222
Anomalous Attenuation: Effect of, in a Linear Accelerator (C. W. Miller and G. Saxon), 463
Anopheles gambiae: Inter-relations between Filarial and Malarial Infections in (Dr. R. C. Muirhead-Thomson), 352
Anopheline Mosquitoes in Nature: A New Method of Estimating the Survival-Rate of (C. C. Draper and G. Davidson), 503
Ant World (Derek Wragge Morley), *review* by T. H. H., 473
Antarctic Exploration: Programme of Australian (Sir Douglas Mawson), 479
Antarctic Today, a Mid-Century Survey by the New Zealand Antarctic Society (edited by Frank A. Simpson), *review* by J. D. M. Blyth, 372
Antarctica: Progress in, *review* by J. D. M. Blyth, 372
Anthropology: Cultural, *review* by Dr. Paul Bohannan, 972
  Studies in, *review* by Prof. Daryll Forde, 1015
Anthropology (Social): Analysis and Description in (Prof. M. Fortes), 434
Anthropology Today (prepared under the chairmanship of A. L. Kroeber), *review* by Prof. Daryll Forde, 1015
Antibacterial Activity of Polymyxin: Reversal of the, by Divalent Cations (B. A. Newton), 160
Antibiotic: Humicolin, a New (P. J. Curtis, H. G. Hemming and E. G. Jeffreys), 187
Antibiotics: Commercial Solvents Award in, awarded to Dr. Ibert C. Wells, Dr. Edwin E. Hays, Dr. E. A. Doisy and Dr. William L. Gaby, 382
  Effect of, on the Growth of the Silkworm, *Bombyx mori* L. (M. R. Venkatachala Murthy and M. Sreenivasaya), 684
Antibiotics, their Production and Use in Industry (Society of Applied Bacteriology Symposium on), 329
Antibiotics in Agriculture: Use of, 382
Antibiotics in Man and Animals: The Sulphonamides and (Dr. J. Stewart Lawrence and Prof. John Francis), second edition, *review* by Dr. R. A. Shooter, 644
Antibody Chromatography on an Immunologically Specific Adsorbent (L. S. Lerman), 635
Anticholinesterases (British Pharmacological Society and the Fine Chemicals Group of the Society of Chemical Industry Symposium on), 841
Anti-Diuretic Substances of the Blood (Prof. H. Croxatto and L. Barnafi), 304
Antifungal Substance from a Strain of *B. subtilis* (Dr. P. Nandi and G. P. Sen), 871
Antigen (Tobacco Mosaic Virus): Radioautographic Study of the Localization of (Dr. F. Gavosto and Mrs. A. Ficq), 406
Antigen–Antibody Interactions: Detection of, by an Interferometric Method (E. J. Ambrose and G. C. Easty), 811
Antigens: Family, or 'Private' Blood Groups and the Sub-Group of A–A_1 (L. Dunsford), 1059
Anti-Reflexion Coatings on Dielectric–Air Interfaces: Thin Metallic Films for (F. H. Smith), 462
Anura: Frequency of Moulting in (Sonya Bouwer, Dr. D. W. Ewer and Clive Shiff), 408
Aphids: Amino-Acids in Phloem Sap and their Excretion by (T. E. Mittler), 207
  Flight Muscle Autolysis and Reproduction in (Bruce Johnson), 813
Apices: Comparative Studies of, 1172
Appelmans, F., and others: Enzymic Content of the Mitochondria Fraction, 1143
Apple Fruits: A New Hydroxy-acid in the Peel of (Dr. A. C. Hulme), 346
Apples and Pears: Chlorogenic Acid and the Enzymic Browning of (C. Weurman and Dr. T. Swain), 678
Appleton, Sir Edward: Science for its own Sake (Presidential Address to the British Association for the Advancement of Science), 424
  Appointed chairman of a Committee to advise the Secretary of State for Scotland on the supply of Mathematics and Science Teachers in Scotland, 730, 839
Appleton, Sir Edward: To (Stanley Dumbell), 482
Applications of Fluid Dynamics: Theory and, *review*, 600
Applications of Photography: Science and (Royal Photographic Society International Conference on), 145, 1121
'Aqualung': Underwater Exploration by, *review* by Dr. A. J. Brook, 370
δ Aquarid Meteors: Velocity of (Mary Almond), 751
Aquatic Larva, suitable for Laboratory Work (Dr. N. E. Hickin), 874
Aqueous Solutions or Dispersions: Quantitative Determination of Ethylene Oxide Products in (Dr. N. Schönfeldt), 820
Arc Transitions on Cathode Surface Conditions: Dependence of Glow to (Dr. H. Edels), 362
Archard, G. D.: Recent Research in Electron Optics, 61
Archard, J. F.: Elastic Deformation and the Contact of Surfaces, 918
Archibald, Sir Robert: *Obituary* by Dr. Robert Kirk, 56
Architectural Science at Sydney, 568
Architecture: Scholarships in Science, Technology and (Massachusetts Institute of Technology), 1030
Arctic Aerobiology (S. M. Pady and L. Kapica), 525
Arctic Institute of North America (McGill University and the): Fellowship and Scholarships for Arctic or Sub-Arctic Research, 1085
Arctic or Sub-Arctic Research: Fellowship and Scholarships for (McGill University and the Arctic Institute of North America), 1085
Arginine and Deoxyribonucleic Acid Content of Erythrocyte Nuclei and Sperms of some Species of Fishes (Dr. R. Vendrely and C. Vendrely), 30
Arkell, Dr. W. J.: Awarded the Leopold von Buch Medal of the German Geological Society, 709
Armament Research Establishment, 1075
Armillaria mellea: Rhizomorph Formation in (S. D. Garrett), 796
Armstrong, D. M. B.: Dyeing and Tanning, 1032
Armstrong, Dr. E. B.: Appointed a lecturer in physics at Queen's University, Belfast, 60
Arndt, Dr. U. W., and Riley, Dr. D. P.: Intra-Helix S—S Linked Structures for Insulin, 245
  Structure of Air-dry Sodium Thymonucleate, 803
Arndt, Dr. U. W. (Riley, Dr. D. P., and): X-Ray Scattering Evidence regarding the Protein–Nucleic Acid Combination in Nucleoproteins, 294
Arnon, Prof. Daniel I., and Wessel, Gunilla: Vanadium as an Essential Element for Green Plants, 1039
Aromatic Compounds: Bond-Orders in (Dr. G. M. Badger and H. A. McKenzie), 458
  Phenylation, Benzoyloxylation and Halogenation of, by Silver Benzoate–Halogen Complexes (Dr. D. Bryce-Smith), 863
  Ultraviolet Spectra of (Dr. Robert A. Friedel and Dr. Milton Orchin), *review* by Dr. E. Clar, 223
Aronoff, Dr. S., and Graf, G. E.: Carbon Dioxide Fixation and Mitotic Poisons, 1043
Arons, A. B., and others: Giant Condensation Nuclei from Bursting Bubbles, 1144
Arrol, Dr. J. W.: Use of Fission-Product Radiation, 149
Artemia salina L.: Intranuclear Proteins of the Oocytes in (N. Fautrez-Firlefyn and Prof. J. Fautrez), 163
Arthur, Dr. D. R.: Awarded a Leverhulme Research Grant for 1953, 17
Arthur, John: Through Movement to Life, *review* by T. H. Hawkins, 7
Arts: Science and the (Prof. R. E. Gibson), 707
Arts, Royal Society of: Bicentenary Essay Competition on Life in A.D. 2000, 985
Aschoff, T.: Biological Rhythms, 943
Ascidian: Discovery of Iron in Tunicin-forming Blood Cells of an (R. Endean), 123
Ascites Carcinoma Cells (Ehrlich): Fixation of Radioactive Colchicine by (A. Back and E. J. Walaszek), 202
Ascomycete from the Upper Carboniferous: A Presumed (Dr. S. A. Hutchinson and Prof. J. Walton), 36
Ascospore Dimorphism (M. J. Mathieson), 144
Asellus aquaticus L. parasitized by a Larval Acanthocephalan: Intersexuality in (W. R. Munro), 313
Ash produced by the Eruption of Mt. Lamington, New Guinea: Pozzolanic Activity of (K. M. Alexander and H. E. Vivian), 1002
Ashbridge, Sir Noel: Made an honorary member of the British Institution of Radio Engineers, 797
Ashby, A. W.: *Obituary* by Dr. C. S. Orwin, 891
Ashby, J. R.: Appointed to the University of London readership in physics at the Imperial College of Science and Technology, 234
Ashby, Prof. Ross: Cybernetics, 648
Ashmore, Dr. P. G.: Explosions in Mixtures of Hydrogen, Chlorine and Nitrogen Trichloride, 449
Ashton, G. C. (Foster, M. C., and): Paper Electrophoresis of Streptomycins, 958
Ashton, Sir Leigh: Elected president of the Museums Association, 107
Asia: Agricultural Sanitation in, *review* by Dr. Joseph Needham, 826
  Ancient and Medieval Science in, *review* by Dr. Joseph Needham, 1018
Asia (South): Bibliography of Scientific Publications of (Unesco South Asia Science Co-operation Office), No. 7, India, Burma and Ceylon, January–June 1952, 234
Aslakson, Comdr. C. L.: High-Frequency Electrical Measurements, 53
Aslib: Residential Conference on Information Service, 18
  Microfilm copies of the Patent Office's Press Mark Indexes, 103
  Register of Specialist Indexers, 143
  Directory of Sources of Specialized Information in Great Britain and Ireland, 613
  Index to Theses accepted for Higher Degrees in the Universities of Great Britain and Ireland, Vol. 1, 985

Asparagine : Contribution of the Ultra-Violet Absorption Spectrum of, to the Problem of its Structure (Leo J. Saidel), 955
Asparagopsis armata Harv. on the Coast of Devon : Occurrence of (Joy Karslake), 874
Aspartate–Glutamate Transaminase in a Red Halophilic Bacterium (J. Robinson and H. Katznelson), 672
Aspergillus : Effect of Molybdenum Deficiency on Nitrate Reductase in Cell-free Extracts of *Neurospora* and (D. J. Donald Nicholas, Alvin Nason and Dr. William D. McElroy), 34
Aspergillus nidulans : Nidulin and 'Ustin', Two Chlorine-containing Metabolic Products of (Dr. F. M. Dean, Prof. A. Robertson, Dr. John C. Roberts and Dr. K. B. Raper), 344
Assay (Biological) : Sequential Sampling in (Elisabeth Bukovics and F. X. Wohlzogen), 1058
  Statistical Method in (Dr. D. J. Finney), *review* by Dr. J. O. Irwin, 925
Assaying : Treatise on Ores and (Lazarus Ercker), translated from the German edition of 1580 by Anneliese Grunhaldt Sisco and Cyril Stanley Smith, *review*, 643
Assaying in the Sixteenth Century : Practice of, *review*, 643
Assays (*in vitro*) : Chromatographic Behaviour of Intermedin as determined by (Robert R. Kohn), 1185
Association pour l'Étude Taxonomique de la Flore d'Afrique Tropicale : Second Plenary Meeting, 987
Astbury, Prof. W. T : Awarded a medal by the American Society of European Chemists for his contribution to international scientific relations, 797
Asterococcus mycoides : Pathway for Glucose Oxidation in (A. W. Rodwell and E. Shirley Rodwell), 254
Astin, Dr. A. V. : High-Frequency Electrical Measurements, 52
Astronomer Royal : Report to the Board of Visitors of the Royal Greenwich Observatory, 1034
Astronomical Observatories of Jai Singh, *review* by Sir Harold Spencer Jones, 645
Astronomy . The Framework of (Prof. C. W. Allen), 490
  Radio (Prof. Bernard Lovell and Dr. J. A. Clegg), *review* by J. A. Ratcliffe, 47
  Statistical (Robert J. Trumpler and Harold F. Weaver), *review* by Prof. W. M. Smart, 1017
Astronomy (Radio-) in the Tropics (Prof. H. E. Huntley), 108
Astrophysics : Precision in, *review* by Prof. W. H. McCrea, 924
Astwood, E. B. Mechanism of Formation of the Thyroid Hormone, 1074
Atherton, Dr. F. A. : Anticholinesterases, 841
Athletic Training : Physiology of (British Association for the Advancement of Science, Section I (Physiology), Symposium on), 934
Athlone Fellowship Scheme for Canadian Engineers (Dr. W. Abbott), 758
Atkins, Dr. (Miss) D. Awarded a Leverhulme Research Fellowship for 1953, 17
Atkins, Dr. W. R. G., and Jenkins, Pamela G. : Reduction in Light accompanying Exceptionally Heavy Rain, 79
Atkinson, R. J. C. : Stonehenge in the Light of Recent Research, 474
Atkinson, V. A. : Awarded a Research Scholarship in Chemistry by British Celanese, Ltd., 442
Atlantic (North) : Oil Pollution Research—Plotting of Currents in the (National Institute of Oceanography), 750
Atlantic (North) Weather Ships, 933
Atmosphere Daily Variation of Amount of Ozone in the (Dr. K. R. Ramanathan and Bh. V. Ramana Murthy), 633
  Seeing through the, *review* by Dr. John W. T. Walsh, 1118
  Vision through the (W. E. Knowles Middleton), *review* by Dr. John W. T. Walsh, 1118
Atmosphere (Lower) : Variation of Humidity with Height in the, 193
Atmosphere (Upper) : Air Motion in the (Dr. R. S. Scorer), 138
  Synoptic Rocket Observations of the (Dr. S. F. Singer), *erratum*, 18
Atmospheric Ozone and the Upper-Air Conditions (Sir Charles Normand), 241
Atmospheric Pollution . Effects of, on Vegetation (British Association for the Advancement of Science, Sections K (Botany) and K^* (Forestry), Discussion on), 659
Atmospherics : Audio-Frequency Spectrum of (Dr. F. W. Chapman and W. D. Matthews), 495
Atomic Energy Course of Lectures on (Atomic Scientists' Association and the University of London Extra-Mural Department), 1084
  Parliamentary Responsibility for, 1083
  Proposals for the International Control of (President Eisenhower), 1129
Atomic Energy in Britain for Electrical Power : Use of, 894
Atomic Energy in Great Britain, 939
Atomic Energy Development, 983
Atomic Energy Project (United Kingdom) : White Paper on the, 939
Atomic Energy Research Establishment, Harwell : Course on Electronic Instruments, 336
  Courses on the Techniques of Using and Handling Radioactive Materials, 656, 1084
  Radioisotope Conference, 986
Atomic Energy Research Establishment (Chemistry Division) : Symposium on the Use of Fission-Product Radiation, 147
Atomic Energy Research Establishment (Physical Chemistry Group) : Symposium on Solutions of Electrolytes in Organic Solvents, 149
Atomic Models . Structure of Insulin as indicated by (Dr. Conmar Robinson), 27
Atomic Nucleus Structure of the (Conference at the University of Birmingham), 426
Atomic Pile : Szilard and Chalmers Effect by Irradiation of Hexavalent Chromium in an (Dr. B. Ottar), 362
Atomic Power Consequences of, *review* by B. L. Goodlet, 369
Atomic Power, an Economic and Social Analysis (Walter Isard and Vincent Whitney), *review* by B. L. Goodlet, 369
Atomic Scientists' Association and the University of London Extra-Mural Department : Lectures on Atomic Energy, 1084
Atoms : Interstitial, in the Layer Structure $ZnMn_3O_7\,3H_2O$ (Chalcophanite), (A. D. Wadsley), 1103, *erratum*, 1173
Atropine Effect of Cholinesterase Inhibitors and, on Active Sodium Transport across Frog Skin (Leonard B. Kirschner), 348
Attenuated Strain of the Myxomatosis Virus recovered from the Field (Dr. R. Mykytowycz), 448
Attenuation (Anomalous) : Effect of, in a Linear Accelerator (C. W. Miller and G. Saxon), 463
Audio-Frequency Spectrum of Atmospherics (Dr. F. W. Chapman and W. D. Matthews), 495
Auditoria : Acoustic Design of (P. H. Parkin and W. A. Allen), 98
Audus, Prof. L. J. : Chemical Structure in relation to Plant Growth-Regulating Activity, 710
  Plant Growth Substances, *review* by Prof. R. L. Wain, 1117
Aughtie, Dr. F. : Title of University Research Fellow in physics in the University of Birmingham conferred on, 709
Augustin, Dr. Rosa : Precipitins to Grass Pollen Proteins, 307
Augustine to Galileo, the History of Science A.D. 400–1650 (A. C. Crombie), *review* by Dr. W. P. D. Wightman, 134
Auld, Lieut.-Colonel S. J. M. : The Petroleum Industry, *review*, 1065
Aureomycin : Avidity of Terramycin and, for Metallic Cations (Prof. Adrien Albert), 201
  Listeria Infection in the Guinea Pig caused by Feeding with (Prof. Paavo Roine, Anne Raitio and Unto Vartiovaara), 767
Aureomycin in presence of Amino-Acids and Proteins A Colorimetric Method, based on Metallic Complex Formation, for the Detection of (Dr. A. E. Oxford), 395
Aureomycin and Penicillin : Use of (Ministry of Health, Statutory Instruments 1172 and 1174), 382
Aureomycin and Penicillin in Pig Food (Agricultural Research Council, Report No. 13), 382
Austin, C. R., and Braden, A. W. H. : Polyspermy in Mammals, 82
Australia . Directory and Catalogue of Micro-organisms maintained in (Commonwealth Scientific and Industrial Research Organization), 484
  Fluorine Tests in, on the Keilor Skull and a Tertiary Marsupial (Edmund D. Gill), 409
  Initial Spread of Myxomatosis in (John LeGay Brereton), 108
  Nemataceae, a Moss Family New to (J. H. Willis), 127
  Science in, 969
Australian Aboriginals : Absence of the Sickle Cell Trait in Seventy-two (W. R. Horsfall and Dr. H. Lehmann), 638
Australian Aborigines . High Rh Frequency in the Blood of (R. T. Simmons, Dr. J. J. Graydon and J. B. Birdsell), 500
Australian Antarctic Exploration : Programme of (Sir Douglas Mawson), 479
Australian Institute of Agricultural Science : Election of Prof. W. L. Waterhouse as an honorary life member, 336
Australian Journal of Biological Sciences : New title of the former *Australian Journal of Scientific Research*, Series B (Biological Sciences), 18
Australian Journal of Botany, 18
Australian Journal of Chemistry, 18
Australian Journal of Physics, 18
Australian Journal of Scientific Research, Series A (Physical Sciences) To be divided into the *Australian Journal of Chemistry* and the *Australian Journal of Physics*, 18
Australian Journal of Scientific Research, Series B (Biological Sciences) Title changed to the *Australian Journal of Biological Sciences*, 18
Australian Journal of Zoology, 18
Australian National University, Canberra : Appointment of L. G. Melville as vice-chancellor, 103
  Appointment of the governing body of University House, 440
Australian Wild Rabbit : Changes in the Mortality-rate due to Myxomatosis in the (Prof. Frank Fenner), 228
Australian and New Zealand Association for the Advancement of Science: Thirtieth Meeting, 571
Australopithecine Milk Canines (Dr. J. Bronowski and W. M. Long), 251
Austria : Mammoth Hunters in, 570
Austrian Wood Research Institute, Vienna (Prof. Josef Kisser), 1120
Auto-Agglutinins : Specificity of Complete Cold (Lieut.-Colonel G. W. G. Bird), 734
Automatic Control : Fundamentals of (G. H. Farrington), *review* by Prof. J. Greig, 91
Automatic Control of Mechanisms and Industrial Processes, *review* by Prof. J. Greig, 91
Automatic Digital Computing Machines : Programme Design for (University of Cambridge Mathematical Laboratory Summer School in), 18
Automatic Grain Counter for Assessing Quantitatively High-Resolution Autoradiographs (Dr. R. A. Dudley and Dr. S. R. Pelc), 992
Autonomic Blocking Agent . A New Type of (Stata Norton and Arthur P. Phillips), 867
Autoradiographic Detection of Sulphur-35 Synthesis by the Mucous Neck Cells of the Rat's Stomach (Prof. Leonard F. Bélanger), 1150
Autoradiographs (High-Resolution) . Automatic Grain Counter for Assessing Quantitatively (Dr. R. A. Dudley and Dr. S. R. Pelc), 992
Autosome Segments of *Ceriagrion coromandelianum* (Odonata) : Heteropycnosis in the (Dr. M. D. L. Srivastava and C. C. Das), 765
Autumn Flush of *Drosophila* (Diptera), (E. B. Basden), 1155
Autumn Spawning Herring : Sperm Storage and Cross-Fertilization of Spring and (J. H. S. Blaxter), 1189
Avian Medullary Bone (T. G. Taylor and Dr. J. H. Moore), 504
Avidity of Terramycin and Aureomycin for Metallic Cations (Prof. Adrien Albert), 201
Avison, A. W. D. : Anticholinesterases, 841
Awad, William L., and others . The Fries Reaction, 1186
Awbery, J. H. . A University Text-Book of Physics, Vol. 3, Heat (being the eleventh edition and a largely rewritten version of Poynting and Thomson's 'Text-Book of Physics,' Vol. 3), *review* by H. L., 1069
Axial Flow in a Vortex (John B. Nuttall), 582
Aynard, C. : At the fourth meeting of the European Association of Exploration Geophysicists, 191

BAAR, Dr. S., and Bull, Dr. J. P. : Salt Interference in Sugar Chromatography of Urine, 414
Bacharach, A. L. : Organo-Phosphorus Insecticides, 946
  Provisioning of Expeditions in the Field, 975
Bacitracin A . Structure of (Dr. J. Porath), 871
Back, A., and Walaszek, E. J. : Fixation of Radioactive Colchicine by Ehrlich Ascites Carcinoma Cells, 202
Bacon, G. E. : Promoted a Senior Principal Scientific Officer in the Scientific Civil Service, 657

B. subtilis : An Antifungal Substance from a Strain of (Dr. P. Nandi and G. P. Sen), 871
  Effect of Citric Acid on the Growth of a Variant of (Prof. J. M. Wiame and S. Bourgeois), 310
B. anthracis : Structure of Poly-D-glutamic Acid isolated from Capsulated Strains of (Prof V. Bruckner, J Kovács and G. Dénes), 508
Bact. coli as a Food Supplement (R. S. Roberts), 361
Bacteria (Aerobic Spore-forming) . Crystalline Inclusions in (Dr. C. L. Hannay), 1004
Bacteria (Green) · Taxonomy of (Dr. E. C. Pringsheim), 167
Bacteria (Soft-rotting) : A Method of Isolating, from Soils (Allen Kerr), 1155
Bacteria-free *Entamoeba invadens* (Dr. Max J. Miller), 1192
Bacterial Extracts : Dissimilation of Citric Acid by (S. Dagley and Dr. E. A. Dawes), 345
Bacteriology (Applied), Society for Symposium on Antibiotics, their Production and Use in Industry, 329
Bacteriophage 72 : Chemical Mutagenesis in (Robert L DeMars), 964
Bacteriostatic Activity of 3,500 Organic Compounds for *Mycobacterium tuberculosis* var. *hominis* (Prof. Guy P. Youmans, Leonard Doub and Anne S. Youmans), *review* by Dr. Vincent C. Barry, 322
Bacterium (Red Halophilic) Aspartate–Glutamate Transaminase in a (J. Robinson and H. Katznelson), 672
Baddar, Dr. Fawzy G., and others : The Fries Reaction, 1186
Baden-Powell, D. F. W. : Correlation of Pliocene and Pleistocene Marine Beds, 762
Badger, Dr. G M., and McKenzie, H. A. : Bond-Orders in Aromatic Compounds, 458
Bagley, A. S. · High-Frequency Electrical Measurements, 53

Cameron, Prof. G. R. : Anticholinesterases, 843
Cameron, M. L. : Secretion of an Orthodiphenol in the Corpus Cardiacum of the Insect, 349
Cameroon Women : Economic Position of (G. I. Jones), 152
Cammack, R. H. (Stanton, W. R., and) : Resistance to the Maize Rust, *Puccinia polysora* Underw., 505
Campbell, Bruce : Finding Nests, *review* by Frances Pitt, 828
Campbell, Dr. Colin : *Obituary* by Prof. E. R. H. Jones and Dr. G. Norman Burkhardt, 610
Campbell, N.   Elected a Fellow of the Royal Society of Canada, 1176
Campbell, Dr. P. N. (Work, Dr. T. S., and) : Nucleic Acid Template Hypotheses, 541
Campbell, Rosa M., and others : Cortisone and the Metabolic Response to Injury, 158
Campion, P. J. : Ionization Phenomena in Gases, 799
Canada : The Development of, 1083
Canada's Tomorrow (Canadian Westinghouse Company's Conference on), 1083
Canadian Engineers : Athlone Fellowship Scheme for (Dr. W. Abbott), 758
Canadian High Polymer Forum   Fifth, 708
Canadian Power : Springs of (Royal Institute of International Affairs), 442
Canadian Westinghouse Company   Conference on Canada's Tomorrow, 1083
Cancer : Sex Hormones and, *review* by Prof. W. S. Bullough, 1066
Cancer Campaign, British Empire   Thirtieth Annual Report, 788
Cancer Research   Progress of, 788
Cancer Research in the University of Leeds, 1028
Canines   The Australopithecine Milk (Dr. J. Bronowski and W. M. Long), 251
Cannabis sativa L. : Action of Gamma-Rays on Seeds of (J. Moutschen and Dr. J. Govaerts), 350
Cantabrigienses : Alumni (compiled by Dr. J. A. Venn), Part 2, From 1752 to 1900, Vol. 5, Pace–Spyers, *review* by Prof. F. J. M. Stratton, 825
Capillary-condensed Water : Boiling Point of (M. L. Lakhanpal and Dr. B. R. Puri), 917
Caplin, S. M. (Steward, F. C., and) : Coconut Milk Growth Factor, 102
Capraro, Prof. V. : A New Method of Measuring Oxygen consumed in the Metabolism of Small Animals, 815
Capstick, E. S.   Appointed deputy director of agriculture (crop husbandry), Trinidad, 571

Capsulated Strains of *B. anthracis* Structure of Poly-D-glutamic Acid isolated from (Prof. V. Bruckner, J Kovács and G. Dénes), 508
Carbazoles A New Synthesis of (Alfred Loffler and David Ginsburg), 820
Carbon (Deposited) · Density of (A. R. G. Brown, A R Hall and W. Watt), 1143
Carbon in Organic Media Stability and Settling of Dispersions of (Prof. F H. Garner, M. F. Mohtadi and Dr C. W. Nutt), 259
C_{18}-C_{24} Saturated Straight-Chain Fatty Acids A Simple Chromatographic Method for the Determination of the (H. J. Nijkamp), 1102
C_{12}-C_{22} Fatty Acids Analytical Separation of the Methyl Esters of the, by Vapour-Phase Chromatography (F. R. Cropper and A. Heywood), 1101
Carbon Dioxide in Solutions of Ethyl Alcohol · Polarographic Effect of (Dr. A A. Vlček), 861
Carbon Dioxide Fixation and Mitotic Poisons (Dr. S. Aronoff and G. E. Graf), 1043
Carbon Monoxide · Influence of some Impurities, notably Potassium, upon the Reactivity of Iodine Pentoxide towards (E. G. Adams and N. T. Simmons), 1104
Carboniferous (Upper) A Presumed Ascomycete from the (Dr S. A. Hutchinson and Prof. J. Walton), 36
N-Carboxy-α-amino-acid Anhydrides · Kinetics of the Formation of Polypeptides from (D G. Ballard and Dr. C. H. Bamford), 907
2-Carboxy-pyrrole in Mucoproteins Presence of, and its Relation to the Viral Enzyme (Dr. A Gottschalk), 808
Carboxylic Acids in the presence of Pyridine Action of Thionyl Chloride on (J A Cade and Dr. W. Gerrard), 29
Carcinogens and Oxidized Fatty Acids in the Skin (Mary L C. Bernheim, Prof. Frederick Bernheim and Karl M. Wilbur), 306
Carcinoid Tumour 5-Hydroxytryptamine in a (Dr. F Lembeck), 910
Carcinoma Cells (Ehrlich Ascites) . Fixation of Radioactive Colchicine by (A Back and E. J. Walaszek), 202
Cardiac Muscle Intracellular Distribution of Rhodanese in (Jennifer M. Moyle), 508
Careers in Chemical Engineering (Prof H. E Watson), 489
Caribbean Meteorological Service, British · First Annual Report, 279
Carlisle, David B. Origin of the Pituitary Body of Chordates, 1098

Chromatographic Behaviour of Intermedin as determined by *in vitro* Assays (Robert R. Kohn), 1185
Chromatographic Colour Reagent for a Group of Amino-Acids (Dr. G. Curzon and J Giltrow), 356
Chromatographic Method for the Determination of the C_{12}–C_{22} Saturated Straight-Chain Fatty Acids : A Simple (H. J. Nijkamp), 1102
Chromatographic Separation, using Chemically Treated Paper, of Aldehydes and Ketones on the Basis of their Reactivity (Dr. A. G. Newcombe and Dr. S. G. Reid), 455
Chromatographie . Progrès récents de la (Dr. Edgar Lederer), Première partie et Deuxième partie, *review* by Dr. F. H Burstall, 1020
Chromatographie (Papier-), (Dr. Friedrich Cramer), zweite Auflage, *review*, 7
Chromatography . Antibody, on an Immunologically Specific Adsorbent (L. S. Lerman), 635
  Paper (Richard J. Block, Raymond LeStrange and Gunter Zweig), *review* by Dr. G. Leaf, 4
  Paper, of Amino-Acids in Cerebrospinal Fluid (A P. Prior and T. P. Whitehead), 358
  Paper, of Keto-Acids (Mrs. Dorothy Turnock), 355
  Quantitative Paper, of Traces of Metal with the Aid of Radioactive Hydrogen Sulphide (P. C van Erkelens), 357
  Two-dimensional Paper, of Radioactive Substances (F. P W. Winteringham), 727
Chromatography (Circular Paper) : Identification of Amino-Acids present in Purified Prothrombin by (Gauranga Ray, N. C. Ganguli and S. C. Roy), 809
Chromatography (Inorganic Paper) : Gradient-Elution Analysis in (Dr. Michael Lederer), 727
  New Method of Direct Quantitative (S. V. Vaeck), 213
Chromatography (Paper) : Detection of 5-Hydroxytryptamine by (Dr. D. M. Shepherd, Dr. G. B. West and Dr. V. Erspamer), 357
  'Multiple Dipping' Procedures in—a Specific Test for Hydroxy-proline (Dr. John B. Jepson and Ivor Smith), 1100
Chromatography (Sugar) : Salt Interference in, of Urine (Dr. S. Baar and Dr. J P. Bull), 414
Chromatography (Vapour-Phase) · Analytical Separation of the Methyl Esters of the C_{12}–C_{22} Fatty Acids by (F. R. Cropper and A. Heywood), 1101
Chromium · Thermal Anomaly in the Elastic Constants of (H. Pursey), 864
Chromium (Hexavalent) Szilard and Chalmers Effect by Irradiation of, in an Atomic Pile (Dr. B. Ottar), 362
Chromium Oxide–Alumina Catalysts : Electrical Properties of (Dr. R. Chaplin, P. R. Chapman and Dr. R. H. Griffith), 77
Chromosomal Inversions with Sex-limited Effects (Dr. A. Brito da Cunha), 815
Chromosome Breakage Experiments with Endosperm—Sub-chromatid Breakage (L. F. La Cour and A. Rutishauser), 501
Chromosome Numbers in the Desmids (G. C. King), 592
Chromosome Variation . Sub-Diploid, in Man and other Mammals (Dr. Leo Sachs), 205
Chromosomes Regular Occurrence of the Haploid Number of, in Mesenchymal Cells of the Tail Tip of *Rana pipiens* Tadpoles (Dr. Elizabeth Ufford Green), 766
  Sex, of *Ranatra elongata* (Dr. M. D. L. Srivastava and C. C. Das), 505
Chromosomes (Salivary) . Application of Nigrosine to the Study of (Ramon Parés), 1151
Chromosomes (Supernumerary) Prochromosomes and, in *Rhinanthus minor* Ehrh. (David J. Hambler), 629
Chromosomes of *Phylloglossum drummondii*, Kunze (M. Blackwood), 591
Chromosomes of the Silkworm · Action of Irradiated Cytoplasm on Untreated (Prof. Yoshio Nakao), 625
Chronometry International Congress of (Société Chronométrique de France), 942
Church, H. F., and Garton, C. G. · Electrical Insulation, 9
Churchill, J. L. W., and others : Half-value Periods for the Decay of Aluminium-26, Aluminium-25 and Nitrogen-13, 460
Ciaranfi, Prof. E , and Fonnesu, A. Utilization of Acetate in Experimental Diabetes, 961
Cicadas Physiology of Song in (Dr. J. W. S. Pringle), 248
Cichlid Fish, *Tilapia esculenta* Graham . Feeding Mechanism of the (P. H. Greenwood), 207
Circulation in *Lacerta viridis* (G. E H. Foxon, J. Griffith and Myfanwy Price), 312
Cirrus Clouds · Orographic (F. H. Ludlam), 339
Cis-Trans Isomerization and the Ceiling Temperature Phenomenon in Polymerization (Prof F S. Dainton and G. M Bristow), 804
Citric Acid : Effect of, on the Growth of a Variant of *Bacillus subtilis* (Prof. J. M. Wiame and S. Bourgeois), 310
  Dissimilation of, by Bacterial Extracts (S. Dagley and Dr E. A. Dawes), 345
City and Guilds of London Institute Report of the Council for the Year 1952, 483
Civil Engineers, Institution of · Conference on the North Sea Floods, 1030
Civil Engineers, Institution of, and others (Joint Committee of) · Conference on Welded Steel Structures, 485
Civil Service · Recruitment for the, 990
Civil Service Fellowships Colonial (Commonwealth Fund of New York), 612
  Dominion (Commonwealth Fund of New York), 612
  Home (Commonwealth Fund of New York), 612
Civil Service Commissioners, H.M . Report for 1949–1952, 990
Civil Service, Scientific Promotion of Individual Research Workers, 657
Clapham, Dr. P A. : Pseudotuberculosis among Stock-Doves in Hampshire, 353
Clar, Dr. E. Ultraviolet Spectra of Aromatic Compounds, *review*, 223
Clare, K. E. : Mixing of Thick Liquids, Pastes and Slurries, 846
Claringbold, P. J , and others. Vaginal Cornification of the Mouse produced by Œstrogens *in vitro*, 1196
Clark, F. Le Gros Food Supply and Consumption in Great Britain, *review*, 47
Clark, Prof. W. E. Le Gros, and others Piltdown Man, 981
Clarke, Dr. A. S. Appointed assistant keeper in the Department of Natural History in the Royal Scottish Museum, 1085
Clarke, L. U. Appointed assistant director of the East African Statistical Department, 60
Classical Considerations on the Abnormal Properties of Helium-4 (S. P B. Tyabji), 849
Classification of Information on Rubber · Revised System of (Research Association of British Rubber Manufacturers, the Rubber-Stichting, Delft, and the Institut Français du Caoutchouc, Paris), 144
Clay Movement in Podzolized Soils · Sesquioxide Immobilization and (Dr. C. Bloomfield). 958
Clay-Gels (Dry) Preparation of, by Freeze-drying (F Call), 126
Clays : Advances in Methods of Studying (Clay Minerals Group of the Mineralogical Society Discussion on), 287, *erratum*, 1085
Clays (Varved) Remanent Magnetism of, from Sweden (D. H. Griffiths), 539
Clayton-Cave, J. : Plastic Deformation of Metals, 572
Cleavage Fracture of Zinc Single Crystals (A. E. Deruyttere and G B. Greenough), 170
Clegg, H. · Empirical Research in Industry, 897
Clegg, H A , and Chester, T. E. : The Future of Nationalization, 44
Clegg, Dr. J. A. (Lovell, Prof Bernard, and) : Radio Astronomy, *review* by J. A. Ratcliffe, 47
Clegg, Dr. L. F. L. : Adaptation in Micro-organisms, 236
Clemen, W. A. : Presidential Address to Section V (Biological Sciences) of the Royal Society of Canada, 1175
Clemo, Prof. G. R. : Organic Chemistry since 1837, 430
Clinical Research Board · Appointed by the Medical Research Council, 1130
Clocks of the Greenwich Time Service ; Quartz (H. M Smith), 984
Close Proximity · Interaction between Surfaces in (L P Evans), 776
Close Spacing · Effects of, on the Growth of Garden Beet (Dr. L. G G. Warne), 506
Cl. welchii : Agglutination of Red Cells by (E N. Dafaalla and Dr M. A Soltys), 38
Clothworkers, Worshipful Company of · Renewal of three grants (special maintenance grant, a research grant, and a Dyeing Department research grant) for the Clothworkers' Department in the University of Leeds, 895
Clouds : Orographic Cirrus (F. H. Ludlam), 339
Clover (White) An Irreversible Choline-esterase Inhibitor in (D. F. Heath and P. O. Park), 206
Coagulation of the Blood · Substances in Bone-Marrow Extract accelerating (Katashi Makino and Hong Rih-ching), 205
Coal as a Source of Chemical Raw Material (Dr. R Holroyd), 613
Coal Board, National Grants of £600, £250 and £550 for special researches in the Department of Mining, and £3,000 to the University of Leeds, 895
Coal Science Lecture of the British Coal Utilisation Research Association (Dr. R. Holroyd), 613
Coal Utilisation Research Association, British: Coal Science Lecture (Dr R Holroyd), 613
Coast of Devon . Occurrence of *Asparagopsis armata* Harv on the (Joy Kerslake), 874
Coasts (British) : Guide to the Identification and Reporting of Stranded Whales, Dolphins, Porpoises and Turtles on the (F C. Fraser and H. W. Parker), 334
Coates, Prof. G. E. Appointed professor of chemistry in the University of Durham, 611 ; work of, 611
Cobalt Ferrite at Low Temperatures Crystal Structure and Magnetic Properties of (H. P. Rooksby and B. T. M. Willis), 1054
Cobbold, A., and others Fine Structure in Polyethylene Terephthalate Fibres, 806
Cocaine Inhibitory Action of (Brenda E. Ryman and Dr. E. O'F. Walsh), 679
Cochran, W., and others . Structure of Adenylic Acids *a* and *b*, 1184
Cochrane, D G. : Appointed scientific officer, East Africa High Commission, 1030
Cockburn, Dr. R. : Appointed principal director of scientific research (guided weapons and electronics) to the Ministry of Supply, 1131
Cockburn, R., and others : Action of Ninhydrin on Keratin, 75
Cockcroft, Sir John The Development of Radiochemistry and Radiation Chemistry (Dalton Lecture of the Royal Institute of Chemistry), 895
Coconut Milk Growth Factor (F. C. Steward and S M. Caplin), 102
Coconut Nutfall and Gummosis : Causes of (Dr. F. L. Vanderplank) 315
Coenzyme A Levels · Effect of Thyroxine on (Irving L. A. Tabachnick and Prof. Desmond D. Bonnycastle), 400
Coercivity (High) New Magnetic Materials of (Prof. L. F. Bates), 97
Coffey, Dr. S . *Obituary* of Prof A. F. Holleman, 706
Cohen, Sir Henry : The University of Liverpool (1903–53), 271

Cohn, Dr. M. : Adaptation in Micro-organisms, 235
Cohn, Dr M., and others Terminology of Enzyme Formation, 1096
Colchicine : Behaviour of a *Triticum* × *Secale* Hybrid under the Action of (Prof. Edmond Villax and Miguel Mota), 412
Colchicine (Radioactive) : Fixation of, by Ehrlich Ascites Carcinoma Cells (A. Back and E. J. Walaszek), 202
Cold Auto-Agglutinins Specificity of Complete (Lieut.-Colonel G. W. G. Bird), 734
Cole, Prof. F. J. . Leeuwenhoek's Letters, *review*, 696
Cole, Dr. H. A. . New Fisheries Laboratory, Burnham-on-Crouch, 790
Cole, Dr. H. A., and Baird, R. H. : The American Slipper Limpet (*Crepidula fornicata*) in Milford Haven, 687

Cole, Prof. R. H. (Hassion, F. X., and): Dielectric Relaxation Processes in Ethanol), 212
Collagen (Reconstituted): A Soluble Form of (D. S. Jackson and J. Bail), 1046
Collagen and its Dissolution with Elastase: Thermal Contraction of (Dr. I. Banga), 1099; (Dr. D. A. Hall, Prof. R. E. Tunbridge and G. C. Wood), 1100
Collège de France, Paris: Appointment of Dr. S. J. Folley as a visiting professor, 942
Colli, L.: Ionization Phenomena in Gases, 799
Collins, J. B. (Chesterman, W. D., and): Awarded jointly the Leon Gaster Memorial Premium of the Illuminating Engineering Society, 709
Collins, W. B.: Appointed a senior assistant conservator of forests, Gold Coast, 234
Collip, Dr. J. B.: Address at the XIX International Physiological Congress, Montreal, 1071
Collis, Miss M.: Field Studies in Urban Areas, 1032
Collison, R. W. L.: Library Facilities in the United States, 191
Colloid Science (edited by H. R. Kruyt), Vol. 1, Irreversible Systems, *review* by Dr. D. P. Riley, 741
Colloid Science and some of its Industrial Applications (Dr. R. Matalon), 19
Collumbine, Dr. H.: Anticholinesterases, 842
Colonial Civil Service Fellowships (Commonwealth Fund of New York), 612
Colonial Development Corporation: Annual Report for 1952, 569
Colonial Fisheries Research Stations: Visitors' Tables at (Dr. C. F. Hickling), 885
Colonial Insecticide Research Unit, Tanganyika: Appointment of G. W. Ivens as senior scientific officer (botanist), 571
Colonial Office: The Colonial Territories 1952–53, 1034
Colonial Service: Appointments and promotions, 60, 234, 571, 753, 1030, 1085
Colonial Territories: Technical officers in Agricultural Departments of (Secretary of State for the Colonies), 187
Colonial Territories (British): Research and Development in, 1034
Colonial Welfare and Development: British, during 1952–53, 283
  Funds for, 57
Colonization and Survival of Soil *Fusaria* in Detached Plant Tissue: Measurement of (Dr. R. H. Stover), 465
Coloration. Phase, in Lepidopterous Larvae (K. M. Doull), 813
Colorimetric Estimation of Sugars using Benzidine (Dr. J. K. N. Jones and J. B. Pridham), 161
Colorimetric Method, based on Metallic Complex Formation, for the Detection of Aureomycin in presence of Amino-Acids and Proteins (Dr. A. E. Oxford), 395
Colour Bands in Fluorspar (Prof. K. Przibram), 860
Colour Reagent for a Group of Amino-Acids: A Chromatographic (Dr. G. Curzon and J. Giltrow), 356
Colour-Vision Defect. A Pedigree for Three Types of (Dr. R. W. Pickford), 1010
Coloured *Cyclopentadiene* Polymers: Proton Acceptor Properties of Deeply (B. Eisler and Dr. A. Wassermann), 73
Comber, Prof. N. M.: Retirement as head of the Department of Agriculture and professor of agriculture in the University of Leeds, 278; work of, 278
  Title of emeritus professor of agricultural chemistry in the University of Leeds conferred on, 895
Combridge, J. T.: *Obituary* of Prof. J. B. Dale, 276
Combustion (Hydrocarbon): Chemiluminescent Phenomena during (Prof. R. G. W. Norrish, Dr. G. Porter and B. A. Thrush), 71
Comet of November 1948, 280
Comets and Meteor Streams (Dr. J. G. Porter), *review* by Dr. M. Davidson, 883
Comets and Meteors, *review* by Dr. M. Davidson, 883
Comfort, Dr. Alex: Absence of a Lansing Effect in *Drosophila subobscura*, 83
Comline, Dr. R. S.: Ruminant Digestion, 834
Commercial Solvents Award in Antibiotics awarded to Dr. Ibert C. Wells, Dr. Edwin E. Hays, Dr. E. A. Doisy and Dr. William L. Gaby, 382
Commercial and Radiation-produced Hydrogen Peroxide. Effects of (Tikvah Alper), 957
Commission on Higher Education for Africans in Central Africa: Report of the, 1
Commissione Nazionale Italiana per l'Ottica, and others: Conference on Optics and Microwaves, 102
Common, R.: Appointed lecturer in geography at the University of Glasgow, 1030
Commonwealth (British): Academic Mobility in the (Sir Charles Morris), 271
Commonwealth Bureau of Pastures and Field Crops: To be transferred to Hurley, Berkshire, and attached to the Grassland Research Station, 58, 278
Commonwealth Bursaries Scheme (Royal Society and the Nuffield Foundation), 185
Commonwealth Fund of New York: Fellowships for Study and Travel in the United States, 611
Commonwealth Scientific Office (British), North America: BCSO Review of Science in U.S.A. for the Year ending June 1952, 282
Commonwealth Scientific and Industrial Research Organization, Melbourne: List of Publications to December 1952, 234
  Directory and Catalogue of Micro-organisms maintained in Australia, 484
  Foundation of the William McIlrath Fellowship for research and teaching in Animal Husbandry, 794
  Annual Report for 1951–52, 978
  Retirement of Dr. F. L. Stillwell as officer-in-charge of the Mineragraphic Section, 983
  Appointment of Dr. A. B. Edwards as officer-in-charge of the Mineragraphic Section, 983
Communication Engineering: Harmonics, Side-bands and Transients in (C. Louis Cuccia), *review* by F. Horner, 5
Communities: Natural (Lee R. Dice), *review* by Prof. Ronald Good, 45
Community Concept in Ecology, *review* by Prof. Ronald Good, 45
Components of the Vitamin B Group: Synthesis of, by *Corynebacterium diphtheriae* (Lauri Jannes), 400
Compounds: Heterocyclic (edited by Robert C. Elderfield), Vols. 3 and 4 *review* by Prof. J. W. Cook, 882
  Toxic Fluorine (Dr. F. L. M. Pattison), 1139
Compounds (Aromatic): Bond-Orders in (Dr. G. M. Badger and H. A. McKenzie), 458
  Phenylation, Benzoyloxylation and Halogenation of, by Silver Benzoate Halogen Complexes (Dr. D. Bryce-Smith), 863
  Ultraviolet Spectra of (Dr. Robert A. Friedel and Dr. Milton Orchin) *review* by Dr. E. Clar, 223
Compounds (Organic): The Bacteriostatic Activity of 3500, for *Mycobacterium tuberculosis var. hominis* (Prof. Guy P. Youmans, Leonard Doub and Anne S. Youmans), *review* by Dr. Vincent C. Barry, 322
  A New Method of Separation of (R. C. Vasisth and Dr. M. S. Muthana) 862
  Tables of Percentage Composition of, C—H—O, C—H—N, C—H—O—N, C—H: C—H—S, C—H—O—S, C—H—N—S, C—H—O—N—S (Dr. H. Gysel), *review* by Prof. J. W. Cook, 48
Compounds of Graphite: New Molecular (R. C. Croft), 725
Compounds of Tertiary Amines with Nitrosyl Chloride and with Dinitrogen Tetroxide (Dr. Alan E. Comyns), 491
Compton, Prof. Arthur H.: Science and the Discovery of Human Values, 476
Computers for Electrical Systems: Analysers and (Vacation School at the Imperial College of Science and Technology), 614
Computing the Optimum Size-Limit for a Fishery. A Method for (K. Radway Allen), 210
Computing Machines: The Utilization of Digital, in Engineering and Industry (British Association for the Advancement of Science, Section G (Engineering), Symposium on), 649
Computing Machines (Automatic Digital). Programme Design for (University of Cambridge Mathematical Laboratory Summer School in), 18
Comyns, Dr. Alan E.: Compounds of Tertiary Amines with Nitrosyl Chloride and with Dinitrogen Tetroxide, 491
Conant, James Bryant: Education and Liberty, the Role of the Schools in a Modern Democracy, 468
  Modern Science and Modern Man, *review* by R. Brightman, 557
Concentration and Concentration Gradient in Liquid Columns: An Interferometer for Simultaneous Observation of (Dr. W. Weinstein), 461
Concentration Gradient in Liquid Columns: An Interferometer for Simultaneous Observation of Concentration and (Dr. W. Weinstein), 461
Condensation Nuclei from Bursting Bubbles: Giant (A. H. Woodcock, C. F. Kientzler, A. B. Arons and D. C. Blanchard), 1144
Conductivity induced in Insulators by X-Rays: Effect of Temperature on the (N. W. Ramsey), 214
Conflict between Science and Religion: Some Aspects of the (Prof. H. H. Price), 709
Conflicts of Loyalties (Present Question Conference on), 1172
Conforto, Fabio: Funzioni Abeliane Modulari, Vol. 1, Preliminari e parte-gruppale, geometria simplettica, *review* by Prof. K. Mahler, 323
Congenital Hypoplastic Anaemia: A Disturbance of Tryptophan Metabolism in (Prof. K. L. Altman and Gerald Miller), 868
Congo: Essences Forestière et Bois du (Jean Louis et Joseph Fouarge), Fasc. 1, Introduction, 1177
  Gravity Survey in the (P. Herrinck), 258
Congo (Belgian): Forests of the (Prof. E. P. Stebbing), 1177
Conservation, Vol. 1, No. 2, 441
Consiglio Nazionale delle Ricerche, and others: Conference on Optics and Microwaves, 102
Constitution of Viruses: Nature and (Society for Visiting Scientists Symposium on), 105
Contact of Surfaces: Elastic Deformation and the (J. F. Archard), 918
Continental Shelf: The (British Association for the Advancement of Science, Sections C (Geology), D (Zoology) and E (Geography), Discussion on), 1070
Continental Shelf and Marine Research: National Sovereignty, the, 1063
Continuous-Wave Radio: Investigation of Travelling Disturbances in the Ionosphere by (Y. V. Somayajulu), 818; (B. Ramachandra Rao and E. Bhagiratha Rao), 819
Contraction of Collagen and its Dissolution with Elastase. Thermal (Dr. I. Banga), 1099; (Dr. D. A. Hall, Prof. R. E. Tunbridge and G. C. Wood), 1100
Contrast (High): Use of, in the Photography of Interference Fringes (J. M. Hough and B. J. Goldsmith), 1105
Control: Stability and, *review* by Prof. G. Temple, 515
Control (Automatic): Fundamentals of (G. H. Farrington), *review* by Prof. J. Greig, 91
Control in Mechanical Engineering: An Introduction to the Theory of (R. H. Macmillan), *review* by Prof. J. Greig, 91
Control of Mechanisms and Industrial Processes: Automatic, *review* by Prof. J. Greig, 91
Control of Multi-Resistant Houseflies (H. Wichmand), 758
Control of *Pseudomonas syringae* with Streptomycin (D. W. Dye), 683
Control of University Expenditure, 555
Control and Stability of Aircraft: The Principles of the (Prof. W. J. Duncan), *review* by Prof. G. Temple, 515
Convection (Thermal): Heat Transfer from Water to Ice by (J. M. Dumoré, H. J. Merk and Prof. J. A. Prins), 460
Conversion of δ-Aminolaevulinic Acid to Porphobilinogen in a Tissue System (Dr. E. I. B. Dresel and Dr. J. E. Falk), 1185
Conversion of Plant Nitrogen to Microbial Nitrogen in the Rumen of the Sheep (P. V. Gray, A. F. Pilgrim and R. A. Weller), 347
Conversion-Electron from the Decay of Ionium: Angular Correlation of α-Particle and (Dr. R. R. Roy and Miss M. L. Goes), 360
Conway, Dr. B. E.: Electrochemical Data, *review* by Dr. J. C. Speakman, 269
Conway, Dr. B. E. (Butler, Prof. J. A. V., and): Effects of Salts on Interactions in Polyelectrolyte Solutions, 153
Cook, Dr. G. B., and Duncan, Dr. J. F.: Modern Radiochemical Practice, *review* by G. R. Martin, 267
Cook, J. Stewart: International Scientific Film Association—Annual Congress in London, 1133
Cook, Prof. J. W.: Tables of Percentage Composition of Organic Compounds, *review*, 48
  'The Merck Index', *review*, 220
  Polycyclic Nitrogen Heterocycles, *review*, 882
Cooke, Dr. R. G.: Elements of the Topology of Plane Sets of Points, *review*, 325

Courtaulds, Ltd. : Gift of £1,550 to the Clothworkers' Departments of the University of Leeds, 187
Courtaulds' Scientific and Educational Trust Fund : Awards, 383
Cousteau, J. Y., with Dumas, Frédéric : The Silent World, *review* by Dr. A. J. Brook, 370
Coutagne, A. : Elected correspondant for the Section of Geography and Navigation of the Paris Academy of Sciences, 185
Cow : Extremely High Alkaline Phosphatase Activity in the Vaginal Mucus of the (Dr. G. A. van Klinkenberg), 397
Cow and Buffalo Milk Fat : *Iso*-Oleic Acids in (S. S. Phatak and V. N. Patwardhan), 456
Cowan, jun., C. L., and others : Determination of Total Body Radioactivity using Liquid Scintillation Detectors, 521
Cowan, Dr. H. J. : Resignation as lecturer in civil engineering at the University of Sheffield, 146
  Appointed to the chair of architectural science in the University of Sydney, 568; work of, 568
Cracks in Glass Rod : Transverse (E. R. W. Jones and P. L. Pratt), 463
Craftsman in the Engineering Industries (D. B. Welbourn), 1088
Craggs, J. D. : Ionization Phenomena in Gases, 798
Craig, Sir John : The Mint, a History of the London Mint from A.D. 287 to 1948, *review* by Prof. F. C. Thompson, 221
Craig, Dr. R. E. : The Continental Shelf, 1070
Cramer, Dr. Friedrich : Papierchromatographie, zweite Auflage, *review*, 7
Crampton, Dr. Charles F., and others : Separation of Calf Thymus Deoxyribonucleic Acid into Fractions of Different Composition, 289
Cranbrook Institute of Science : Exhibition to illustrate the Sources and Biology of Hair and Fur transferred to Britain for circulation by the Museums Association, 144
Crane, M. B., and Lawrence, W. J. C. : The Genetics of Garden Plants, fourth edition, *review* by Prof. S. C. Harland, 7
Cranston, Maurice : Freedom, a New Analysis, 218
Crathorn, Dr. A. R. : Use of an Acetylene-filled Counter for Natural Radiocarbon, 632
Crawley : *Radar-Sonde* Meteorological Station at (Mullard, Ltd.), 440
Creep Curve for a Precipitation-hardened Alloy (G. C. E. Olds), 999
Crepidula fornicata in Milford Haven : The American Slipper Limpet (Dr. H. A. Cole and R. H. Baird), 687
Crescitelli, Dr. F., and Dartnall, Dr. H. J. A. : Human Visual Purple, 195
Cripps, C. T. : Gifts of £100,000 to the University of Nottingham for the endowment of two professorial chairs, 1129
Crisp, Dr. D. J., and others : Use of X-Ray Spectroscopy for examining Shipworm Infestation *in vivo*, 408
Crisp, Dr. D. J., and Southward, Dr. A. J. : Isolation of Intertidal Animals by Sea Barriers, 208
Critical Point : Restricted Rotation in Polar Gases near the (Frank E. Harris and Berni J. Alder), 774
Crocus sativus Linn. : Riboflavine and Thiamine Contents of Saffron (Prof. J. V. Bhat and Rajul Broker), 544
Croft, R. C. : New Molecular Compounds of Graphite, 725
Croft, W. N. : *Obituary* by W. N. Edwards, 523
Crombie, A. C. : Augustine to Galileo, the History of Science A.D. 400–1650, *review* by Dr. W. P. D. Wightman, 1334
Croneis, Dr. Carey : Appointed provost and Harry Carothers Wiess professor of geology in the Rice Institute, Houston, Texas, 103
Crop Conference (National Institute of Agricultural Botany), 797
Cropper, F. R., and Heywood, A. : Analytical Separation of the Methyl Esters of the C_{12}–C_{22} Fatty Acids by Vapour-Phase Chromatography, 1101
Crosbie, A. J. : Appointed soil survey officer, Department of Soil and Land Use Survey, Gold Coast, 753
Cross, J. R. : Appointed by the Royal Society to a Mr. and Mrs. John Jaffé Donation Studentship at the Physical Chemistry Laboratory, University of Oxford, 185
Cross-Fertilization of Spring and Autumn Spawning Herring : Sperm Storage and (J. H. S. Blaxter), 1189
Cross-Striations in Muscle : Structural Basis of the (Dr. Jean Hanson and Dr. Hugh E. Huxley), 530
Crowe, Leslie K. (Lewis, Dr. D., and) : Theory of Revertible Mutations, 501
Croxatto, Prof. H., and Barnafi, L. : Anti-Diuretic Substances of the Blood, 304
Crustaceans : Neurohaemal Organs in (David B. Carlisle and Dr. Francis G. W. Knowles), 404
Cryptolaemus montrouzieri Mulsant in South India (W. Wilson Mayne), 85
Cryptostroma corticale : Sooty Bark Disease of Sycamore (Forestry Commission, Leaflet No. 30), 947
Crystal Slip and Grain Boundary Movement : Interaction between (D. McLean), 300
Crystal Structure and Magnetic Properties of Cobalt Ferrite at Low Temperatures (H. P. Rooksby and B. T. M. Willis), 1054
Crystalline Deoxypentose Nucleic Acid : Helical Structure of (Dr. M. H. F. Wilkins, Dr. W. E. Seeds, Dr. A. R. Stokes and Dr. H. R. Wilson), 759
Crystalline Inclusions in Aerobic Spore-forming Bacteria (Dr. C. L. Hannay), 1004
Crystalline Structure of Sodium Deoxyribonucleate : Evidence for 2-Chain Helix in (Rosalind E. Franklin and R. G. Gosling), 156
Crystallographic Equipment (X-Ray) : Exhibition of (X-Ray Analysis Group of the Institute of Physics), 336
Crystallography : International Congress on (International Union of Crystallography), 613
Crystallography, International Union of : Third General Assembly and International Congress, 613
Crystals : Relation between Frank Spirals and Spiral Pits in (S. Amelinckx and E. Votava), 538
Crystals (Nearly Perfect) : Imperfections in (Symposium held at Pocono Manor, October 12–14, 1950, sponsored by the Committee on Solids, Division of Physical Sciences, the National Research Council), *review* by Dr. H. Lipson, 266
Crystals (Zinc Single) : Cleavage Fracture of (A. E. Deruyttere and G. B. Greenough), 170
Cuccia, C. Louis : Harmonics, Sidebands and Transients in Communication Engineering, *review* by F. Horner, 5
Cucurbit Plants in Bihar : Ozonium Wilt of Guar and (J. N. Mishra), 209
Culex (culex) fatigans Wiedemann : Observations on the Anal Papillae of (James G. Halcrow), 1156
Culshaw, Dr. W. : Electrical Insulation, 8
Cultivation of Poplars, 759
Cultural Anthropology, *review* by Dr. Paul Bohannan, 972
Culture : The Nature of (A. L. Kroeber), *review* by Dr. Paul Bohannan, 972
Culture of *Fucus* Hybrids (E. M. Burrows and S. M. Lodge), 1009
Cummings, R. H. : Appointed lecturer in geology at the University of Glasgow, 1030
Cundy, H. Martyn, and Rollett, A. P. : Mathematical Models, *review*, 94
Cunningham, Dr. W. R. : *Death* of, 938
Cure of Enzootic Muscular Dystrophy in Beef Cattle : Prevention and (Dr. K. L. Blaxter and G. A. M. Sharman), 1006
Currents in the North Atlantic : Oil Pollution Research—Plotting of (National Institute of Oceanography), 750
Curtis, P. J., and others : Humicolin, a New Antibiotic, 187
Curzon, Dr. G., and Giltrow, J. : A Chromatographic Colour Reagent for a Group of Amino-Acids, 356
Cusick, G. E. : Awarded a postgraduate research scholarship by Courtaulds' Scientific and Educational Trust Fund, 383
Cuthbertson, Dr. D. P. : Organic Manures and Fertilizers, 12
  Quality and Quantity of Protein for Man and Livestock, 434

Cuthbertson, Dr. D. P., and others : Cortisone and the Metabolic Response to Injury, 158
Cuthbertson, Dr. J. W. : Elected president for 1953–54 of the Institute of Metal Finishing, 336
Cuthbertson, Dr. J. W., and others : Awarded jointly the Westinghouse Brake and Signal Co., Ltd. Prize for 1952–53 by the Institute of Metal Finishing, 656
Cuticular Waxes (Insect) : A New Method for Determining the Transition Temperature of (P. J. Judge), 405
Cutolo, Enrico, and others : Uridyl Transferases and the Formation of Uridine Triphosphate—Enzymic Production of Uridine Triphosphate, Uridine Diphosphoglucose Pyrophosphorolysis, 1036
Cutolo, Dr. M. Measurements of the Terrestrial Magnetic Field in the E-Layer, 774
Cuttell, J. R., and others : Milk Pasteurization, Planning, Plant Operation and Control, 335
Cwilong, Dr. B. M. : To undertake a Meteorological and Magnetic Survey of the Pacific and other Oceans, 839 ; work of, 839
Cyanol in the Study of Blood-vessels in Sheep Skin : Use of (M. L. Ryder), 125
Cybernetics (British Association for the Advancement of Science, Sections J (Psychology), A (Physics) and I (Physiology), Symposium on), 648
*cyclo*Hexane Bonds Nomenclature of (Prof. D. H. R. Barton, Prof. O. Hassel, Prof. K. S. Pitzer and Prof. V. Prelog), 1096
Cyclopentadiene Polymers Proton Acceptor Properties of Deeply Coloured (B. Eisler and Dr. A. Wassermann), 73
Cygnus I : Fine Structure of the Extra-terrestrial Radio Source (R. C. Jennison and M. K. Das Gupta), 996, *erratum*, 1030
Cylindrical Rods : Longitudinal Elastic Waves in (R. E. D. Bishop), 169
Cyprus (Western) : Earthquake in, 524
Cyrenaica : A Fossil Human Mandible from a Levalloiso-Mousterian Horizon in (Dr. C. B. M. McBurney, Dr. J. C. Trevor and Dr. L. H. Wells), 889
Cysteinamin : Protective Activity of, against the Toxicity of Dihydrostreptomycin (P. Kluyskens), 912
Cysteinamine, Methylamine and Cortisone : Influence of, on the Toxicity and Activity of Nitrogen Mustard (Dr. O. Peczenik), 454, *erratum*, 942
Cysteinylglycine : Isolation of a Mixed Disulphide of Glutathione and, from a Partial Hydrolysate of Glutathione (Dr. Eskil Wikberg), 398
Cysts of *Heterodera rostochiensis* : Hatching the Contents of, with Alternating Temperature Conditions (Daphne D. Bishop), 1108
Cyto-Scale : Nucleotide Analysis on the (Jan-Erik Edstrom), 809
Cytochrome *c* : Complex Reactions of (Prof. H. Lundegårdh), 303
Cytochrome Peroxidase from *Pseudomonas fluorescens* (Howard M. Lenhoff and Dr. Nathan O. Kaplan), 730
Cytological Forms of *Polypodium virginianum* in Eastern North America : Two (Prof. I. Manton and M. Shivas), 410
Cytoplasm (Irradiated) : Action of, on Untreated Chromosomes of the Silkworm (Prof. Yoshio Nakao), 625
Cytoplasmic Streaming in *Amoeba proteus* : Relation between Dye Uptake and (D. M. Prescott), 593 , (R. J. Goldacre), 593

DA CUNHA, Dr. A. Brito Chromosomal Inversions with Sex-limited Effects, 815
Defaalla, E. N., and Soltys, Dr. M. A. : Agglutination of Red Cells by *Cl. welchii*, 38
Dagley, S., and Dawes, Dr. E. A. : Dissimilation of Citric Acid by Bacterial Extracts, 345
Daily Variation of Amount of Ozone in the Atmosphere (Dr. K. R. Ramanathan and Bh. V. Ramana Murthy), 633
Dainton, Prof. F. S., and Bristow, G. M. : *Cis-Trans* Isomerization and the Ceiling Temperature Phenomenon in Polymerization, 804
Dairy Cattle : Effect of Two Systems of Management on Milk Yield and Body Temperature of (Dr. K. A. Alim), 1195
Dale, Sir Henry : Honorary doctorate in science of McGill University conferred on, 1074
Dale, Sir Henry Hallett (a Selection from the Scientific Publications of) : Adventures in Physiology, *review* by Prof. J. H. Gaddum, 825
Dale, Prof. J. B. : *Obituary* by J. T. Combridge, 276
Dalton, A. J., and others : Isolation and Biochemical Function of the Golgi Substances, 161
Dalton, D. C. : Ionization Phenomena in Gases, 799
Dalton, Dr. J. C., and others : Cosmic-Ray Production of Helium in Meteorites and their Ages, 1168
Dalton, N. N. (edited by Miner, Carl S., and) : Glycerol, *review* by Prof. T. P. Hilditch, 1066
Dalton Lecture of the Royal Institute of Chemistry (Sir John Cockcroft), 895
Dam, Prof. C. P. H. : Elected an Honorary Fellow of the Royal Society of Edinburgh, 57
Dana, James Dwight : Manual of Mineralogy, sixteenth edition, revised by Prof. Cornelius S. Hurlbut, Jr., *review*, 46
Dana, James Dwight, and Dana, Edward Salisbury : The System of Mineralogy of, 1837–1892, seventh edition, entirely rewritten and greatly enlarged by Charles Palache, the late Harry Berman, and Clifford Frondel, Vol. 2, *review*, 46
Danckwerts, P. V. : Mixing of Thick Liquids, Pastes and Slurries, 846
D'Ancona, Prof. : Baldi Memorial Lecture, 888
Darby, Prof. H. C. : The Domesday Geography of Eastern England, *review* by J. R. Hale, 1116
Dark-Ground Illumination of Ram Spermatozoa (H. M. Dott), 626
Darling, Henry S. Appointed head of the Hop Research Department of Wye College, 840 , work of, 840
Dartmoor (L. A. Harvey and D. St. Leger-Gordon), *review*, 928
Dartnall, Dr. H. J. A. (Crescitelli, Dr. F., and) Human Visual Purple, 195
Das, Dr. A. K., and Abhyankar, K. D. : Difference of Temperature between Pole and Equator of the Sun, 496
Das, Dr. A. K., and Bhargava, B. N. : Radio Noise-bursts from Solar *M*-Regions, 855
Das, Dr. A. K., and others : Recording Photoelectric Spectrophotometer at Kodaikanal Observatory, 383
Das, C. C. (Srivastava, Dr. M. D. L., and) Sex Chromosomes of *Ranatra elongata*, 505
  Heteropycnosis in the Autosome Segments of *Ceriagrion coromandelianum* (Odonata), 765
Das, Dr. R. K., and Sethumadhavan, K. : Eruptive Prominence of February 26, 1953, and Associated Radio Noise-Burst, 446
Das Gupta, M. K. (Jennison, R. C., and) : Fine Structure of the Extra-terrestrial Radio Source Cygnus I, 996, *erratum*, 1030
Dating Radiocarbon—Large-scale Preparation of Acetylene from Organic Material (Dr. H. Barker), 631
Daubeny, R. de P., and others : Fine Structure in Polyethylene Terephthalate Fibres, 806
Dauphinee, J. A. : Elected a Fellow of the Royal Society of Canada, 1176
Davenport, H. E., and others : Production of Oxygen from Chloroplast Preparations—Active Chloroplast Preparations from *Chlorella pyrenoidosa*, 948
Davey, J. T. : Possibility of Movements of the African Migratory Locust in the Solitary Phase and the Dynamics of its Outbreaks, 720
Davidson, G. (Draper, C. C., and) A New Method of Estimating the Survival-Rate of Anopheline Mosquitoes in Nature, 503
Davidson, Dr. M. : Comets and Meteors, *review*, 883
Davidson, S. H. At the fourth meeting of the European Association of Exploration Geophysicists, 190
Davies, Dr. A. E., and others : Awarded jointly the Westinghouse Brake and Signal Co., Ltd., Prize for 1952–53 by the Institute of Metal Finishing, 656
Davies, Dr. C. N. : Health, Welfare and Efficiency of the Worker, 1132
Davies, Dr. Emrys : Group Discussion, 799
Davies, Dr. H. G., and others : A Comparison between the X-Ray Absorption and Optical Interference Methods for the Mass Determination of Biological Structures, 1041
Davies, M. W. Humphrey : Analysers and Computers for Electrical Systems, 614
Davies, P. W. A. : Appointed agricultural officer, Kenya, 1030
Davies, Dr. William The Grass Crop, *review* by Prof. H. Ian Moore, 135
Davis, David, and others : Conjugated Phenols in the *Fusarium* Wilt Syndrome, 959
Davis, George E. (1850–1907) and Chemical Engineering (Prof. H. N. Rydon), 848
Davis (George E.) Memorial Lecture of the Institution of Chemical Engineers (Norman Swindin), 60, 848
Davison, Dr. A. N. : Anticholinesterases, 844
Davison, R. M. (Newhook, F. J., and) : Combined Hormone-Fungicide Sprays for Control of *Botrytis* Fruit-Rot in Glasshouse Tomatoes, 351
Davisson, J. W. : Impurity Phenomena, 386
Davy Medal of the Royal Society awarded to Sir John Lennard-Jones, 893, 1022
Dawe, E. C. S. : Appointed director of veterinary services, Tanganyika, 1030
Dawes, Dr. E. A. (Dagley, S., and) : Dissimilation of Citric Acid by Bacterial Extracts, 345
Dawes, G. S. : Reflexes from the Cardiac and Pulmonary Areas, 1073
Dawson, Sir Douglas Programme of Australian Antarctic Exploration, 479
Dawson, Dr. Ian M. Appointed senior lecturer in electron microscopy at the University of Glasgow, 1030
Dawson, P. A. P. : Appointed geologist, British Solomon Islands Protectorate, 753
Day, F. M. : Flowers of the Wood, *review* by L. J. F. Brimble, 324
Day, P. R. Genetical Aspects of Plant Disease, 989
Daylight (Technical Committee on Daylight of the International Commission on Illumination Conference on), 59
Daymond, Prof. J. R. : Higher Technological Education, 271
de Beer, Dr. G. R. Elected president of the Fifteenth International Congress of Zoology, 830
de Boer, Dr. J. H. The Dynamical Character of Adsorption, *review* by Prof. R. M. Barrer, 828
De Borde, A. H. : Appointed a Nuffield Fellow in the Department of Natural Philosophy, University of Glasgow, 1030
De Greve, L., and others : Determination of the Structure Factor of Thin Tin Films from Superconductivity Measurements, 952
De Keyser, Prof. W. L. Differential Thermobalance, a New Research Tool, 364
DeMars, Robert I. Chemical Mutagenesis in Bacteriophage T2, 964
De Robertis, E. D. Mechanism of Formation of the Thyroid Hormone, 1074
Deamination of Adenosine Diphosphate by Washed Myofibrils : Direct (H. L. Webster), 453
Dean, Dr. A. C. R. : Adaptation in Micro-organisms, 235
Dean, A. E. *Obituary* of T. Raymont, 480
Dean, Dr. F. M., and others Nidulin and 'Ustin', Two Chlorine-containing Metabolic Products of *Aspergillus nidulans*, 344
Decay of Aluminium-26, Aluminium-25 and Nitrogen-13 : Half-value Periods for the (J. L. W. Churchill, W. M. Jones and S. E. Hunt), 460
Decay of Ionium Angular Correlation of α-Particle and Conversion-Electron from the (Dr. R. R. Roy and Miss M. L. Goes), 360
Decentralisation Management under Nationalisation, Studies in (Acton Society Trust), 694
Decision in Business Affairs : Uncertainty, Expectation and (Prof. G. P. Meredith), 701
Decision-making under Uncertainty Logic, Philosophy and Psychology of Business (British Association for the Advancement of Science, Section F (Economics), Symposium on), 701
Decker, Dr. George C. : Toxic Hazards of Pesticides to Man, 1125
Deckker, B. E. L. Appointed lecturer in mechanical engineering at the University of Glasgow, 1030
Decomposition of Benzoyl Peroxide : Effect of Phenols on the Rate of (J. J. Batten and M. F. R. Mulcahy), 72
Decomposition of Dolomite : Thermal (Dr. Robert Meldau and Robert H. S. Robertson), 998
Decomposition of Peroxides : Kinetics of Porphyrin-catalysed Chemiluminescent, and the Mechanism of Photosensitized Oxidation (Dr. Henry Linschitz and Edwin W. Abrahamson), 909
Deep Scattering Layer in the Sea—Association with Density Layering (Dr. H. F. P. Herdman), 273
Defence of Intellectual Freedom, 217
Deformation and the Contact of Surfaces : Elastic (J. F. Archard), 918
Deformation and the Laws of Friction : Elastic (B. Lincoln), 169, *erratum*, 234
Delande, N., and others Qualitative Organic Micro-analysis based on Physical Constants—Identification of Amino-Acids, 906

- Delayed Implantation in the Elephant Seal (L. Gibbney), 590
- Delhi Pillar: The (Dr. J. C. Hudson), 499
- Deming, Prof. Horace G.: General Chemistry, sixth edition, *review* by G. P., 374
- Democracy: Academic Freedom in a, 641
  - Wellsprings of, Guidance for Local Societies (John M. Brewer), 218
- Democracy (Modern): Education and Liberty, the Role of the Schools in a (James Bryant Conant), 468
- Demonstration of Keratin with Aldehyde-Fuchsin (Prof. H. R. Scott), 674
- Dempster, J. P.: Appointed entomologist, Cyprus, 1085
- Denerley, R.: Empirical Research in Industry, 897
- Dénes, G., and others: Structure of Poly-D-glutamic Acid isolated from Capsulated Strains of *B. anthracis*, 508
- Density of Deposited Carbon (A. R. G. Brown, A. R. Hall and W. Watt), 1145
- Density Layering: The Deep Scattering Layer in the Sea—Association with (Dr. H. F. P. Herdman), 275
- Denz, Dr. F. A.: Anticholinesterases, 844
- 2-Deoxy-D-ribose: A New Synthesis of (P. A. J. Gorin and Dr. J. K. N. Jones), 1051
- Deoxypentose Nucleic Acid (Crystalline): Helical Structure of (Dr. M. H. F. Wilkins, Dr. W. E. Seeds, Dr. A. R. Stokes and Dr. H. R. Wilson), 759
- Deoxyribonuclease (Acid and Neutral): Urinary Excretion of, by Rats under Normal and Post-Irradiation Conditions (O. D. Kowlessar, Prof. K. I. Altman and L. H. Hempelmann), 867
- Deoxyribonucleic Acid: Degree of Polymerization of (Dr. Norman G. Anderson), 807
  - Hydration Structure of, and its Physico-Chemical Properties (Dr. Bertil Jacobson), 666
- Deoxyribonucleic Acid (Calf Thymus): Separation of, into Fractions of Different Composition (Prof. Erwin Chargaff, Dr. Charles F. Crampton and Miss Rakoma Lipshitz), 289
- Deoxyribonucleic Acid in the Human Uterine and Vaginal Receptors during the Menstrual Cycle: Variations in the Content of (R. Vokaer, Cl. Gompel and A. Ghilain), 31
- Deoxyribonucleic Acid in Rat Thymocytes: Effect of Ultra-violet Light on (S. J. de Courcy, jun., J. O. Ely and M. H. Ross), 119
- Deoxyribonucleic Acid Content of the Cell Nucleus and Mitosis (Prof. J. Fautrez and N. Fautrez-Firlefyn), 119
- Deoxyribonucleic Acid Content of Erythrocyte Nuclei and Sperms of some Species of Fishes. Arginine and (Dr. R. Vendrely and C. Vendrely), 30
- Deoxyribonucleic Acid Content of the Germinal Vesicle of the Ovocyte in *Fasciola hepatica* (J. Govaert), 302
- Deoxyribonucleic Acids: Heterogeneity of (Dr. Geoffrey L. Brown and M. Watson), 339
- Dependence of Glow to Arc Transitions on Cathode Surface Conditions (Dr. H. Edels), 362
- Depletion of Gamma Isomer of Benzene Hexachloride in Cattle Dipping-Fluids (W. J. Roulston and L. F. Hitchcock), 546
- Deposited Carbon: Density of (A. R. G. Brown, A. R. Hall and W. Watt), 1145
- Deposition of a Coarse Aerosol released from a Low-flying Aircraft (D. Yeo and B. W. Thompson), 168
- Derbyshire, A. N., and Marshall, W. J.: Dyeing and Tanning, 1031
- Derivatives of Umbellulone: Some New (the late Dr. A. E. Gillam and D. G. Moss), 585

Electricity in the Garden (Geoffrey Gerard), *review* by E. W. Golding, 1164
Electricity through Gases (Dr. J. H. Mitchell), 986
Electricity in Horticulture : Applications of, *review* by E. W. Golding, 1164
Electro-Acoustics Congress : International, 189, *corrigendum*, 384
Electrochemical Data (Dr. B. E. Conway), *review* by Dr. J. C. Speakman, 269
Electrochemical Phenomena : Thermodynamics of Irreversible (Prof. S. R. de Groot, P. Mazur and H. A. Tolhoek), 497 ; (Peter H. Kemp), 498
*E*s Potentials : Time-Lag in (Dr. S. D. Elek and E. S. Boatman), 1056
Electrodeposition, International Council for : Conference in London, 754
Electrodynamics : A Simple Formulation of the Unquantized Laws of (Dr. O. Buneman), 859
Electroencephalogram (Human) : The Lambda Wave as a Normal Physiological Phenomenon in the (Dr. Martin Roth and Joy Green), 864

Electroencephalography and Clinical Neurophysiology Third International Congress of, 145
Electrolytes in Organic Solvents : Solutions of (Physical Chemistry Group of the Atomic Energy Research Establishment Symposium on), 149
Electrolytic Etching *p-n* Junction revealed by (Dr. E. Billig and J. J. Dowd), 115
Electrolytic Etching Behaviour of Aluminium : Gas Content and (Dr. F. J. Burger and Dr. V. F. G. Tull), 729
Electromagnetic Fields (Prof. Ernst Weber), Vol 1, Mapping of Fields, *review*, 884
Electron (Conversion-) Angular Correlation of α-Particle and, from the Decay of Ionium (Dr. R. R. Roy and Miss M. L. Goes), 360
Electron Microscope Photographs of Polished Mineral Surfaces (J. Kenyon), 114
Electron Microscope Society of America : Eleventh Annual Meeting, 384
Electron Microscopy : International Conference on, 334
Electron Microscopy, Joint Commission on : Formation of, 334
Electron Optics Recent Research in (Physical Society Symposium on), 61
Electronic Instruments Course on (Atomic Energy Research Establishment, Harwell), 336
Electrons : Specific Ionization produced by Positrons and (R. R. Roy and M. Etienne), 953
Electrons (High-Energy) Irradiation of Polymers by (E. J. Lawton, A. M. Bueche and J. S. Balwit), 76
Electrophoresis : Paper, of Streptomycins (M. C. Foster and G. C. Ashton), 958
  Paper, of Sugars at High Potential Gradients (Dr. D. Gross), 908
Electrophoresis (Paper) : Reduction of Liquid Flow in (M. A. Jermyn and R. Thomas), 728
Electrophoresis in a Strong Centrifugal or Magnetic Field : Separation of Racemic Mixtures by (Prof. Frederick C. Landrum), 499
Elek, Dr. S. D., and Boatman, E. S. : Time-Lag in E_h Potentials, 1056
Element (Essential) : Vanadium as an, for Green Plants (Prof. Daniel I. Arnon and Gunilla Wessel), 1039
Elements : Transmutation of the (British Association for the Advancement of Science, Section B (Chemistry), Discussion on), 606
Elephant Seal Delayed Implantation in the (L. Gibbney), 590
Eley, Dr. D. D. : Solutions of Electrolytes in Organic Solvents, 150
Elkes, Dr. J. Anticholinesterases, 843
Elliott, Dr. A. : Infra-Red Dichroism in Synthetic Polypeptides, 359
Elliott Brothers (London), Ltd. : Appointment of H. C. Pritchard as deputy general manager in charge of science, 797
Ellis, J. : Recent Research in Electron Optics, 61
Ellis, S. C., and Pankhurst, K. G. A. : Dyeing and Tanning, 1031
Elsasser, Prof. W. M. : Magnetic Properties of the Earth's Interior, 786
Ely, J. O., and others : Effect of Ultra-violet Light on Deoxyribonucleic Acid in Rat Thymocytes, 119
Embleton, C. : Awarded a Nature Conservancy Research Studentship in Physiography, 708
Embleton, T. F. W. (Barber, G. J., and) Saw-toothed Wave-forms in Sound, 1057
Embryo (Chicken) : Glycogen in the Dividing Cells of the Liver of the (R. J. O'Connor), 678
Embryogenesis : Activity of the Incretory Centres of *Locustana pardalina* during—Function of the Prothoracic Glands (Dr. Bryn M. Jones), 551
Embryology (Lester George Barth), revised edition, *review*, 1020
  An Introduction to, *review* by Dr. James Needham, 739
Embryology and Experimental Morphology : Conference on, 1084
Embryology and Experimental Morphology, Journal of, 240
Embryonic Development of *Drosophila* : Abnormal, induced by Ultrasonic Treatment (G. G. Selman and S. J. Counce), 503
Embryonic Mouse Tissues separated by a Membrane Filter Morphogenetic Interaction between (Dr. Clifford Grobstein), 869
Empirical Research in Industry (Acton Society Trust and the York Civic Trust Discussion on), 897
Employment and Welfare (Institute of Personnel Management, in collaboration with the Personnel Management Branch of the Ministry of Labour, Residential Study-course on), 336
Emulsions (Nuclear Research) Recovery of Isotopic Boron and Lithium from (M. L. Smith), 1054
Endean, R. : Discovery of Iron in Tunicin-forming Blood Cells of an Ascidian, 123
Endeavour, 612
Endicott, K. M., and Allen, E. M. : Medical Research in the United States, 1172
Endocrinology, Society for : Memoirs of the, 485
Endodermal Origin of the Peritrophic Membrane in some Insects : Occurrence and (D. F. Waterhouse), 676
Endosperm : Chromosome Breakage Experiments with—Sub-chromatid Breakage (L. F. La Cour and A. Rutishauser), 501
Energy Requirements for Cation Transport : Rates of Glycolysis in Human Red Cells in relation to (Ralph E. Bernstein), 911
Engel, Dr. A. von, and Francis, G. : Ionization Phenomena in Gases, 798
Engelmann, T. G. : Biological Rhythms, 943
Engineering : Importance of Titanium and its Alloys in, 608
  Musical (Dr. Harry F. Olson), *review* by Dr. E. G. Richardson, 645
  Scholarships and Fellowships in Science and (National Research Council of Canada), 17
Engineering (Chemical) Careers in (Prof. H. E. Watson), 489
Engineering (Communication) : Harmonics, Sidebands and Transients in (C. Louis Cuccia), *review* by F. Horner, 5
Engineering (Mechanical) An Introduction to the Theory of Control in (R. H. Macmillan), *review* by Prof. J. Greig, 91
Engineering at University College, Dundee, 893
Engineering in the next 2,000 Years (Lord Dudley Gordon), 433
Engineering Aspects of Acoustics, *review* by Dr. E. G. Richardson, 645
Engineering Design : Photoelasticity and, *review* by E. K. Frankl, 926
Engineering Importance : Titanium, a Metal of (Major P. L. Teed), 608
Engineering Industries : The Craftsman in the (D. B. Welbourn), 1088
Engineering Institute of Canada (Institution of Electrical Engineers and the) : Discussion by radio on Technical Arrangements for the Sound and Television Broadcasts of the Coronation Ceremonies on 2nd June 1953, 1129
Engineering Mechanics, *review* by Dr. R. E. D. Bishop, 973
Engineering Production Courses in the University of Birmingham : Post-graduate (Prof. T. U. Matthew), 59
Engineering and Industry : The Utilization of Digital Computing Machines in (British Association for the Advancement of Science, Section G (Engineering), Symposium on), 649
Engineers (Canadian) : Athlone Fellowship Scheme for (Dr. W. Abbott), 758
England during the past Hundred Years : Changes of Outlook in, 1171
England (Eastern) : Domesday Book Records for, *review* by J. R. Hale, 1116
  The Domesday Geography of (Prof. H. C. Darby), *review* by J. R. Hale, 1116
England (South-East) : Temperature and Humidity Gradients in the First 100 m. over (A. C. Best, E. Knighting, R. H. Pedlow and K. Stormonth), 193
England and Wales for the Two Years 1948–49 Statistical Review of (Registrar General), Text, Medical, 1135
England and Wales for the Year 1951 Statistical Review of (Registrar General), Tables, Part I, Medical, 1135
English Education : Friedrich Froebel and (P. Woodham-Smith, J. P. Slight, O. B. Priestman, H. A. Hamilton, N. Isaacs ; edited by Evelyn Lawrence), *review* by Miss P. M. Pickard, 219
English Electric Co., Ltd. : Research Fellowship in Aeronautics awarded to R. G. Anderson, 280
  Perring Scholarship awarded to A. Coull, 280
English-Speaking Union of the United States : Research Fellowships in the United States for Young European Scientific Workers, 570
Engstrom, Prof. A., and others A Comparison between the X-Ray Absorption and Optical Interference Methods for the Mass Determination of Biological Structures, 1041
Entamoeba invadens Bacteria-free (Dr. Max J. Miller), 1192
Enterochromaffin Cells (Mammalian) Detection of 5-Hydroxytryptamine in (Dr. R. Barter and Dr. A. G. Everson Pearse), 810
Enteropneust *Glossobalanus sarniensis* Koehler in Northern Ireland : Occurrence of the (C. Edwards), 343
Entropy Production : Biological Systems and the Principle of Minimum (Dr. D. C. Spanner), 1094
Entwicklungsphysiologie (L. v. Ubisch), *review* by Dr. Joseph Needham, 739
Entwistle, P. P. : Awarded a Nature Conservancy Research Studentship in Zoology, 708
Enzootic Muscular Dystrophy in Beef Cattle : Prevention and Cure of (Dr. K. L. Blaxter and G. A. M. Sharman), 1006
Enzymatic Hydrolysis of Urinary Neutral 17-Ketosteroid Conjugates (S. R. Stitch and L. D. K. Halkerston), 398
Enzymatic Hydrolysis of Xylan (Dr. Henning Sorensen), 305
Enzymatic and Chemical Oxidation of Dimethylphosphoramides to Biologically Active Dimethylphosphoramide Oxides (J. E. Casida, T. C. Allen and M. A. Stahmann), 243
Enzyme (Disproportionating) : *D*-Enzyme, a, in Potato Juice (Prof. Stanley Peat, Dr. W. J. Whelan and W. R. Rees), 158
Enzyme (Receptor-destroying) : Turbidity-reducing Activity of Influenza Virus and, on Sheep Submandibular Mucoid (Dr. J. F. McCrea), 912, 1173
Enzyme (Viral) : Presence of 2-Carboxy-pyrrole in Mucoproteins and its Relation to the (Dr. A. Gottschalk), 808
D-Enzyme, a Disproportionating Enzyme in Potato Juice (Prof. Stanley Peat, Dr. W. J. Whelan and W. R. Rees), 158
Z-Enzyme in Amylolysis (Prof. R. H. Hopkins and Dr. R. Bird), 492 ; (Prof. Stanley Peat and Dr. W. J. Whelan), 494
Enzyme Extract (Plant) : Synthesis of Sucrose by a (J. F. Turner), 1149
Enzyme Formation Terminology of (M. Cohn, Dr. J. Monod, M. R. Pollock, S. Spiegelman and R. Y. Stanier), 1096
Enzyme System (Mammalian Adaptive) Influence of Hypophysectomy and of Adrenocorticotropic Hormone on a (Dr. Irving L. Geschwind and Prof. Choh Hao Li), 732
Enzymes (Hydrolytic) : Transferase Activity of (Dr. R. K. Morton), 65
Enzymes of the Intercalated Discs of Heart Muscle Fibres (Dr. Geoffrey H. Bourne), 588
Enzymic Browning of Apples and Pears Chlorogenic Acid and the (C. Weurman and Dr. T. Swain), 678
Enzymic Content of the Mitochondria Fraction (Prof. C. de Duve, R. Gianetto, P. Appelmans and R. Wattiaux), 1143
Eperythrozoon parvum, a Filterable Blood Parasite of Swine (Earl J. Splitter), 40
Ephemeropteran Nymph : Feeding Mechanism of an (R. Hartland-Rowe), 1109
Ephrussi, Prof. Boris : Nucleo-cytoplasmic Relations in Micro-organisms, *review* by Prof. C. H. Waddington, 784
Epicatechin : 'Leuco-cyanidin' and (Dr. W. G. C. Forsyth), 726
Epigraphy Indian, and South Indian Scripts (C. Sivaramamurti), *review* by M. C. Goswami, 374
Epineurium as a Diffusion Barrier (Hans Joachim Lehmann), 1045
Epithelium (Gland Duct) : 'Lipase' in, and in Mucus-secreting Cells (B. F. Martin), 1048
Equations of Motion for Continuous Matter of Special Relativity in the Lagrange Variables (S. F. B. Tyabji), 1147
Equator of the Sun : Difference of Temperature between Pole and (Dr. A. K. Das and K. D. Abhyankar), 496
Equilibrium between Ethoxide and Hydroxide Ions in Ethanol (Dr. E. F. Caldin and G. Long), 583
Ercker, Lazarus Treatise on Ores and Assaying, translated from the German edition of 1580 by Anneliese Grunhaldt Sisco and Cyril Stanley Smith, *review*, 643
Erdtman, Prof. G. Pollen Morphology and Taxonomy of certain African Plants, 988
Erdtman, Prof. Holger Chemical Structure in relation to Plant Growth-Regulating Activity, 710
Erdtman, Prof. Holger, and Wachtmeister, Carl-Axel Structure of Porphyrilic Acid, 724
Erkelens, P. C. van Quantitative Paper Chromatography of Traces of Metal with the Aid of Radioactive Hydrogen Sulphide, 357
Errors in the Estimation of Serial Correlations (J. A. Pope and Dr. F. H. C. Marriott), 778
Erspamer, Dr. V., and others Detection of 5-Hydroxytryptamine by Paper Chromatography, 357
  Chromaffin Bodies of various Species of Dogfish, 509
Eruption of Mt. Lamington, New Guinea Pozzolanic Activity of Ash produced by the (K. M. Alexander and H. E. Vivian), 1002

Eruptive Prominence of February 26, 1953, and Associated Radio Noise-Burst (Dr. R. K. Das and K. Sethumadhavan), 446 ; Radio Observations at the Time of an Ascending Solar Prominence (R. D. Davies), 447
Erythraean Fishes from the Mediterranean Coast of Israel : New (Dr. A. Ben-Tuvia), 464
Erythrocyte Nuclei and Sperms of some Species of Fishes : Arginine and Deoxyribonucleic Acid Content of (Dr. R. Vendrely and C. Vendrely), 30
Erythrocytes : Budding of, in the South African Clawed Toad (*Xenopus laevis*) after Splenectomy (Marcus Jacobson), 1107
  A Rhesus Monkey with *B* Agglutinogen in the (E. C. Buchi), 873
Erythrocytes of various Species : Some Interrelationships of the, with Plant Agglutinins (Lieut.-Colonel G. W. G. Bird), 401
Erythrocytes labelled with Radioactive *p*-Iodophenylhydroxylamine : Studies with (Dr. Harold Jackson), 80
Erythrocytes of Rabbit Blood : Isolation of Thorium B (Lead)-binding Substance from the (Dr. K. K. Reddi), 202
Escande, Prof. L. : Elected correspondent for the Mechanics Section of the Paris Academy of Sciences, 185
E. coli : Quantitative Aspects of the Indirect Action of X-Radiation at various Concentrations on (C. Biagini), 868
E. coli Mutants : Specific Suppression by Glycine of the Phenotypic Expression of Partially Reverted Glycineless (Barbara E. Wright), 308
Eskarous, Mrs. Josephine K. (Tolba, Dr. M. K., and) : Effect of Five Strains of Fowl-Plague Virus on a Sulphonphthalein Dye, 961
Essay Competition : *Research*, 940 ; *Sunday Times*, 941
Essay Competition on Life in A.D. 2000 (Royal Society of Arts), 985
Essen, Dr. L. : High-Frequency Electrical Measurements, 52
Essential Elements for Green Plants : Vanadium as an (Prof. Daniel I. Arnon and Gunilla Wessel), 1039
Essential Oils (Dr. Ernest Guenther), Vols. 5 and 6, *review* by Dr. E. G. Kellett, 133
Essex, H. E. : At the XIX International Physiological Congress, Montreal, 1073
Esterase Activity (Vitamin A) : Intracellular Distribution of, in Rat Liver (Dr. J. Ganguly and Prof. H. J. Deuel, Jun.), 120
Estermann, Dr. T. : Introduction to Modern Prime Number Theory, *review* by Prof. H. T. H. Piaggio, 137
Esters : Hydrolysis of, by Extracts of Insects (K. A. Lord and Dr. C. Potter), 679
Estimates, Select Committee on : Eighth Report from the, together with Minutes of Evidence taken before Sub-Committee E and Appendices, Session 1952–1953, Schools, 467
  Twelfth Report from the, Session 1952–53, Technical Education, 737
Estimating the Survival-Rate of Anopheline Mosquitoes in Nature : A New Method of (C. C. Draper and G. Davidson), 503
Estimation of Serial Correlations : Errors in the (J. A. Pope and Dr. F. H. C. Marriott), 778
Etching (Electrolytic) : *p-n* Junction revealed by (Dr. E. Billig and J. J. Dowd), 115
Etching Behaviour of Aluminium : Gas Content and Electrolytic (Dr. P. J. Burger and Dr. V. F. G. Tull), 729
Ethanol : Dielectric Relaxation Processes in (F. X. Hassion and Prof. R. H. Cole), 212
  Equilibrium between Ethoxide and Hydroxide Ions in (Dr. E. F. Caldin and G. Long), 583
Ethics : Science and (Most Rev. and Rt. Hon. Cyril F. Garbett), 517
Ethiopia (Southern) : A Naturalist in (R. E. Moreau and E. Milne-Redhead), 388
Ethoxide and Hydroxide Ions in Ethanol : Equilibrium between (Dr. E. F. Caldin and G. Long), 583
Ethyl Alcohol : Polarographic Effect of Carbon Dioxide in Solutions of (Dr. A. A. Vlček), 861
Ethylene Oxide Products in Aqueous Solutions or Dispersions : Quantitative Determination of (Dr. N. Schonfeldt), 820
Etienne, M. (Roy, Dr. R. R., and) : Specific Ionization produced by Positrons and Electrons, 953
Euler, Prof. C. von : Biologically Active Polypeptides, 1074
European Association of Exploration Geophysicists—Paris Meeting (T. C. Richards), 189
  Election of Officers for 1953–54, 191
European Cortina-Ulisse Prize for 1953, 60
European Scientific Workers : Research Fellowships in the United States for Young, 569
Evans, Sir Charles Lovatt : Introduction to Human Physiology, *review*, 4
  Anticholinesterases, 843
Evans, L. P. : Interaction between Surfaces in Close Proximity, 776
Evans, Verney : Chemical Processes and Chemical Engineering Techniques, 711
Evaporation of Water : Effect of Surface Films on the (W. W. Mansfield), 1101
Evenari, Prof. Michael, and others : Factors modifying the influence of Light on Germination, 452
Everest : The Ascent of (Lectures by members of the Everest Expedition, to be given at the Royal Festival Hall), (Royal Geographical Society and the Alpine Club), 146
Everest Expedition : Lectures by members of the (Royal Geographical Society and the Alpine Club), 146
Evolution : The Mutation Theory of (Prof. L. P. Martin), 22
  Wilberforce and Huxley on (D. J. Foskett), 920
Evolution (organic) : Historical Aspects of (Dr. Philip G. Fothergill), *review*, 375
Evolution of the Ovule in Pteridosperms (Prof. John Walton), 436
Evolutionary Process : Fossils and the (Prof. T. Neville George), 431
Ewer, Dr. D. W., and others : Frequency of Moulting in Anura, 408
Ewes (Hill) : Milk Yield of (J. B. Owen), 636
Excavation of a Traverse of Margidunum (Dr. Felix Oswald), 192
Excavations at Margidunum (Miss Joan Liversidge), 192
Excavations at Mycenae (Prof. A. J. B. Wace), 525
Excell, Miss P. M. : Awarded a Silver Jubilee Commemoration Award of the Illuminating Engineering Society, 709
Excellence : Psychological Problems in the Recognition of (Prof. D. W. Harding), 435
Excised Fern Leaves in Sterile Culture : Growth of (Dr. I. M. Sussex and Dr. Taylor A. Steeves), 624
Excretion by Aphids : Amino-Acids in Phloem Sap and their (T. E. Mittler), 207
Executive Development Programme (British Institute of Management), 796
Exhibition of 1851, Royal Commission for the : Awards for 1953, 17
Expectation and Decision in Business Affairs : Uncertainty, (Prof. G. P. Meredith), 701
Expeditions in the Field : The Provisioning of (Nutrition Society and the Royal Geographical Society Symposium on), 974
Expenditure (University) : Control of, 535
Expenditure of Counterpart Funds derived from United States Economic Aid : White Paper of Programme of, 528
Experiment : The Design and Analysis of (M. H. Quenouille), *review*, 785
Experimental Data and Model Structures for the Insulin Molecule (Dr. Barbara W. Low), 1146
Experimental Design in Biology, *review*, 785
Experimental Diabetes : Utilization of Acetate in (Prof. E. Ciaranfi and A. Fonnesu), 961
Experimental Frequency Transmissions from the United Kingdom : *MSF*—New Programme of (National Physical Laboratory), 529
Experimental Ground in relation to Taxonomy : Methods of the (Dr. W. B. Turrill), 233
Experimental Production of Hepatic Necrosis and Fibrosis with Water (Prof. Wm. O. Reinhardt), 915
Exploration by 'Aqualung' : Underwater, *review* by Dr. A. J. Brook, 370
Exploration Geophysicists, European Association of—Paris Meeting (T. C. Richards), 189
  Election of Officers for 1953–54, 191
Explosion : Size Effects in the Initiation and Growth of (Dr. F. P. Bowden and K. Singh), 378
Explosions in Mixtures of Hydrogen, Chlorine and Nitrogen Trichloride (Dr. P. G. Ashmore), 449
Explosions et des chocs : État actuel et valeur de la théorie hydrothermodynamique des (Dr. S. Travers), Première partie et Deuxième partie, *review* by Prof. D. M. Newitt, 699
Explosives (Condensed) : Detonation of (J. Taylor), *review* by Prof. D. M. Newitt, 699
Extra-galactic Origin : An Extended Radio-frequency Source of (R. Hanbury Brown and C. Hazard), 997
Extra-terrestrial Radio Source Cygnus I : Fine Structure of the (R. C. Jennison and M. K. Das Gupta), 996, *erratum*, 1030
Extraction of a Heparin-like Substance from Mast Cell Granules in Mouse Connective Tissue (Dr. K. Kokral), 733
Extracts from Insects : Adrenaline, Noradrenaline and Hydroxytyramine in (Dr. Eric Östlund), 1042
Extracts of Insects : Hydrolysis of Esters by (K. A. Lord and Dr. C. Potter), 679
Eye Movements in connexion with Television Viewing (Dr. Mary P. Lord), 964
Eyles, V. A. : Jean Rey's Pioneer Work on Oxidation, *review*, 1118
Eysenck, Dr. H. J. : The Scientific Study of Personality, *review* by F. V. S., 5

F-REGIONS : Recombination Coefficient in the—a Possible New Process of Ionization of Nitrogen Molecules (R. B. Banerji), 953
Fabiyi, Dr. Akinyele (Punnett, Dr. Thomas, and) : Production of Oxygen from Chloroplast Preparations—Photochemical Oxygen Production from Isolated Algal Chloroplast Fragments, 947
Facchini, U. : Ionization Phenomena in Gases, 799
Factories, Chief Inspector of : Annual Report for 1951, 285
Factory : Some Problems of a (Wilfred Brown), 383
Facts of Life : Mr. Tompkins Learns the (Prof. George Gamow), *review* by W. L. Sumner, 741
Fage, A. : Retirement as superintendent of the Aerodynamics Division of the National Physical Laboratory, 706 ; work of, 706
Fage, Prof. Louis : Address to the Fourteenth International Congress of Zoology, 829
Fairbairn, W. M. : Appointed a lecturer in mathematics at the University of Glasgow, 1030
Fairbrother, Dr. F. : Solutions of Electrolytes in Organic Solvents, 150
Fairgrieve, James : *Death of*, 706 ; *obituary* by Prof. L. Dudley Stamp, 892
Fairweather, Dr. A. : Electrical Insulation, 9
Faith : Science and, *review* by R. Brightman, 557
Faith To-day : Science and (John Baillie, Robert Boyd, Donald Mackay and Douglas Spanner), *review* by R. Brightman, 557
Falk, Dr. J. E. : Appointed by the Royal Society to a Foulerton Research Fellowship at University College Hospital Medical School, London, 185
Falk, Dr. J. E., and others : Porphobilinogen as a Porphyrin Precursor, and Interconversion of Porphyrins, in a Tissue System, 292
Falk, Dr. J. E. (Dresel, Dr. E. I. B., and) : Conversion of δ-Aminolaevulinic Acid to Porphobilinogen in a Tissue System, 1185
Falkland Islands Dependencies Survey, 441
Family Antigens or 'Private' Blood Groups and the Sub-Group of A–A_4 (I. Dunsford), 1059
Fantl, Dr. P., and Hayes, R. A. : Formation of Thromboplastin in Shed Mammalian Blood, 303
Faraday Society : General Discussion on Dyeing and Tanning, 384, 1031
Faraday Society, and others : Report of the Joint Committee on Infra-red Spectra, 795
Farm : Preventive Medicine on the (Prof. E. G. White), 561
  Rats and Mice on the (Ministry of Agriculture and Fisheries, Bulletin No. 30), eighth edition, 335
Farm Livestock : Preventive Medicine among (British Association for the Advancement of Science, Section M (Agriculture), Discussion on), 561
Farmers' Union, National, and others : National Weed Control Conference, 442
Farming (Regional) : History of, in Britain, 985
Farquhar, R. M., and others : A Comparison of Lead Isotope Analysis Techniques, 860
Farquharson, Miss K. R. : Advances in Methods of Studying Clays, 289
Farrington, G. H. : Fundamentals of Automatic Control, *review* by Prof. J. Greig, 91
Fasciola hepatica : Deoxyribonucleic Acid Content of the Germinal Vesicle of the Ovocyte in (J. Govaert), 302
Fasciola hepatica L. : Maturation and Probable Gynogenesis in the Liver Fluke (Dr. Ann R. Sanderson), 110

Fasman, G. D., and others . Structure of Adenylic Acids *a* and *b*, 1184
Fassam, Mrs. Margery : Group Discussion, 800
'Fast' Nerve Fibres in Locusts : 'Slow' and (G. Hoyle), 165
Fats and other Lipids : Progress in the Chemistry of (edited by Prof. R. T. Holman, W. O. Lundberg and T. Malkin), Vol. 1, *review* by Dr. J. A. Lovern, 740
Fatty Acids (C_{18}–C_{34} Saturated Straight-Chain) : A Simple Chromatographic Method for the Determination of the (H. J. Nijkamp), 1102
Fatty Acids (C_{12}–C_{22}) : Analytical Separation of the Methyl Esters of the, by Vapour-Phase Chromatography (F. R. Cropper and A. Heywood), 1101
Fatty Acids in the Skin : Carcinogens and Oxidized (Mary L. C. Bernheim, Prof. Frederick Bernheim and Karl M. Wilbur), 306
Faunas (Marine) . Life-History of, *review* by N. B. Marshall, 644
Faunas (Sea-Shore) : The Maintenance and Spread of (Prof. J. E. Smith), 432
Fautrez, Prof. J., and Fautrez-Firlefyn, N : Deoxyribonucleic Acid Content of the Cell Nucleus and Mitosis, 119
Fautrez, Prof J. (Fautrez-Firlefyn, N., and) Intranuclear Proteins of the Oocytes in *Artemia salina* L., 163
Fautrez-Firlefyn, N., and Fautrez, Prof. J. : Intranuclear Proteins of the Oocytes in *Artemia salina* L., 163
Fautrez-Firlefyn, N. (Fautrez, Prof. J., and) : Deoxyribonucleic Acid Content of the Cell Nucleus and Mitosis, 119
Favarger, P. : Biochemical Problems of Lipids, 574
Fawcett, D. W. : At the XIX International Physiological Congress, Montreal, 1073
Fazekas de St. Groth, Dr. S. : Appointed a member of the governing body of University House, Australian National University, 440
Fazekas de St. Groth, Dr S , and Graham, Miss Doris M. Absence of 'Incomplete' Virus Production in certain Influenza Strains, 1193
Fearnley, Dr. George R. : Fibrinolysis by Adsorption, 544
Feather, Prof. N. : Nuclear Stability Rules, *review* by Prof. S. Devon, 697
Feder, Dr. H. M. : Solutions of Electrolytes in Organic Solvents, 149
Federal Forest Administration in the Federation of Malaya . Report for the Year 1951 (J. P. Edwards), 1090
Federal Funds for Science (National Science Foundation of Washington), 575, 1171
Federal Funds for Scientific Research and Development at Non-profit Institutions 1950–51 and 1951–52 (National Science Foundation, Federal Funds for Science, 1), 575
Federal Funds for Scientific Research and Development for the Fiscal Years 1952 and 1953 (National Science Foundation, Federal Funds for Science, 2), 1171
Federation of British Industries : Report of the Third Conference of Industrial Directors and Managers, 757
  Appointment of Dr. W. Abbott as director of studies in connexion with the Overseas Scholarships Scheme, 1084
Feeding with Aureomycin : *Listeria* Infection in the Guinea Pig caused by (Prof. Paavo Roine, Aune Raitio and Unto Vartiovaara), 767
Feeding Mechanism of the Cichlid Fish, *Tilapia esculenta* Graham (P. H. Greenwood), 207
Feeding Mechanism of an Ephemeropteran Nymph (R. Hartland-Rowe), 1109
Feinberg, Dr. R., and others : A Sealed-off Cathode-Ray Tube with Very High Writing Speed, 1056
Feingold, D , and others Promotion of Infection by Intravenously Administered Polysaccharides, 765
Feldberg, Dr. W. : Anticholinesterases, 842
Felix, Marie, and others : Isolation and Biochemical Function of the Golgi Substances, 161
Fellowship : To be awarded by King's College, Cambridge, 18
  Glaxo Laboratories Research (Granted through the Friends of the Hebrew University to Miss Alisa Tietz), 187
  Nuffield Gerontological Research (Nuffield Foundation), 654
  Ransom, of the Pharmaceutical Society awarded to Keith Henry Palmer, 280
Fellowship in Aeronautics : English Electric Research (Awarded to R. G. Anderson), 280
Fellowship in Chemistry founded by the Blythe Colour Works, Ltd., Cresswell, in the University College of North Staffordshire, for the support of fundamental investigations into inorganic colouring matters, 709
Fellowship in Gerontology : Nuffield Professorial Research (Nuffield Foundation), 654
Fellowship in Metallurgy : Research (Established by the United Steel Companies, Ltd., in the University of Sheffield), 753
Fellowship for Research and Teaching in Animal Husbandry : William McIlrath (Commonwealth Scientific and Industrial Research Organization), 794
Fellowship Awards and Research Grants (United States National Science Foundation), 102
Fellowship Scheme for Canadian Engineers Athlone (Dr. W. Abbott), 758
Fellowship and Scholarships for Arctic or Sub-Arctic Research (McGill University and the Arctic Institute of North America), 1085
Fellowships : Colonial Civil Service (Commonwealth Fund of New York), 612
  Dominion Civil Service (Commonwealth Fund of New York), 612
  Home Civil Service (Commonwealth Fund of New York), 612
  Leverhulme Research (Awards for 1953), 17
  Research, in the United States for Young European Scientific Workers, 569
  Wellcome Pharmaceutical Research (Awards), 280
Fellowships of the State of Victoria, Australia British Memorial Fund (Awards), 59
Fellowships in Biochemistry, Biophysics and Physiology : Post-doctoral (Lalor Foundation), 1085
Fellowships for Research in Chemistry : Ramsay Memorial (Awards), 103
Fellowships in Science and Engineering : Scholarships and (National Research Council of Canada), 17
Fellowships in Statistics : Post-doctoral (University of Chicago), 613
Fellowships for Study and Travel in the United States (Commonwealth Fund of New York), 611
Fenelon, Dr. K. G. : Britain's Food Supplies, *review* by F. Le Gros Clark, 47
Fenner, Prof. Frank Changes in the Mortality-rate due to Myxomatosis in the Australian Wild Rabbit, 228
Ferguson, W. S., and Terry, R. A. : Purines in Grassland Herbage, 346
Ferigle, S. M., and Weber, A. : Potential Constants of Diacetylene, 399
Fermi, Prof. E Elected president for 1953 of the American Physical Society, 338
Fern Leaves in Sterile Culture Growth of Excised (Dr. I. M. Sussex and Dr. Taylor A. Steeves), 624
Fernandes, J. Biochemical Problems of Lipids, 574
Ferrier Lecture of the Royal Society (Sir Francis Walshe), 797
Ferrous Ions Activation of Fumaric Hydrogenase by (K Harrison), 509
Fertility in Tropical Soils . Relation of Witchweed (*Striga*) to (K. Wilson Jones), 128
Fertilization and the Probability of Normal Development : Storage of Unfertilized Rabbit Ova—Subsequent (Dr M. C. Chang), 353
Fertilizer Responses in East Africa (Dr. D W. Duthie), 564
Fertilizers : Organic Manures and ; and the Production and Composition of Food for Man and Animals (Section of Comparative Medicine of the Royal Society of Medicine Discussion on), 11
Fertilizing Capacity of Frozen Human Spermatozoa (Dr. R. G. Bunge and J. K. Sherman), 767
Feshbach, H. Medium-Energy Nuclear Physics, 527
Fibres (Keratin) : Birefringence and Elasticity in (Dr. R. D. B. Fraser), 675, *errata*, 986
Fibres (Polyethylene Terephthalate) . Fine Structures in (A Cobbold, R. de P. Daubeny, K. Deutsch and P. Markey), 806
Fibres (Synthetic) : Chemistry and Physics of (Plastics and Polymer Group of the Society of Chemical Industry Symposium on), 656
Fibres (Wool and Hair) Resistant Membranes from (B. Manogue and M. S. Moss), 806
Fibrinolysis by Adsorption (Dr. George R Fearnley), 544
Fibrosis Experimental Production of Hepatic Necrosis and, with Water (Prof Wm O. Reinhardt), 915
Fibrous Materials : Physics of (Dutch Physical Society Symposium on), 144
Ficq, Mrs. A. (Gavosto, Dr. F., and) : Radioautographic Study of the Localization of Tobacco Mosaic Virus Antigen, 406
Field An Attenuated Strain of the Myxomatosis Virus recovered from the (Dr. R. Mykytowicz), 448
  Birds of the (James Fisher), *review* by L. J. F. Brimble, 324
  The Provisioning of Expeditions in the (Nutrition Society and the Royal Geographical Society Symposium on), 974
Field Crops, Commonwealth Bureau of Pastures and To be transferred to Hurley, Berkshire, and attached to the Grassland Research Station, 58
Field Experimentation with Fruit Trees and other Perennial Plants (S. C. Pearce), *review* by H. D. Patterson, 221
Field Studies, Council for the Promotion of (Royal Meteorological Society in conjunction with the) Vacation Course in Synoptic Meteorology, 655
Field Studies in Urban Areas (Association of Agriculture and the Joint Biology Committee Conference on), 571, 1032
Field-strength Ultra-short-wave, in a Ground-based Radio Duct (R. S. Unwin), 856
Fields : Unto the (D. W. Gillingham), *review* by Sir Stephen Tallents, 928
Fierz-David, Prof. H. E : *Obituary* by Prof. John Read, 523
Fifty Years of Powered Flight (Sir Ben Lockspeiser), 742
Filarial and Malarial Infections in *Anopheles gambiae* : Inter-relations between (Dr. R. C. Muirhead-Thomson), 352
Fildes, Sir Paul . Awarded a Royal Medal for 1953 of the Royal Society, 938, 1021 , work of, 1021
Films : Three-Dimensional (H. Dewhirst), 484
Films (Surface) . Effect of, on the Evaporation of Water (W. W. Mansfield), 1101
  The Physical Chemistry of (Prof. William D. Harkins), *review* by Dr. James Bell, 828
Filterable Blood Parasite of Swine : *Eperythrozoon parvum*, a (Earl J. Splitter), 40
Financing Higher Education in the United States (John D. Millett), *review* by Sir Hector Hetherington, 470
Finden, H. J. High-Frequency Electrical Measurements, 53
Findenegg, Dr. L. Awarded a Naumann Medal of the International Association of Limnology, 889
Finding Out in Flying : The Fun of (Sir Leonard Bairstow), 1030
Findlay, Alexander The Phase Rule and its Applications, ninth edition, by Prof A. N Campbell and Prof. N. O. Smith, *review* by G. F., 473
Finean, J. B. : Biochemical Problems of Lipids, 573
Finer, Prof. S. E. The Life and Times of Sir Edwin Chadwick, *review* by Prof. T. S. Simey, 421
Finite Sources : A Macroscopic Theory of Interference and Diffraction of Light from (Dr. E. Wolf), 535
Fink, Prof. Colin G. . *Death* of, 938
Finlay, Ian : Museums and the Public, 107
Finney, Dr. D. J. : Statistical Method in Biological Assay, *review* by Dr. J. O. Irwin, 925
Fischer, Prof. P.-H. . Gasteropodes excavateurs de Roches littorales, 830
Fish (Marine) Relation of Chemical Structure to Irritant Responses in (Prof. Robert W. Hiatt, Prof. John J. Naughton and Prof. Donald C. Matthews), 904
Fish (Cichlid), *Tilapia esculenta* Graham : Feeding Mechanism of the (P. H. Greenwood), 207
Fish Culture Methods for *Tilapia* in East Africa . New (J. M. Brown and Dr. Vernon D. van Someren), 330
Fisher, James Birds of the Field, *review* by L. J. F. Brimble, 324
Fisher, L. H. : Ionization Phenomena in Gases, 798
Fisheries Hydrography in relation to (Dr. John B. Tait), *review* by David Vaux, 179
Fisheries Laboratory : New, Burnham-on-Crouch (Dr. H. A. Cole), 790
Fisheries Research Hydrography in, *review* by David Vaux, 179
Fisheries Research Stations : Visitors' Tables at Colonial (Dr. C. F. Hickling), 885
Fisheries Research Vessel *Alister Hardy* of the Fisheries Research Unit, University of Hong Kong, 1170
Fishery . A Method for computing the Optimum Size-Limit for a (K. Radway Allen), 210
Fishery Products in the United Kingdom and their Utilization : A Survey of Agricultural, Forestry and (Development Commission), 574

Fishes: Arginine and Deoxyribonucleic Acid Content of Erythrocyte Nuclei and Sperms of some Species of (Dr. R. Vendrely and C. Vendrely), 30
  New Erythrean, from the Mediterranean Coast of Israel (Dr. A. Ben-Tuvia), 464
Fishes of the Californian Coast: Common Ocean (Phil M. Roedel), *review*, 1069
Fisica, Società Italiana di, and others: Conference on Optics and Microwaves, 102
Fission-Product Radiation: Use of (Chemistry Division of the Atomic Energy Research Establishment Symposium on), 147
Fitter, R. S. R.: Birds of Town and Village, *review* by L. J. F. Brimble, 324
  Field Studies in Urban Areas, 1032
Fixation of Radioactive Colchicine by Ehrlich Ascites Carcinoma Cells (A. Back and E. J. Walaszek), 202
Flames: Eddies in Turbulent Jet Diffusion (Prof. M. W. Thring), 634
Flames brought mechanically into Rotational Motion: Magnetic Fields measured within (P. Schilling and Prof. W. Lochte-Holtgreven), 1054
Flavones: Identification of, by the Ultra-Violet Absorption Spectra of their Ions (G. H. Mansfield, Dr. T. Swain and C. G. Nordström), 23
Flavonoids in *Chlamydomonas eugametos*: Biogenesis of (Prof. A. J. Birch, F. W. Donovan and Dr. F. Moewus), 902
Fleischer, Dr. M.: Elected president of the Commission on Geochemical Localization of the Elements of the International Union of Chemistry, 659
Fleming, J. F.: Appointed lecturer in civil engineering in the University of Sheffield, 146
Flemish Academy of Sciences, Royal: Colloquium on Biochemical Problems of Lipids, 573
Fletcher, Dr. H. R.: Plants of the Bible, *review*, 1162
Flight (Powered): Fifty Years of (Sir Ben Lockspeiser), 742
  Jubilee of, 1082
Flight Muscle Autolysis and Reproduction in Aphids (Bruce Johnson), 813
Flinn, R. A. (Wallace, Dr. W. E., and): Schottky Defects in Solid Solutions, 681
Flood Control and Water Conservation, 823
Floods: North Sea (Institution of Civil Engineers Conference on), 1030
  River, in Great Britain, 263
Flora of Britain: The Changing (edited by J. E. Lousley), 708
Flora of Guatemala (P. C. Standley and J. A. Steyermark), 144
Floras: Tertiary, 1090
Flore d'Afrique Tropicale, Association pour l'Étude Taxonomique de la: Second Plenary Meeting, 987
Florissant Beds, Colorado: Fossil Plants of the (Harry D. MacGinitie), 1090
Flow of Fluids: Application of a New Adsorption Method in the Study of (S. Končar-Djurdjević), 858
Flow of Glaciers (Dr. M. F. Perutz), 929
Flow of Granular Materials such as Sand: Method of Analysing (J. Gittus), 364
Flow of Polycrystalline Ice: Rate of (J. W. Glen), 721
Flow Birefringence of Bovine Cervical Secretions: Ultra-Violet Absorption Spectra and (F. A. Glover), 255
Flower Scent: Diacetyl as a (Miss Jeane T. de Vries), 412
Flowering: Acceleration of, in partially Vernalized Grain of Petkus Winter Rye by subsequent Treatment at High Temperature (D. J. C. Friend and Prof. F. G. Gregory), 667
Flowers, B. H.: Structure of the Atomic Nucleus, 486
Flowers of the Wood (F. M. Day), *review* by L. J. F. Brimble, 324
Flowers and Shrubs: A New Agricultural Research Institute—Glasshouse Crops, Mushrooms and Outdoor (Dr. E. E. Cheesman), 140
Floyd, Horace M., and others: *Folin-Wu* Prepared Blood-Group Specific Substance A, 123
Fluid Dynamics: Essentials of (Prof. Ludwig Prandtl), authorized translation, *review*, 600
  Theory and Applications of, *review*, 600
Fluids: Application of a New Adsorption Method in the Study of Flow of (S. Končar-Djurdjević), 858
  The Molecular Theory of (Prof. Herbert S. Green), *review* by Dr. J. G. Oldroyd, 265
Fluorescence Test for Serotonin and other Tryptamines (Dr. John B. Jepson and B. J. Stevens), 772
Fluoridation of Water, 1083
Fluorine in the Human Skeleton (Prof. John Read), 1156
Fluorine Compounds: Toxic (Dr. F. L. M. Pattison), 1139
Fluorine Tests in Australia on the Keilor Skull and a Tertiary Marsupial (Edmund D. Gill), 409
Fluorspar: Colour Bands in (Prof. K. Przibram), 860
Fly: Motor Responses evoked by the Dorsal Ocelli of *Sarcophaga aldrichi* Parker, and the Orientation of the, to Plane Polarized Light (Dr. W. G. Wellington), 1177
Fly (The Frit): Action of Insecticides on a Stem Borer of Oats— (P. T. Walker), 916
Flying: The Fun of Finding Out in (Sir Leonard Bairstow), 1030
Flying Locust Swarms: Some Recent Developments in the Use of Aircraft against (Dr. R. C. Rainey and H. J. Sayer), 224
Flying Saucers (Prof. Donald H. Menzel), *review* by Dr. C. E. P. Brooks, 220; (C. C. Wylie), 655
Foam: Sea (Dr. A. J. Southward), 1059
Foetal and Sickle-cell Haemoglobins in Human Anaemias: Detection of (Dr. G. H. Beaven and Dr. J. C. White), 1006
Foetus 28 Weeks Old (Human): Formation of Neurofibrils in the Brain of a (M. C. H. Dodgson), 404
Folin-Wu Prepared Blood-Group Specific Substance A (Dr. Earl B. Gerheim, Horace M. Floyd, Andre M. Wertzenhoffer, James Okubo and Bernard Spring), 123
Folkow, Dr. B.: Haemodynamics of Small Vessels, 1073
Folley, Dr. S. J.: Biochemical Problems of Lipids, 574
  Promoted a Deputy Chief Scientific Officer in the Scientific Civil Service, 657
  Appointed a visiting professor in the Collège de France, Paris, 942
Fonnesu, A. (Ciaranfi, Prof. E., and): Utilization of Acetate in Experimental Diabetes, 961
Food for Man and Animals: Organic Manures and Fertilizers and the Production and Composition of (Section of Comparative Medicine of the Royal Society of Medicine Discussion on), 11
Food for the World, *review*, 371
Food and the Future: The White Man's Dilemma—(Lord Boyd-Orr, with the co-operation of David Lubbock), *review*, 371
Food Industry: Chemical Engineering in the (Chemical Engineering Group and the Food Group of the Society of Chemical Industry Conference on), 1131
Food Supplement: *Bact. coli* as a (R. S. Roberts), 351
Food Supplies: Britain's (Dr. K. G. Fenelon), *review* by F. Le Gros Clark, 47
Food Supply and Consumption in Great Britain, *review* by F. Le Gros Clark, 47

Geballe, R. : Ionization Phenomena in Gases, 799
Geddes, A. : Appointed a lecturer in mathematics at the University of Glasgow, 1030
Geesteranus, Dr. R. A. Maas Lichens of Kenya, 988
Geiger, Ruth S. · At the XIX International Physiological Congress, Montreal, 1072
Gels (Nitrocellulose–Water) : Dielectric Properties of (Dr. Hugo Fricke), 1106
Gene : A Human Blood-Group, Intermediate between *M* and *N* (L. Dunsford, Elizabeth W. Ikin and Dr. A. E. Mourant), 688
General Electric Co., Ltd. : Appointment of O. W. Humphreys and A. L. G. Lindley to the board of directors, 101
General Post Office : First Report of the Television Advisory Committee, 337
Generation of Weak Shock Waves (Dr. V. Timbrell), 540
Genetic Pathways A Relationship between Dominance, Phenotypic Stability and Variability, and a Theory of Alternative (Dr. D. Lewis), 1136
Genetical Aspects of Plant Disease (British Mycological Society Conference on), 989
Genetics Ninth International Congress of (Dr. G. Pontecorvo), 756, 840
Genetics of Garden Plants (M. B. Crane and W. J. C. Lawrence), fourth edition, *review* by Prof. S. C. Harland, 7
Genetics and Plant Pathology (Prof. K. Mather), 989
Geochemistry (International Union of Chemistry Symposium on), 659
  A Fundamental Law of (Dr. L. H. Ahrens), 1148
Geodesy and Geophysics, Irish National Committee for, 142

Geodesy and Geophysics, National Committee for : Appointment of T. O. Muireadhaigh as chairman, 280
Geographer as Humanist (Prof. R. H. Kinvig), 432
Geographical Association : Annual Conference, 1084
Geographical Exploration To-day (Lectures arranged by the Department of Extra Mural Studies of the University of London), 526
Geographical Society, Royal : Statue of David Livingstone unveiled by Oliver Lyttelton, 795
Geographical Society, Royal, and the Alpine Club : Lectures by members of the Everest Expedition, 146
Geographical Society, Royal (Nutrition Society and the) : Symposium on the Provisioning of Expeditions in the Field, 974
Géographie humaine : Les fondements de la (Prof. Max Sorre), Tome 3, L'Habitat, conclusion générale, *review* by Prof. L. Dudley Stamp, 422
Geography of Eastern England : The Domesday (Prof. H. C. Darby), *review* by J. R. Hale, 1116
Geological Data : A Suggested Alternative to the Correlation Coefficient for testing the Significance of Agreement between Pairs of Time Series, and its Application to (T. P. Burnaby), 210
Geological Structure of the Russian Platform (Dr. S. I. Tomkeieff), 751
Geological Survey : Investigations by Boring carried out within the Past Year by the (Dr. W. J. Pugh), 12
Geological Survey, Federation of Malaya : Appointment of H. Service as director, 60
  Appointment of H. E. F. Savage as deputy director, 753
Geological Survey, Gold Coast : Appointment of R. J. Murray as petrologist, 1085
Geological Survey Boring in Great Britain (Dr. W. J. Pugh), 12
Geological Survey Department, Gold Coast : Appointment of A. Huddlestone as deputy director, 60
Geological Survey Department, Uganda : Appointment of H. Wright as superintendent, rural water supplies, 60
Geology at the University College of North Staffordshire, 750
Geology and Mineralogy at Trinity College, Dublin, 1082
Geomagnetic Activity and the Sunspot Cycle (Dr. R. Ananthakrishnan), 854
Geometrie ebener Kurven : Einführung in die freie (Prof. Dr. Louis Locher-Ernst), *review* by Prof. H. T. H. Piaggio, 269
Geometry : Algebraic Projective (Prof. J. G. Semple and G. T. Kneebone), *review* by Prof. H. T. H. Piaggio, 741
Geophysical Interpretation of Irregularities in the Rotation of the Earth : On the (Walter Munk and Roger Revelle), 707
Geophysical Mixture : A, *review* by Sir Edward Bullard, 321
Geophysical Service, Inc. : Technicolor Film entitled Make no Mistake, 191
Geophysical Year 1957–58 : The International (Prof. Sydney Chapman), 327
Geophysics : Advances in (edited by H. E. Landsberg), Vol. 1, *review* by Sir Edward Bullard, 321
  Chree's Influence on Present-day (Prof. J. Bartels), 442
  Half a Century in (Sir Harold Jeffreys), 430
  Scholarship in Meteorology or (Italian Society of Geophysics and Meteorology), 571
George, Prof. T. Neville : Fossils and the Evolutionary Process, 431
Georgi, Prof. F. : Biological Rhythms, 943
Gerard, Geoffrey : Electricity in the Garden, *review* by E. W. Golding, 1164
Gerheim, Dr. Earl B., and others : *Folin-Wu* Prepared Blood-Group Specific Substance A, 123
Gerjuoy, E. : Medium-Energy Nuclear Physics, 527
Germ-Cells of *Vaginula maculata* (Male) : Golgi Bodies in the (Dr. M. D. L. Srivastava), 689 ; (Dr. John R. Baker), 690
Germain-Jones, D. T. : Elected president of the European Association of Exploration Geophysicists for 1953–54, 191
German Geological Society : Leopold von Buch Medal awarded to Dr. W. J. Arkell, 709
German Research Institute, Berlin-Dahlem : Now joined to the Max Planck Association for the Advancement of Science, 334
Germinal Vesicle of the Ovocyte in *Fasciola hepatica* : Deoxyribonucleic Acid Content of the (J. Govaert), 302
Germination : Factors modifying the Influence of Light on (Prof. Michael Evenari, Dr. Gert Neumann and Dr. Gabriel Stein), 452
Gerontological Research Fellowship (Nuffield Foundation), 654
Gerontology : Nuffield Professorial Research Fellowship in (Nuffield Foundation), 654
Gerontology, International Association of : Third Congress, 1131
Gerrard, Dr. W. (Cade, J. A., and) : Action of Thionyl Chloride on Carboxylic Acids in the presence of Pyridine, 29
Gerritzen, F. : Biological Rhythms, 943
Geschwind, Dr. Irving I., and Li, Prof. Choh Hao : Influence of Hypophysectomy and of Adrenocorticotropic Hormone on a Mammalian Adaptive Enzyme System, 732
Gething, P. A. : Appointed senior agricultural officer, Federation of Malaya, 60
Ghilain, A., and others : Variations in the Content of Deoxyribonucleic Acid in the Human Uterine and Vaginal Receptors during the Menstrual Cycle, 31
Gianetto, R., and others : Enzymic Content of the Mitochondria Fraction, 1143
Gibboney, L. : Delayed Implantation in the Elephant Seal, 590
Gibbs, Prof. R. Darnley (Towers, G. H. N., and) : Lignin Chemistry and the Taxonomy of Higher Plants, 25
Gibbs, Dr. W. J. : Analysers and Computers for Electrical Systems, 614
Gibson, Prof. R. E. : Science and the Arts, 707
Gibson, Dr. W. M. : Appointed a lecturer in physics at Queen's University, Belfast, 60
Gill, Edmund D. : Fluorine Tests in Australia on the Keilor Skull and a Tertiary Marsupial, 409
Gill, Dr. W. D. : Appointed to the chair of geology and mineralogy in Trinity College, Dublin, 1082 ; work of, 1082
Gillam, the late Dr. A. E., and Moss, D. G. : Some New Derivatives of Umbellulone, 585
Gillespie, J. J. : Group Discussion, 800
Gillett, J. B. : Relation between the Highland Flora of Ethiopia and that of Kenya Colony, 988
Gillingham, D. W. : Unto the Fields, *review* by Sir Stephen Tallents, 928
Giltrow, J. (Curzon, Dr. G., and) : A Chromatographic Colour Reagent for a Group of Amino-Acids, 356
Ginsberg, A. S. : Impurity Phenomena, 386
Ginsburg, David (Loffler, Alfred, and) : A New Synthesis of Carbazoles, 820
Ginzton, Prof. E. L. : High-Frequency Electrical Measurements, 53
Gisborne, J. H. : Appointed principal agricultural officer, Nigeria, 234
Gittus, J. : Method of Analysing Flow of Granular Materials such as Sand, 364
Glaciers : The Flow of (Dr. M. F. Perutz), 929
Gland Duct Epithelium : 'Lipase' in, and in Mucus-secreting Cells (B. F. Martin), 1048
Glands (Prothoracic) : Activity of the Incretory Centres of *Locustana pardalina* during Embryogenesis—Function of the (Dr. Bryn M. Jones), 551
Glass : Third International Congress on, 287
Glass, International Commission on : Annual Meeting, 287
  Election of Dr. B. P. Dudding as president, 287
  Election of Prof. W. E. S. Turner as honorary president, 287
Glass Rod : Transverse Cracks in (E. R. W. Jones and P. L. Pratt), 463
Glasshouse Crops, Mushrooms and Outdoor Flowers and Shrubs : A New Agricultural Research Institute— (Dr. E. E. Cheesman), 140
Glasshouse Tomatoes : Combined Hormone-Fungicide Sprays for Control of *Botrytis* Fruit-Rot in (F. J. Newhook and R. M. Davison), 351
Glassware for the Laboratory (Quickfit and Quartz, Ltd.), 754, (James A. Jobling and Co., Ltd.), 754
Glaxo Laboratories : Research Fellowship awarded to Miss Alisa Tietz, 187
Gleen, Dr. H. : A Modified Pettenkoffer Tube, 817
Glen, J. W. : Rate of Flow of Polycrystalline Ice, 721
Glenny, A. T. : Awarded the Jenner Medal of the Royal Society of Medicine, 794 ; work of, 794
Glossobalanus sarniensis Koehler in Northern Ireland : Occurrence of the Enteropneust (C. Edwards), 343
Glover, F. A. : Ultra-Violet Absorption Spectra and Flow Birefringence of Bovine Cervical Secretions, 255
Glover, R. : The Musk-Ox, 752
Glow to Arc Transitions : Dependence of, on Cathode Surface Conditions (Dr. H. Edels), 362
Glückauf, Dr. E. : Solutions of Electrolytes in Organic Solvents, 149
Gluckman, Dr. A. : Third Douglas Lea Memorial Lecture of the Hospital Physicists' Association, 442
Glucose Content of Leaf : Resistance to a Plant Disease associated with High (L. C. Hughes and H. D. Fowler), 316
Glucose Oxidation in *Asterococcus mycoides* : Pathway for (A. W. Rodwell and E. Shirley Rodwell), 254
Glucosides from Phenols in Locusts : Formation of (Celia M. Myers and Dr. J. N. Smith), 32
Glutamotransferase in the Chick Embryo during Incubation (D. Rudnick, P. Mela and Dr. H. Waelsch), 253
Glutathione and Cysteinylglycine : Isolation of a Mixed Disulphide of, from a Partial Hydrolysate of Glutathione (Dr. Eskil Wikberg), 398
Glycerine : Production and Uses of, *review* by Prof. T. P. Hilditch, 1066
Glycerol (edited by Carl S. Miner and N. N. Dalton), *review* by Prof. T. P. Hilditch, 1066
Gylcerophosphoryl Choline as a Precursor of Free Choline in Mammalian Semen (Dr. Frank Lundquist), 587
Glycine : Specific Suppression by, of the Phenotypic Expression of Partially Reverted Glycineless *E. coli* Mutants (Barbara E. Wright), 308
Gylcineless *E. coli* Mutants : Specific Suppression by Glycine of the Phenotypic Expression of Partially Reverted (Barbara E. Wright), 308
Glycogen in the Dividing Cells of the Liver of the Chicken Embryo (R. J. O'Connor), 678
Glycolysis in Human Red Cells : Rates of, in relation to Energy Requirements for Cation Transport (Ralph E. Bernstein), 911
Goblet Cells of the Small Intestine : Mucus-producing (H. Moe), 309
Godfrey, J. : Awarded a Nature Conservancy Research Studentship in Zoology, 708
Goebel, Walther F. (Jesaitis, Margeris A., and) : Mechanism of Phage Action, 622
Goes, Miss M. L. (Roy, Dr. R. R., and) : Angular Correlation of α-Particle and Conversion-Electron from the Decay of Ionium, 360
Gold Coast : Sorghum Midge and Resistant Varieties in the (J. Bowden and R. A. Neve), 551
Gold Medal of the Royal Aeronautical Society awarded to E. F. Relf, 381
Goldacre, R. J. : Relation between Dye Uptake and Cytoplasmic Streaming in *Amoeba proteus*, 593
Goldblum, J. (Hestrin, Dr. Shlomo, and) : Levanpolyase, 1046
Goldemberg, J. (Katz, Prof. L., and) : Isomeric States of Molybdenum-93, 723
Golding, E. W. : Applications of Electricity in Horticulture, *review*, 1164
Goldsmith, B. J. (Hough, J. M., and) : Use of High Contrast in the Photography of Interference Fringes, 1105
Goldsmith, George J. (Bleuler, Prof. Ernst, and) : Experimental Nucleonics, *review* by R. L. Fortescue, 1163
Goldstein, M. S. : At the XIX International Physiological Congress, Montreal, 1073
Goldsworthy, P. R. : Appointed agricultural officer, Nigeria, 1085
'Golgi Apparatus', 'Golgi Body' and 'Golgi Substance' : The Expressions (Dr. John R. Baker), 617
Golgi Bodies in the Male Germ-Cells of *Vaginula maculata* (Dr. M. D. L. Srivastava), 689 ; (Dr. John R. Baker), 690
'Golgi Body' and 'Golgi Substance' : The Expressions 'Golgi Apparatus', (Dr. John R. Baker), 617
'Golgi Substance' : The Expressions 'Golgi Apparatus', 'Golgi Body' and (Dr. John R. Baker), 617
Golgi Substances : Isolation and Biochemical Function of the (Dr. Walter C. Schneider, A. J. Dalton, Edward L. Kuff and Marie Felix), 161
Gompel, Cl., and others : Variations in the Content of Deoxyribonucleic Acid in the Human Uterine and Vaginal Receptors during the Menstrual Cycle, 31
Good, Dr. I. J. : The Logic, Philosophy and Psychology of Business Decision-making under Uncertainty, 702

Grinsted, H. Awarded the Silver Medal of the Royal Aeronautical Society, 381
Grobstein, Dr. Clifford : Morphogenetic Interaction between Embryonic Mouse Tissues separated by a Membrane Filter, 869
Groot, Prof S. R. de, and others : Thermodynamics of Irreversible Electrochemical Phenomena, 497
Gross, Dr. D. Paper Electrophoresis of Sugars at High Potential Gradients, 908
Gross, J. : Mechanism of Formation of the Thyroid Hormone, 1074
Ground . Earthquake Damage and the Nature of the (Kiyoshi Kanai, Teiji Tanaka and Tomisaburo Suzuki), 751
Ground-based Radio Duct : Ultra-short-wave Field-strength in a (R. S. Unwin), 856
Grounds, A. : Appointed an honorary lecturer in mineral dressing and coal preparation in the University of Leeds, 895
Group Discussion (Special issue of the *Health Education Journal* devoted to the subject of), 799
Grove, Dr. W. P. : Use of Fission-Product Radiation, 148
Growth of Excised Fern Leaves in Sterile Culture (Dr. I. M. Sussex and Dr. Taylor A. Steeves), 624
Growth of Explosion Size Effects in the Initiation and (Dr F. P. Bowden and K. Singh), 378
Growth of Garden Beet : Effects of Close Spacing on the (Dr. L. G. G. Warne), 506
Growth of Isolated Oat Embryos : Amino-Acids and the (G. P. Harris), 1003
Growth of Natural Knowledge (Dr. E. D. Adrian), 1023

Growth in Petioles: Secondary; and the Partial-Shoot Theory of the Leaf (Dr. B. Samantarai and T. Kabi), 37
Growth of the Radicle after Treatment of Tomato Seed with Bromine Water: Stimulation of the (William G. Boll), 963
Growth of the Silkworm, *Bombyx mori* L.: Effect of Antibiotics on the (M. R. Venkatachala Murthy and M. Sreenivasaya), 684
Growth of a Variant of *Bacillus subtilis*: Effect of Citric Acid on the (Prof. J. M. Wiame and S. Bourgeois), 310
Growth Cycle of Ectromelia Virus in Mouse Liver (G. J. V. Nossal and Prof. P. M. de Burgh), 671
Growth Factor: Coconut Milk (F. C. Steward and S. M. Caplin), 102
    An Unidentified, for Yeast and Hyperthyroid Rats (Dr. E. Tria and Dr. O. Barnabei), 203
Growth-factors of Mice: Orotic Acid as One of the (Katashi Makino, Takeo Kinoshita, Kiyoo Satoh and Tadashi Sasaki), 914
Growth-Regulating Substances Plant, *review* by Prof. R. L. Wain, 1117
Growth Response of Tree Seedlings to Mycorrhizal Mycelia in the Absence of a Mycorrhizal Association (Dr. Ida Levisohn), 316
Grüneberg, Dr. H.: Race Crossing in Man, *review*, 137
Guar and Cucurbit Plants in Bihar: Ozonium Wilt of (J. N. Mishra), 209
Guatemala: Flora of (P. C. Standley and J. A. Steyermark), 144
    Orchids of (Oakes Ames and Donovan Stewart Correll), 144
Guenther, Dr. Ernest: The Essential Oils, Vols. 5 and 6, *review* by Dr. E. G. Kellett, 133
Guggenheimer, K. M.: Appointed lecturer in natural philosophy at the University of Glasgow, 1030
Gughé Highlands (Southern Ethiopia), 1948–49: Journey to the—Biogeographical Research at High Altitudes (Dr. Hugh Scott), 388
Guided Missiles at Woomera: Work on, 893
Guiler, Dr. Eric R.: Distribution of the Brush Possum in Tasmania, 1091
Guinea Pig: *Listeria* Infection in the, caused by Feeding with Aureomycin (Prof. Paavo Roine, Anna Raitio and Unto Vartiovaara), 767
    Susceptibility of the, to Pharmacological Factors from its own Serum (Dr. M. E. Mackay, Dr. A. A. Miles, Dr. M. Schachter and Dr. D. L. Wilhelm), 714
Gullón, E.: Sunspot Observations in Spain, 383
Gummosis: Causes of Coconut Nutfall and (Dr. F. L. Vanderplank), 315
Gunn, Prof. J. C.: High-Energy Physics, *review*, 472
Gurr, George T.: Biological Staining Methods, fifth edition, *review*, 269
Gush, Herbert (Jones, A. Vallance, and): Spectrum of the Night Sky in the Range 1·2–2μ, 496
Gussmann, —.: Empirical Research in Industry, 898
Gustavson, K. H. Dyeing and Tanning, 1031
Guthrie, Dr Douglas (edited by Stewart, Dr. C. P., and): Lind's Treatise on Scurvy, a Bicentenary Volume containing a reprint of the first edition of A Treatise of the Scurvy by James Lind, with additional Notes, 50
Guy's Hospital Medical School Title of professor emeritus of physics in the University of London conferred on Prof. Gilbert Stead, 234
Guzman, Gines: Awarded a Ramsay Memorial Fellowship for research in Chemistry, 103
Gynogenesis (Probable): Maturation and, in the Liver Fluke, *Fasciola hepatica* L. (Dr. Ann R. Sanderson), 110
Gysel, Dr. H.: Prozenttabellen organischer Verbindungen (Tables of Percentage Composition of Organic Compounds), C—H—O, C—H—N, C—H—O—N, C—H; C—H—S, C—H—O—S, C—H—N—S, C—H—O—N—S, *review* by Prof. J. W. Cook, 48

HABBERJAM, G. M.: At the fourth meeting of the European Association of Exploration Geophysicists, 190
Haddow, Prof. Alex.: Obituary of Prof William H. Woglom, 1170
Hadley, C. J. Appointed assistant conservator of forests, British Solomon Islands Protectorate, 1085
Haeffner, E. A Method of Changing the Isotope Abundance in Mercury, 775
Hæmagglutinin Anti-*N* in Plant Seeds (F. Ottensooser and K. Silberschmidt), 914
Hæmoglobin in Fungi—Occurrence of Hæmoglobin in Yeast and the supposed Stabilization of the Oxygenated Cytochrome Oxidase (Prof. D. Keilin), 390; Hæmoglobin in Moulds, *Neurospora crassa* and *Penicillium notatum* (Prof. D. Keilin and Dr. A. Tissières), 393
Hæmoglobin in Protozoa (Prof. D. Keilin and Dr. J. F. Ryley), 451, *erratum*, 526
Hæmoglobins (Foetal and Sickle-cell) Detection of, in Human Anæmias (Dr. G. H. Beaven and Dr. J. C. White), 1006
Hæmolytic Disease of New-born Pigs caused by Iso-Immunization of Pregnancy (J. C. Buxton and N. H. Brooksbank), 355
Haigh, Dr. C. P.: An Analysis for Deuterium based on the Photoneutron Effect, 359
Haine, M. E.: Recent Research in Electron Optics, 61
Hair (Animal): Resistant Components of the Cortex of (E. H. Mercer), 164
Hair Fibres: Resistant Membranes from Wool and (B. Manogue and M. S. Moss), 806
Hair and Fur: Exhibition to illustrate the Sources and Biology of (Transferred from the Cranbrook Institute of Science, U.S.A., to Britain for circulation by the Museums Association), 144
Halberg, F.: Biological Rhythms, 943
Halcrow, James G.: Observations on the Anal Papillæ of *Culex* (*culex*) *fatigans* Wiedemann, 1156
Hale, Dr. C. W., and others: Hydrophilic Penicillins, produced by *Penicillium chrysogenum*, 545
Hale, J. R.: Domesday Book Records for Eastern England, *review*, 1116
Half-life of Potassium-40: Specific γ-Activity, the Branching Ratio and (Dr. P. R. J. Burch), 361
Half-value Periods for the Decay of Aluminium-26, Aluminium-25 and Nitrogen-13 (J. L. W. Churchill, W. M. Jones and S. E. Hunt), 460
Halkerston, I. D. K. (Stitch, S. R., and): Enzymatic Hydrolysis of Urinary Neutral 17-Ketosteroid Conjugates, 398
Hall, A. R., and others: Density of Deposited Carbon, 1145
Hall, Dr. D. A.: Awarded a Nuffield Gerontological Research Fellowship, 654
Hall, Dr. D. A., and others: Thermal Contraction of Collagen and its Dissolution with Elastase, 1100
Hall, P. K.: Awarded a postgraduate research scholarship by Courtaulds' Scientific and Educational Trust Fund, 383
Hall, G. L.: High-Frequency Electrical Measurements, 53
Hall, H. S., and others: Milk Pasteurization, Planning, Plant Operation and Control, 335
Hall, Dr. R. N.: Impurity Phenomena, 386
Hall (Wilfred) Telescope, 186
Hallows, H. B.: Awarded a postgraduate research scholarship by Courtaulds' Scientific and Educational Trust Fund, 383
Hallsworth, Prof. H. M.: *Death of*, 524
Halogenation of Aromatic Compounds by Silver Benzoate–Halogen Complexes: Phenylation, Benzoyloxylation and (Dr. D. Bryce-Smith), 863
Halophilic Bacterium: Aspartate-Glutamate Transaminase in a Red (J. Robinson and H. Katznelson), 672
Halperin, L.: Elected a Fellow of the Royal Society of Canada, 1176
Halvorson, Dr. H. O.: Adaptation in Micro-organisms, 236
Ham, Prof. Arthur Worth: Histology, second edition, *review* by Dr. G. H. Bourne, 1019
Hambler, David J.: Prochromosomes and Supernumerary Chromosomes in *Rhinanthus minor* Ehrh., 629
Hamilton, Dr. A. G.: Thelytokous Parthenogenesis for Four Generations in the Desert Locust (*Schistocerca gregaria* Forsk) (Acrididæ), 1153
Hamilton, H. A., and others: Friedrich Froebel and English Education (edited by Evelyn Lawrence), *review* by Miss P. M. Pickard, 219
Hamilton, Dr. Leonard: Utilization of Purines for Nucleic Acid Synthesis in Man, 457
Hamley, Dr. E. J.: Appointed a lecturer in physiology at the University of Birmingham, 1084
Hammond, Dr. John: Applications of 'Animal Physiology' to Agriculture, 437
    Preventive Medicine among Farm Livestock, 561
Hampshire: Pseudotuberculosis among Stock-Doves in (Dr. P. A. Clapham), 353
Hanaoka, Prof. Toshimasa: Effect of Melanophore Hormone on Regeneration of Visual Purple in Solution, 866
Hancock, J.: At the fourth meeting of the European Association of Exploration Geophysicists, 190
Hancox, Dr. N. M.: *Obituary* of Dr. C. E. Walker, 99
Hand, B. P.: High-Frequency Electrical Measurements, 53
Hannagan, M. J.: Appointed agricultural officer, Tanganyika, 1030
Hannan, Dr. R. S. Use of Fission Product Radiation, 148
Hannay, Dr. C. L. Crystalline Inclusions in Aerobic Spore-forming Bacteria, 1004
Hansch, Dr. C.: Chemical Structure in relation to Plant Growth-Regulating Activity, 710
Hanschell, M. A. G.: Appointed development commissioner, St. Lucia, 753
Hansel, C. E. M., and others: A New Phenomenon in Time Judgment, 901
Hanson, Prof. D.: *Obituary* by Dr. J. L. Haughton, 56
Hanson, Dr. Jean, and Huxley, Dr. Hugh E.: Structural Basis of the Cross-Striations in Muscle, 530
Haploid?: Are *Torulae* (Dr. M. K. Subramaniam and B. Ranganathan), 628
Haploid Number of Chromosomes in Mesenchymal Cells of the Tail Tip of *Rana pipiens* Tadpoles: Regular Occurrence of the (Dr. Elizabeth Ufford Green), 766
Happey, Dr. F., and others Structure of Wool, 673
Harding, Prof. D. W.: Psychological Problems in the Recognition of Excellence, 435
Hardisty, D. R. Awarded a postgraduate research scholarship by Courtaulds' Scientific and Educational Trust Fund, 383
Hardy, Dr. D. R., and others A Sealed-off Cathode-Ray Tube with Very High Writing Speed, 1056
Hardy, Dr. Margaret H., and others: Vaginal Cornification of the Mouse produced by Œstrogens *in vitro*, 1196
Harkins, Prof. William D.: The Physical Chemistry of Surface Films, *review* by Dr. James Bell, 828
Harkness, C.: Appointed plant breeder (botanist), Nigeria, 1085
Harland, Prof. S. C.: The Genetics of Garden Plants, *review*, 7
Harley, R. M.: Appointed a conservator of forests, Gold Coast, 234
Harmonics in the Spectrum of a Solar Radio Outburst Evidence of (J. P. Wild, J. D. Murray and W. C. Rowe), 533
Harmonics, Sidebands and Transients in Communication Engineering (C. Louis Cuccia), *review* by F. Horner, 5
Harper, P. J.: Appointed deputy director of agriculture, Sarawak, 234
Harries, W. L.: Electrical Insulation, 10
    Ionization Phenomena in Gases, 798
Harris, E. R. Elected president of the South-Western Naturalist's Union, 151
Harris, Frank E., and Alder, Berni J.: Restricted Rotation in Polar Gases near the Critical Point, 774
Harris, G. P.: Amino-Acids and the Growth of Isolated Oat Embryos, 1003
Harris, G. W.: Advances in Methods of Studying Clays, 288, 1085
Harris, Prof. G. W., and Pickles, Dr. V. R. Reflex Stimulation of the Neurohypophysis (Posterior Pituitary Gland) and the Nature of Posterior Pituitary Hormone(s), 1049
Harris, J. Maddern: Heartwood Formation in *Pinus radiata* (D. Don), 552
Harris, J. R. Influence of Rhizosphere Micro-organisms on the Virulence of *Rhizobium trifolii*, 507
Harris, Dr. Leslie J.: Scurvy in Retrospect, 50
Harris, Dr. Margaret M. (Turner, Prof. E. E., and): Organic Chemistry, *review* by Dr. J. D. Loudon, 135
Harrison, F. B., and others: Determination of Total Body Radioactivity using Liquid Scintillation Detectors, 521
Harrison, K.: Activation of Fumaric Hydrogenase by Ferrous Ions, 509
Harrison, Prof. R. G., and others: Aspects of Vitamin A Deficiency in Rats, 716
Hartland-Rowe, R.: Feeding Mechanism of an Ephemeropteran Nymph, 1109
Hartley, Dr. G. S.: Anticholinesterases, 841
    Organo-Phosphorus Insecticides, 944
Hartley, Sir Harold: The Life and Times of Sir Richard Gregory, 1864–1952, 526
    Needs of the Chemical Engineering Industry, 711
Hartog, H. den: Ionization Phenomena in Gases, 799
Hartshorn, Dr. L.: Electrical Insulating Materials, 8

Harun bin Taib, Che Mohd : Appointed assistant conservator of forests, Federation of Malaya, 1030
Harvey, Prof. A. W. : Empirical Research in Industry, 897
Harvey, C. O. : Rocks for Chemists, *review*, 137
Harvey, Dr. D. G. : Health, Welfare and Efficiency of the Worker, 1132
Harvey, L. A., and Leger-Gordon, D. St. : Dartmoor, *review*, 928
Harwell Isotope School : Courses on the Techniques of Using and Handling Radioactive Materials, 656, 1084
Hashimoto, Dr. Yohei, and Mori, Itsohiko : High-frequency Papyrography of Salts, 542
Haslett, A. W. (edited by) : Science News, 25, *review* by W. L. Sumner, 223
Hassel, Prof. O., and others : Nomenclature of *cyclo*Hexane Bonds, 1096
Hassion, F. X., and Cole, Prof. R. H. : Dielectric Relaxation Processes in Ethanol, 212
Hatching the Contents of Cysts of *Heterodera rostochiensis* with Alternating Temperature Conditions (Daphne D. Bishop), 1108
Haughton, Dr. J. L. : *Obituary* of Prof. D. Hanson, 56
Hauman, Prof. L. : Sur la Nécessité de distinguer une Région Afro-alpine pour la Végétation Africaine, 988
Havilland, Sir Geoffrey de : Elected an honorary fellow of the Royal Aeronautical Society, 571
Hawkins, G. S., and others : Radio Echo Observations of the Daytime Meteor Streams in 1952, 751
Hawkins, T. H. : Through Movement to Life, *review*, 7
  The Workers' Educational Association, *review*, 469
  Elementary Animal Ecology, *review*, 973
  Institute of Personnel Management, 1086
Hawksley, P. G. W. : Fine Particles and Statistics, *review*, 1017
Hawthorne, J. N. : Biochemical Problems of Lipids, 573
Hay, J. G., and Pridham, J. B. : Free Xylose in Fruits, 207
Hayek, Prof. F. A. : The Counter-Revolution of Science, Studies on the Abuse of Reason, 367
Hayes, F. N., and others : Determination of Total Body Radioactivity using Liquid Scintillation Detectors, 521
Hayes, J. E. : Technical Arrangements for the Sound and Television Broadcasts of the Coronation Ceremonies on 2nd June, 1953, 1129
Hayes, R. A. (Fantl, Dr. P., and) : Formation of Thromboplastin in Shed Mammalian Blood, 303
Hayes, R. C. : Earthquakes in New Zealand during 1951, 233
Hayes, W. D. : Wave Riding of Dolphins, 1060
Hays, Dr. Edwin E., and others : Awarded the Commercial Solvents Award in Antibiotics, 382
Haywood, C. A., and Moon, Prof. H. P. : Reversal of the Heart-beat in Tunicates, 40
Hazard, C. (Brown, R. Hanbury, and) : Radio-Frequency Radiation from the Spiral Nebula Messier 81, 853
  An Extended Radio-frequency Source of Extra-galactic Origin, 997
Hazelwood, A. : Museums and the Public, 107
Head, A. J. : Awarded a postgraduate research scholarship by Courtaulds' Scientific and Educational Trust Fund, 383
Head, A. K. : Plastic Deformation of Metals, 572
Heal, Dr. H. G. : A Microgasometric Procedure, 30
  Appointed lecturer in chemistry at Queen's University, Belfast, 1173
Health : Ministry of : Statutory Instruments 1172 and 1174, Use of Aureomycin and Penicillin, 382
Health and Agriculture in China (James Cameron Scott), *review* by Dr. Joseph Needham, 826
Health Education Journal : Special issue devoted to the subject of Group Discussion, 799
Health, Welfare and Efficiency of the Worker (British Occupational Hygiene Society Conference on), 568, 709, 1132
Healy, T. V., and Wand, Dr. G. M. : Solutions of Electrolytes in Organic Solvents, 149
Heap, H. R. : Electrical Insulation, 11
Hearing Research Unit : The R.A.F. Mobile (Air Vice-Marshal E. D. D. Dickson and L. J. Wheeler), 748
Heart Muscle : Porphyrin A and other Porphyrins from (Dr. R. Lemberg), 619
Heart Muscle Fibres : Enzymes of the Intercalated Disks of (Dr. Geoffrey H. Bourne), 588
Heart-beat in Tunicates : Reversal of the (C. A. Haywood and Prof. H. P. Moon), 40 ; (Dr. R. H. Millar), 41
Heartwood Formation in *Pinus radiata* (D. Don), (J. Maddern Harris), 552
Heat (A University Text-Book of Physics, Vol. 3), being the eleventh edition and a largely rewritten version of Poynting and Thomson's 'Text-Book of Physics', Vol. 3 (J. H. Awbery), *review* by H. L., 1069
Heat in Physical Systems : Heat Transfer Phenomena, the Flow of (Dr. R. C. L. Bosworth), *review*, 375
Heat Transfer from Water to Ice by Thermal Convection (J. M. Dumoré, H. J. Merk and Prof. J. A. Prins), 460
Heat Transfer Phenomena, the Flow of Heat in Physical Systems (Dr. R. C. L. Bosworth), *review*, 375
Heath, Dr. D. F. : Organo-Phosphorus Insecticides, 945
Heath, Dr. D. F., and Park, P. O. : An Irreversible Choline-esterase Inhibitor in White Clover, 206
Heath, G. A., and others : Microwave Spectrum of Penta-1·3-diyne, 771
Heating Instrument for the Accurate Determination of Mesomorphic and Polymorphic Transition Temperatures (Dr. G. W. Gray), 1137
Hedberg, Dr. O. : Some Taxonomic Problems concerning the Afro-alpine Flora, 988
Hedberg, R. W. : High-Frequency Electrical Measurements, 53
Hedger, K. S. : Appointed veterinary officer, Kenya, 1085
Hedgerow and Park Timber and Woods under Five Acres, 1951 (Forestry Commission, Census Report No. 2), 616
Heer, E. : Structure of the Atomic Nucleus, 486
Height in the Lower Atmosphere : Variation of Humidity with, 193
Heimburger, C. C. : Elected a Fellow of the Royal Society of Canada, 1176
Heisch, Dr. R. B., and Garnham, Prof. P. C. C. : Fortuitous Xeno-diagnosis of Bat Trypanosomiasis, 248
Helical Structure of Crystalline Deoxypentose Nucleic Acid (Dr. M. H. F. Wilkins, Dr. W. E. Seeds, Dr. A. R. Stokes and Dr. H. R. Wilson), 759
Helium in Meteorites and their Ages : Cosmic-Ray Production of (Dr. J. C. Dalton, Prof. F. A. Paneth, Dr. P. Reasbeck, Dr. S. J. Thomson and Dr. K. I. Mayne), 1168
Helium-3 in Meteorites : Production by Cosmic Rays of (Prof. F. A. Paneth, Dr. P. Reasbeck and Dr. K. I. Mayne), 200
Helium-4 : Classical Considerations on the Abnormal Properties of (S. F. B. Tyabji), 849
Helium Liquefier : A New Type of (H. M. Long and Prof. F. E. Simon), 581
Helix (2-Chain) : Evidence for, in Crystalline Structure of Sodium Deoxyribonucleate (Rosalind E. Franklin and R. G. Gosling), 156
Helix (Intra-) S—S Linked Structures for Insulin (Dr. U. W. Arndt and Dr. D. P. Riley), 245
Hellens, R. : Medium-Energy Nuclear Physics, 527
Heller, H. S. : Pharmacology of Renal Tubular Mechanisms, 1075
Helminthosporium oryzae Breda de Haan : Occurrence in Nature of an Alternative Host (*Leersia hexandra* Sw.) of (Dr. S. B. Chattopadhyay and N. K. Chakraborti), 550
Hemingway, Prof. A. : Physiology of Athletic Training, 934
Hemingway, R. G. : Appointed lecturer in agricultural chemistry at the University of Glasgow, 1030
Hemming, Francis : Zoological Nomenclature—Amendments to the International Code of Zoological Nomenclature, 830, 966, 1010
Hemming, H. G., and others : Humicolin, a New Antibiotic, 187
Hemming, H. G. (Jefferys, E. G., and) : Fungistasis in Soils, 872
Hempelmann, L. H., and others : Urinary Excretion of Acid and Neutral Deoxyribonuclease by Rats under Normal and Post-Irradiation Conditions, 867
Hen : Premature Oviposition in the (A. H. Sykes), 1098
Henbeart, Martha (Aarons, Jules, and) . Low-Frequency Noise in the Range 0·5–20 cycles per sec., 682
Henrici, Dr. Marguerite : Human Values in the Technical World, 476
Heparin-like Substance from Mast Cell Granules in Mouse Connective Tissue : Extraction of a (Dr. M. Koksal), 733
Hepatic Necrosis and Fibrosis : Experimental Production of, with Water (Prof. Wm. O. Reinhardt), 915
Hepper, B. T. : Artificial Infection of various Molluscs with *Mytilicola intestinalis*, Steuer, 250
Herbage (Grassland) : Purines in (W. S. Ferguson and R. A. Terry), 346
Herbert, W. J. : Appointed veterinary officer, Nigeria, 60
Herdan, Dr. G. : Estimation of Heterogeneity from Diffusion Measurements, 581
  Small Particle Statistics, *review* by P. G. W. Hawksley, 1017
Herdman, Dr. H. F. P. . The Deep Scattering Layer in the Sea—Association with Density Layering, 275
Heron, Dr. Alastair, and Venables, Dr. P. H. : Empirical Research in Industry, 898
Herrinck, P. : Gravity Survey in the Congo, 258
Herring (Spring and Autumn Spawning) : Sperm Storage and Cross-Fertilization of (J. H. S. Blaxter), 1189
Hervey, Dr. G. R., and McCance, Prof. R. A. : Provisioning of Expeditions in the Field, 974
Hesketh, R. V. : Recent Developments in Ultrasonics and Optics, 443
Heslop-Harrison, Dr. G. : Awarded a Leverhulme Research Grant for 1953, 17
Hess, Dr. W. R. . Honorary doctorate in science of McGill University conferred on, 1074
Heston, Dr. W. E. : Linkage between Pulmonary Tumours and Vestigial Tail in the House Mouse, 1007
Hestrin, Dr. Shlomo, and Goldblum, J. : Levanpolyase, 1046
Hestrin, Dr. Shlomo, and others : Promotion of Infection by Intravenously Administered Polysaccharides, 765
Heterocycles : Polycyclic Nitrogen, *review* by Prof. J. W. Cook, 882
Heterocyclic Compounds (edited by Robert C. Elderfield), Vols. 3 and 4, *review* by Prof. J. W. Cook, 882
Heterodera rostochiensis : Hatching the Contents of Cysts of, with Alternating Temperature Conditions (Daphne D. Bishop), 1108
Heterodera rostochiensis Wollenweber : Giant Larvae of the Potato Root Eelworm (T. G. Onions), 249
Heterogeneity of Deoxyribonucleic Acids (Dr. Geoffrey L. Brown and M. Watson), 339
Heterogeneity from Diffusion Measurements . Estimation of (Dr. G. Herdan), 581
Heteropycnosis in the Autosome Segments of *Ceriagrion coromandelianum* (Odonata) (Dr. M. D. L. Srivastava and C. C. Das), 765
Heterosis in Saccharomyces (Prof. Carl C. Lindegren, J. Edgar Braham and Juan de Dios Calle), 800
Heterothallism in *Chaetomium* (Ronald A. Fox), 165
Hetherington, G. : Elected a Salters' Scholar for 1953–54 by the Salters' Institute of Industrial Chemistry, 59
Hetherington, Sir Hector : The Social Function of the University, 132
  Finance of American Higher Education, *review*, 470
Heubner, Prof. W. O. L. . The Free University of Berlin, 942
Hewitt, Dr. L. F. : Adaptation in Micro-organisms, 236
Hexamita meleagridis (D. Slavin and J. E. Wilson), 1179
Hexavalent Chromium in an Atomic Pile : Szilard and Chalmers Effect by Irradiation of (Dr. B. Ottar), 362
Heymans, C. : Reflexes from the Cardiac and Pulmonary Areas, 1073
Heyn, Prof. A. N. J. . Small-Angle X-Ray Scattering and Interparticle Interference in Rayons, 1000
Heywood, A. (Cropper, F. R., and) : Analytical Separation of the Methyl Esters of the C_{12}–C_{22} Fatty Acids by Vapour-Phase Chromatography, 1101
Heywood, Dr. R. B. : Designing by Elasticity, *review* by E. K. Frankl, 926
Heywood, W. L. : Appointed a member of the Advisory Council for Scientific and Industrial Research, 571
Hiatt, Prof. Robert W., and others . Relation of Chemical Structure to Irritant Responses in Marine Fish, 904
Hibbert Lecture (Lord Samuel), 1171
Hick, Dr. W. E. : Cybernetics, 648
Hickin, Dr. N. E. . An Aquatic Larva, suitable for Laboratory Work, 874
Hickling, Dr. C. F. : Visitors' Tables at Colonial Fisheries Research Stations, 885
Hickman, Dr. C. J. : Genetical Aspects of Plant Disease, 989
Hickman, Dr. C. J., and Goode, Pamela M. : A New Method for testing the Pathogenicity of *Phytophthora fragariae*, 211
Higgins, H. G. (Fraser, Miss Dallas, and) : Spectrophotometric Determination of Amino-Groups, 459
Higgs, P. W. : Awarded a Senior Studentship for 1953 by the Royal Commission for the Exhibition of 1851, 17
High-Altitude Research Laboratory in Alaska, 143

High Contrast in the Photography of Interference Fringes : Use of (J. M. Hough and B. J. Goldsmith), 1105
High-Energy Electrons : Irradiation of Polymers by (E. J. Lawton, A. M. Bueche and J. S. Balwit), 76
High-Energy Particles (Prof. Bruno Rossi), *review* by Prof. J. C. Gunn, 472
High-Energy Physics, *review* by Prof. J. C. Gunn, 472
High-Frequency Electrical Measurements (American Institute of Electrical Engineers, the Institute of Radio Engineers and the National Bureau of Standards Conference on), 52
High-frequency Papyrography of Salts (Dr. Yobei Hashimoto and Itsuhiko Mori), 542
High Polymer Forum : Fifth Canadian, 708
High Pressures : The Melting of Iron at (Prof. F. E. Simon), 746
High-Resolution Autoradiographs : Automatic Grain Counter for Assessing Quantitatively (Dr. R. A. Dudley and Dr. S. R. Pelc), 992
High Speed : Aerodynamics of, Facsimiles of Nineteen Fundamental Studies as they were Originally Reported in the Scientific Journals (with a Bibliography compiled by Prof. George F. Carrier), *review*, 600
High-Speed Aerodynamics (W. F. Hilton), *review*, 600
High-Speed Aerodynamics (Prof. Harold W. Sibert), *review*, 600
High-Speed Rotation : Some Scientific Applications of (Prof. P. B. Moon), 22
High Temperature : Acceleration of Flowering in partially Vernalized Grain of Petkus Winter Rye by subsequent Treatment at (D. J. C. Friend and Prof. F. G. Gregory), 667
Higher Education for Africans in Central Africa, Commission on : Report of the, 1
Higher Personnel : Recruitment of, for the British Textile Industry, 707
Hildebrand, Prof. Joel H. (Latimer, Prof. Wendell M., and) : Reference Book of Inorganic Chemistry, third edition, *review* by Dr. D. S. Payne, 1068
Hilditch, Prof. T. P. : Production and Uses of Glycerine, *review*, 1066
Hill, Dr. R., and others : Production of Oxygen from Chloroplast Preparations—Active Chloroplast Preparations from *Chlorella pyrenoidosa*, 948
Hill, Sir Roderic : Elected vice-chancellor of the University of London, 18
  Higher Technological Education, 270
Hill, Dr. Rodney : Appointed to the chair of applied mathematics in the University of Nottingham, 103, 141 ; work of, 141
Hill, Dr. W. C. Osman : Primates, Comparative Anatomy and Taxonomy, 1, Strepsirhini, *review* by Prof. S. Zuckerman, 880
Hill Ewes : Milk Yield of (J. B. Owen), 636
Hilton, W. F. : High-Speed Aerodynamics, *review*, 600
Himmelweit, Dr. Hildegard T. : Title of reader in psychology in the University of London conferred on, 1085
Hindle, Dr. Edward : Science and Freedom, 445
Hinshelwood, Sir Cyril : Adaptation in Micro-organisms, 235
  Honorary degree of D.Sc. of the University of Sheffield to be conferred on, 1085
Hinson, W. H. (Dobbs, Dr. C. G., and) : A Widespread Fungistasis in Soils, 197
Hinton, Dr. J. J. C., and others : The B-Vitamins in Wheat—the Unique Aleurone Layer, 993
Hirsch, Dr. A. : Antibiotics, their Production and Use in Industry, 329
Hirst, Prof. E. L. : Chemistry of Starch, *review*, 972
Histochemistry and Cytochemistry, Journal of (American Histochemical Society), 232
Histochemistry of Xanthine Oxidase (Dr. Geoffrey H. Bourne), 193
Histological Brain Sections : A Selective Method for the Staining of Negri Bodies in (Dr. I. Zlotnik), 962
Histology (Prof. Arthur Worth Ham), second edition, *review* by Dr. G. H. Bourne, 1019
Histology in Transition, *review* by Dr. G. H. Bourne, 1019
Historical Aspects of Organic Evolution (Dr. Philip G. Fothergill), *review*, 375
History of Regional Farming in Britain, 985
History of Science A.D. 400–1650 : Augustine to Galileo, the (A. C. Crombie), *review* by Dr. W. P. D. Wightman, 134
Hitchcock, L. F. (Roulston, W. J., and) : Depletion of Gamma Isomer of Benzene Hexachloride in Cattle Dipping-Fluids, 546
Hives, Lord : Elected an honorary fellow of the Royal Aeronautical Society, 571
Hobbiger, Dr. F. : Anticholinesterases, 842
Hobhouse Memorial Lectures, 1941–50, *review*, 49
Hochstrasser, R. M. : Awarded a postgraduate research scholarship by Courtaulds' Scientific and Educational Trust Fund, 383
Hocking, C. : Biochemical Problems of Lipids, 573
Hodges, R. : Awarded an Overseas Scholarship for 1953 by the Royal Commission for the Exhibition of 1851, 17
Hodgson, H. C. : Appointed pyrethrum chemist, Kenya, 234
Hoeg, Dr. Ove Arbo : Birbal Sahni Institute of Palaeobotany, 104
Hoerlin, H., and others : Impurity Phenomena, 386
Hofstadter, R. : Structure of the Atomic Nucleus, 486
Holderness : Young Morainic Topography in (Dr. Hartmut Valentin), 919
Holdridge, D. A. : Advances in Methods of Studying Clays, 288
Holland, D. J. : Weather Inference for Beginners, *review*, 1069
Holleman, Prof. A. F. : *Death* of, 610 ; *obituary* by Dr. S. Coffey, 706
Hollett, Charlotte : At the XIX International Physiological Congress, Montreal, 1073
Hollingsworth, Miss D. F. : Provisioning of Expeditions in the Field, 974
Holman, Prof. R. T., and others (edited by) : Progress in the Chemistry of Fats and other Lipids, Vol. 1, *review* by Dr. J. A. Lovern, 740
Holmberg, Arne (edited by) : Bibliografi över J. J. Berzelius, Second Supplement, Parts 1 and 2, 1131
Holmes-Walker, W. A. : Elected a Salters' Fellow for 1953–54 by the Salters' Institute of Industrial Chemistry, 59
Holroyd, Dr. R. : Coal as a Source of Chemical Raw Material (Coal Science Lecture of the British Coal Utilisation Research Association), 613
Holton, Dr. P. M. (*née* Watson-Williams) : Appointed by the Royal Society to a Foulerton Research Fellowship at the Physiological Laboratory, University of Cambridge, 185
Home Civil Service Fellowships (Commonwealth Fund of New York), 612
Homing Pigeons : Aeroplane Observations of (Donald Griffin), 192
Honeycombe, Dr. R. W. K. : Progress in Metal Physics, Vol. 3, *review*, 94
Hopf, Dr. P. P. : Organo-Phosphorus Insecticides, 945
Hopkins, J. W. (Grace, N. H., and) : The Royal Society of Canada, Section V (Biological Sciences), 1175
Hopkins, Prof. R. H., and Bird, Dr. R. : The Z-Enzyme in Amylolysis, 492
Hopkinson, J. G. : Elected honorary secretary of the Society of Dyers and Colourists, 187
Hora, Dr. S. Lal : Conditions in the Rajputana Desert, 58
Horizontal Ampulla of the Isolated Elasmobranch Labyrinth : Effect of Galvanic Polarization on the Impulse Discharge from the (Prof. Otto Lowenstein), 549
Hormone (Adrenocorticotropic) : Influence of Hypophysectomy and of, on a Mammalian Adaptive Enzyme System (Dr. Irving I. Geschwind and Prof. Choh Hao Li), 732
  Non-Identity of Intermedin and (Prof. A. O. M. Stoppani, P. F. Pieroni and A. Murray), 547
Hormone (Melanophore) : Effect of, on Regeneration of Visual Purple in Solution (Prof. Toshimasa Hanaoka), 866
Hormone (Thyroid-stimulating), Thyroid and Thyroid-like Substances on *Xenopus* Tadpoles : Assay of (J. M. Dodd and Prof. F. W. Landgrebe), 121
Hormone(s) (Posterior Pituitary) : Reflex Stimulation of the Neurohypophysis (Posterior Pituitary Gland) and the Nature of (Prof. G. W. Harris and Dr. V. R. Pickles), 1049
Hormone-Fungicide Sprays for Control of *Botrytis* Fruit-Rot in Glasshouse Tomatoes : Combined (F. J. Newhook and R. M. Davison), 351
Hormones (Sex), and Cancer, *review* by Prof. W. S. Bullough, 1066
Hornby, H. J. : *Death* of, 938
Horner, F. : Modulation Theory in Radio Communication, *review*, 5
Horning, Eric S. (Burrows, Harold, and) : Œstrogens and Neoplasia, *review* by Prof. W. S. Bullough, 1066
Horsfall, W. R., and Lehmann, Dr. H. : Absence of the Sickle Cell Trait in Seventy-two Australian Aboriginals, 638
Horticulture : Applications of Electricity in, *review* by E. W. Golding, 1164
Horwood, M. T. : Appointed a senior assistant conservator of forests, Gold Coast, 234
Hosler, Dr. C. L. : Cloud Physics and Induced Precipitation, 1168
Hospers, J. : Magnetic Properties of the Earth's Interior, 787
Hospital Physicists' Association : Third Douglas Lea Memorial Lecture (Dr. A. Gluckman), 442
Host (*Leersia hexandra* Sw.) : Occurrence in Nature of an Alternative, of *Helminthosporium oryzae* Breda de Haan (Dr. S. B. Chattopadhyay and N. K. Chakraborti), 550
Host-Protein Component of Influenza Viruses (Prof. Wilson Smith, G. Belyavin and F. W. Sheffield), 669
Hosten, P. O. M. : Appointed agricultural officer (land settlement), Trinidad, 234
Hothersall Memorial Lecture for 1953–54 of the Institute of Metal Finishing (Dr. William Blum), 754
Houde, Mayor Camillien : Address at the XIX International Physiological Congress, Montreal, 1071
Hough, J. M., and Goldsmith, B. J. : Use of High Contrast in the Photography of Interference Fringes, 1105
Houghton, E. W. : High-Frequency Electrical Measurements, 53
Houghton, Prof. H. G. : Cloud Physics and Induced Precipitation, 1168
House Mouse : Linkage between Pulmonary Tumours and Vestigial Tail in the (Dr. W. E. Heston), 1007
  'Rabbit-Gait' in the (S. A. Mallyon), 312
Houseflies (Multi-Resistant) : Control of (H. Wichmand), 758
Houseflies (Resistant) : Amount of Gamma-Benzene Hexachloride picked up by, bred on a Medium containing Benzene Hexachloride (F. R. Bradbury, P. Nield and J. F. Newman), 1052
Houssay, Dr. B. A. : Metabolic Influence of Insulin, 1073
Howard, Dr. H. W. : Genetical Aspects of Plant Disease, 990
Howard, J. P. : Elected a Salters' Scholar for 1953–54 by the Salters' Institute of Industrial Chemistry, 59
Hoyaux, M. : Ionization Phenomena in Gases, 798
Hoyle, F. : Cosmic Origin of Radiation at Radio Frequencies, 296
Hoyle, G. : 'Slow' and 'Fast' Nerve Fibres in Locusts, 165
Hubble, Dr. E. P. : *Death* of, 610 ; *obituary* by Prof. F. J. M. Stratton, 793
Hubbs, Prof. C. : The Pacific Grey Whale, 830
Huddleston, A. : Appointed deputy director, Geological Survey Department, Gold Coast, 60
Hudson, Dr. J. C. : The Delhi Pillar, 499
Hudson, J. P. : Factors affecting the Regeneration of Root-Cuttings, 411
Hudson, Dr. O. F. : *Obituary* by Dr. S. W. Smith, 982
Hudson, R. F. : Dyeing and Tanning, 1031
Hughes, H. : Magnetic Properties of the Earth's Interior, 787
Hughes, H. K. : Awarded a citation by the American Association of Physics Teachers, 339
Hughes, L. C., and Fowler, H. D. : Resistance to a Plant Disease associated with High Glucose Content of Leaf, 316
Hughes Medal of the Royal Society awarded to Sir Edward Bullard, 893, 1022
Hull, G. W. : Impurity Phenomena, 387
Hulme, Dr. A. C. : A New Hydroxy-acid in the Peel of Apple Fruits, 346
Human Anæmias : Detection of Foetal and Sickle-cell Hæmoglobins in (Dr. G. H. Beaven and Dr. J. C. White), 1006
Human Blood-Group Gene intermediate between *M* and *N* (L. Dunsford, Elizabeth W. Ikin and Dr. A. E. Mourant), 688
Human Body : Measurement of the γ-Radiation from the (Dr. P. R. J. Burch and Prof. F. W. Spiers), 519
Human Ecology, *review* by Prof. L. Dudley Stamp, 422
Human Electroencephalogram : The Lambda Wave as a Normal Physiological Phenomenon in the (Dr. Martin Roth and Joy Green), 864
Human Factors in Nationalization : Economics and, 43
Human Foetus 28 Weeks Old : Formation of Neurofibrils in the Brain of a (M. C. H. Dodgson), 404
Human Mandible from a Levalloiso-Mousterian Horizon in Cyrenaica : A Fossil (Dr. C. B. M. McBurney, Dr. J. C. Trevor and Dr. L. H. Wells), 889
Human Physiology : Introduction to, *review* by Sir Charles Lovatt Evans, 4
Human Red Cells : Rates of Glycolysis in, in relation to Energy Requirements for Cation Transport (Ralph E. Bernstein), 911
Human Skeleton : Fluorine in the (Prof. John Read), 1156
Human Spermatozoa : Fertilizing Capacity of Frozen (Dr. R. G. Bunge and J. K. Sherman), 767
Human Urine : Tryptophane Metabolites in (Dr. M. Spaček), 204

Human Uterine and Vaginal Receptors during the Menstrual Cycle: Variations in the Content of Deoxyribonucleic Acid in the (R. Vokaer, Cl. Gompel and A. Ghilain), 31
Human Values: Science and the Discovery of (Prof. Arthur H. Compton), 476
Human Values in the Technical World (Public Lectures at the Eleventh Conference of the International Federation of University Women), 475
Human Visual Purple (Dr. F. Crescitelli and Dr. H. J. A. Dartnall), 195
Humanist: The Geographer as (Prof. R. H. Kinvig), 432
Hume-Rothery, Dr. W.: Progress in Metal Physics, *review*, 223
Humicolin, a New Antibiotic (P. J. Curtis, H. G. Hemming and E. G. Jeffreys), 187
Humidity: Variation of, with Height in the Lower Atmosphere, 193
Humidity Gradients in the First 100 m. over South-East England: Temperature and (A. C. Best, E. Knighting, R. H. Pedlow and K. Stormonth), 193
Humphrey, L.: Appointed senior meteorological officer, Gold Coast, 1030
Humphreys, O. W.: Appointed to the board of directors of the General Electric Co., Ltd., 101; work of, 101
Humphrys, A. R.: Appointed agricultural officer, Uganda, 1030
Hunger: Impulses in Vagal Afferent Fibres from Stretch Receptors in the Stomach and their Role in the Peripheral Mechanism of (Dr. A. S. Paintal), 1194
Hungry People: Unused Land and, *review* by Sir John Russell, 266
Hunt, Dr. N. C.: Supply and Education of Managers for British Industry, 714
Hunt, S. E., and others: Half-value Periods for the Decay of Aluminium-26, Aluminium-25 and Nitrogen-13, 460
Hunter, Dr. Herbert: The Barley Crop, *review* by Sir John Russell, 600
Hunter, I. M. L.: Rat Behaviour, 488
Hunter, Sir Thomas: *Death of*, 15
Huntley, Prof. H. E.: Radio-Astronomy in the Tropics, 108
  Dimensional Analysis, *review* by Dr. C. A. Taylor, 741
Huot, G.: At the fourth meeting of the European Association of Exploration Geophysicists, 190
Hurcomb, Lord: Oil Pollution of the Sea, 1025
Hurst, Dr. R.: Transmutation of the Elements, 607
Hurwitz, H. B. M.: Rat Behaviour, 489
Huskins, Prof. C. Leonard: *Death of*, 439
Hutchings, D. A.: Appointed veterinary officer, Northern Rhodesia, 60
Hutchinson, Dr. S. A., and Walton, Prof. J.: A Presumed Ascomycete from the Upper Carboniferous, 36
Hutchinson, G. W.: Appointed lecturer in experimental physics at the University of Glasgow, 1030
Hutt, Prof. W. H.: Higher Technological Education, 271
Huus, T.: Structure of the Atomic Nucleus, 486
Huxley, Dr. Hugh E. (Hanson, Dr. Jean, and): Structural Basis of the Cross-Striations in Muscle, 530
Huxley, Dr. Julian: Awarded the Kalinga Prize for 1953, 60
Huxley, T.: Awarded a Nature Conservancy Research Studentship in Zoology, 708
Huxley: Wilberforce and, on Evolution (D. J. Foskett), 920
Hydration Structure of Deoxyribonucleic Acid and its Physico-Chemical Properties (Dr. Bertil Jacobson), 666
Hydrocarbon Combustion: Chemiluminescent Phenomena during (Prof. R. G. W. Norrish, Dr. G. Porter and B. A. Thrush), 71
Hydrocarbon Free Radicals: Reaction of Nitric Oxide with Gaseous (H. T. J. Chilton and Dr. B. G. Gowenlock), 73
Hydrocortisone: Radioactive Cortisone and, 187
Hydrodynamical Theory of Detonation and Shock Waves, *review* by Prof. D. M. Newitt, 699
Hydrogen, Chlorine and Nitrogen Trichloride: Explosions in Mixtures of (Dr. P. G. Ashmore), 449
Hydrogen Peroxide: Analysis of Organic Hydroperoxides in the presence of (H. Bruschweiler, G. J. Minkoff and K. C. Salooja), 909
  Effects of Commercial and Radiation-produced (Tikvah Alper), 957
Hydrogen Peroxide in Water: Formation of, by 1-MeV. Protons (Dr. R. J. Shalek and Prof. T. W. Bonner), 259
Hydrogen Sulphide (Radioactive): Quantitative Paper Chromatography of Traces of Metal with the Aid of (P. C. van Erkelens), 357
Hydrogenase (Fumaric): Activation of, by Ferrous Ions (K. Harrison), 509
Hydrographic Bureau, International: Limits of Oceans and Seas, third edition, 484
Hydrography in relation to Fisheries (Dr. John B. Tait), *review* by David Vaux, 179
Hydrolysate of Glutathione: Isolation of a Mixed Disulphide of Glutathione and Cysteinylglycine from a Partial (Dr. Eskil Wikberg), 398
Hydrolysis: Enzymatic, of Urinary Neutral 17-Ketosteroid Conjugates (S. R. Stitch and I. D. K. Halkerston), 398
Hydrolysis of Casein *in vitro*: Action of Duck's Egg White Ovomucoid on Tryptic (P. K. Vijayaraghavan and B. S. Narasinga Rao), 1152
Hydrolysis of Esters by Extracts of Insects (K. A. Lord and Dr. C. Potter), 679
Hydrolysis of Organic Nitrites (A. D. Allen), 301
Hydrolysis of Xylan: Enzymatic (Dr. Henning Sorensen), 305
Hydrolytic Enzymes: Transferase Activity of (Dr. R. K. Morton), 65
Hydroperoxides (Organic): Analysis of, in the presence of Hydrogen Peroxide (H. Bruschweiler, G. J. Minkoff and K. C. Salooja), 909
Hydrophilic Penicillins produced by *Penicillium chrysogenum* (Dr. C. W. Hale, G. A. Miller and B. K. Kelly), 545
Hydroquinone: Effect of, on Mitosis (Dr. A. Rosin and F. Doljanski), 1151
Hydrostatic Pressure: Variation of the Incompressibility of an Elastic Material subjected to Large (A. Keane), 117
Hydroxide Ions in Ethanol: Equilibrium between Ethoxide and (Dr. E. F. Caldin and G. Long), 583
Hydroxy-acid in the Peel of Apple Fruits: A New (Dr. A. C. Hulme), 346
Hydroxy-proline: 'Multiple Dipping' Procedures in Paper Chromatography—a Specific Test for (Dr. John B. Jepson and Ivor Smith), 1100
5-Hydroxytryptamine: Detection of, in Mammalian Enterochromaffin Cells (Dr. R. Barter and Dr. A. G. Everson Pearse), 810
  Detection of, by Paper Chromatography (Dr. D. M. Shepherd, Dr. G. B. West and Dr. V. Erspamer), 357
5-Hydroxytryptamine in a Carcinoid Tumour (Dr. F. Lembeck), 910
Hydroxytyramine in Extracts from Insects: Adrenaline, Noradrenaline and (Dr. Eric Östlund), 1042
Hygrine Bases: A Possible Common Biogenetic Origin of the Nicotine, Tropane and (P. I. Mortimer), 74
Hynam, C. A. S.: Appointed agricultural officer, British Honduras, 753
Hyperthyroid Rats: An Unidentified Growth-Factor for Yeast and (Dr. E. Tria and Dr. O. Barnabei), 203
Hypopachus aguae Stuart: Respiratory and Digestive Anatomy of a Microhylid Tadpole (R. Maxwell Savage), 354
Hypophysectomy: Changes in the Vascular and Lipoid Pattern of the Adrenal Cortex of the Rat following (J. D. Lever, Dr. D. B. Cater and M. P. Stack-Dunne), 33
  Influence of, and of Adrenocorticotropic Hormone on a Mammalian Adaptive Enzyme System (Dr. Irving I. Geschwind and Prof. Choh Hao Li), 732

ICE: Heat Transfer from Water to, by Thermal Convection (J. M. Dumoré, H. J. Merk and Prof. J. A. Prins), 460
Ice (Polycrystalline): Rate of Flow of (J. W. Glen), 721
Identification of Amino-Acids: Qualitative Organic Micro-analysis based on Physical Constants— (Dr. A. Lacourt, G. Sommereyns, C. Francotte and N. Delande), 906
Identification of Amino-Acids present in Purified Prothrombin by Circular Paper Chromatography (Gauranga Ray, N. C. Ganguli and S. C. Roy), 809
Identification of Flavones by the Ultra-Violet Absorption Spectra of their Ions (G. H. Mansfield, Dr. T. Swain and C. G. Nordström), 23
Igneous Rocks: Origin of Reverse Thermoremanent Magnetism of (Prof. T. Nagata, S. Akimoto and S. Uyeda), 630
  Self-Reversal of Thermoremanent Magnetization of (Prof. Takesi Nagata), 850
Ikin, Elizabeth W., and others: A Human Blood-Group Gene Intermediate between *M* and *N*, 688
Illinois: The Algae of (Lewis Hanford Tiffany and Max Edwin Britton), *review* by Prof. F. E. Fritsch, 268
Illness in Twins: Psychotic and Neurotic (Eliot Slater, with the assistance of James Shields), *review* by Dr. Clifford Allen, 739
Illuminating Engineering Society: Awards, 709
Illumination: Dark-Ground, of Ram Spermatozoa (H. M. Dott), 626
Illumination, International Commission on: Special Meeting of the Technical Committee on Daylight, 59
Immunologically Specific Adsorbent: Antibody Chromatography on an (L. S. Lerman), 635
Impact of Industry on the Worker (Nigel Balchin), 483
Imperfections in Metals, *review* by Dr. H. Lipson, 266
Imperfections in Nearly Perfect Crystals (Symposium held at Pocono Manor, October 12–14, 1950, sponsored by the Committee on Solids, Division of Physical Sciences, the National Research Council), *review* by Dr. H. Lipson, 266
Imperial Chemical Industries, Ltd.: Appointment of G. S. J. White as director of the Dyestuffs Division in charge of Technical Service Departments, 277
Imperial College of Science and Technology: Election of Sir Roderic Hill as vice-chancellor of the University of London, 18
  Title of professor emeritus of mathematics in the University of London conferred on Prof. W. G. Bickley, 234
  Title of professor emeritus of plant pathology in the University of London conferred on Prof. William Brown, 234
  Title of professor emeritus of zoology and applied entomology in the University of London conferred on Prof. J. W. Munro, 234
  Appointment of J. R. Ashby to the University of London readership in civil engineering, 234
  Appointment of Dr. C. C. Butler to the University of London readership in physics, 234
  Appointment of Dr. R. M. Goody to the University of London readership in meteorology, 234
  Vacation School on Analysers and Computers for Electrical Systems, 614
  Appointment of Dr. P. H. Gregory as head of the Botanical Department and University of London professor of plant pathology, 797, 838
  Retirement of Prof. W. Brown as head of the Botanical Department and University of London professor of plant pathology, 838
  Appointment of Dr. O. W. Richards to the University of London chair of zoology and applied entomology, 895, 1027
  Retirement of Prof. J. W. Munro from the chair of zoology and applied entomology, 1027
Implantation: Delayed, in the Elephant Seal (L. Gibbney), 590
Implements (Piltdown): Chemical Examination of the (Dr. K. P. Oakley and J. S. Weiner), 1110
Impulse Discharge from the Horizontal Ampulla of the Isolated Elasmobranch Labyrinth: Effect of Galvanic Polarization on the (Prof. Otto Lowenstein), 549
Impulses in Vagal Afferent Fibres from Stretch Receptors in the Stomach and their Role in the Peripheral Mechanism of Hunger (Dr. A. S. Paintal), 1194
Impurities: Influence of some, notably Potassium, upon the Reactivity of Iodine Pentoxide towards Carbon Monoxide (E. G. Adams and N. T. Simmons), 1104
Impurities from Methanolic Solution at −30° C.: Purification of Secretin by Freezing Out of (J. E. Jorpes and V. Mutt), 124
Impurity Phenomena (Division of Physical and Inorganic Chemistry and the Eastern New York Section of the American Chemical Society in conjunction with the Division of Solid State Physics of the American Physical Society Symposium on), 385
'Incomplete' Virus Production: Absence of, in certain Influenza Strains (Dr. S. Fazekas de St. Groth and Miss Doris M. Graham), 1193
Incompressibility of an Elastic Material subjected to Large Hydrostatic Pressure: Variation of the (A. Keane), 117
Incorporation of Adenine into Adenosine Monophosphate: Mechanism of the (Murray Saffran and Eduardo Scarano), 949, A New Phosphokinase, 5-Phosphoribokinase (Eduardo Scarano), 951
Incretory Centres of *Locustana pardalina* during Embryogenesis: Activity of the—Function of the Prothoracic Glands (Dr. Bryn M. Jones), 551
Incubation: Glutamotransferase in the Chick Embryo during (D. Rudnick, P. Mela and Dr. H. Waelsch), 253

Index to Theses accepted for Higher Degrees in the Universities of Great Britain and Ireland (Aslib), Vol. 1, 985
Indexers (Specialist): Register of (Aslib), 143
India: Beautifying (M. S. Randhawa), *review*, 49
India (South): *Cryptolaemus montrouzieri* Mulsant in (W. Wilson Mayne), 85
India and Burma: Forest Research in, 1948–49, 233
Indian Epigraphy and South Indian Scripts (C. Sivaramamurti), *review* by M. C. Goswami, 374
Indian Meteorological Office: Kodaikanal Observatory 1901–51, 485
Indian National Scientific Documentation Centre: Report for 1952–53, 752
Indian Ocean: Seismic Refraction Experiments in the, and in the Mediterranean Sea (Dr. T. F. Gaskell and J. C. Swallow), 535
Indian Partridges: A Plasmodium in Common (A. P. Ray, V. N. Bhatnagar and M. K. Menon), 687
Indian (South) Scripts: Indian Epigraphy and (C. Sivaramamurti), *review* by M. C. Goswami, 374
Indies (West): First Record of the Rare Beaked Whale, *Mesoplodon europaeus*, Gervais, from the (J. J. Rankin), 873
Indirect Action of X-Radiation at various Concentrations on *E. coli*: Quantitative Aspects of the (C. Biagini), 868
Indolepyruvic Acid in Maize (Bruce B. Stowe and Prof. Kenneth V. Thimann), 764
Industrial Applications: Colloid Science and some of its (Dr. R. Matalon), 19
Industrial Directors and Managers: Report of the Third Conference of (Federation of British Industries), 757
Industrial Efficiency and Scientific Research, 877
Industrial Engineers, Society of: New title of the Institute of Economic Engineering, 18
Industrial Processes: Automatic Control of Mechanisms and, *review* by Prof. J. Greig, 91
Industrial Research in Great Britain: American Aid for Scientific and, 528
Industrial and Technological Research in Britain: American Aid for, 15
Industries: Nationalized, in Great Britain—Relations with the Public, 151
Industry: Antibiotics, their Production and Use in (Society of Applied Bacteriology Symposium on), 329
  Empirical Research in (Acton Society Trust and the York Civic Trust Discussion on), 897
  The Essential Oils, *review* by Dr. E. G. Kellett, 133
  Impact of, on the Worker (Nigel Balchin), 483
  Research in, 1029
  Use of Scientific and Technical Development by, 87
  The Utilization of Digital Computing Machines in Engineering and (British Association for the Advancement of Science, Section G (Engineering), Symposium on), 649
Industry (British): Supply and Education of Managers for, 714
Infection: Promotion of, by Intravenously Administered Polysaccharides (M. Shilo, D. Feingold and Shlomo Hestrin), 765
Infection of various Mollusca with *Mytilicola intestinalis*, Steuer: Artificial (B. T. Hepper), 250
Infections of *Trichostrongylus retortaeformis*: Phenomenon of Protection in (J. F. Michel), 312
Infectious Disease: Natural History of (Sir Macfarlane Burnet), second edition, *review* by Sir Philip Manson-Bahr, 927
Infectious Laryngotracheitis Virus: Possible *P–Q* Type Variation in (M. F. Pulsford), 1193
Infertility and Sterility: Prize for an Essay on (American Society for the Study of Sterility), 656
Inflation (Monetary): Open and Repressed (Prof. F. W. Paish), 433
Influence of Cysteamine, Methylamine and Cortisone on the Toxicity and Activity of Nitrogen Mustard (Dr. O. Peczenik), 454, *erratum*, 942
Influence of some Impurities, notably Potassium, upon the Reactivity of Iodine Pentoxide towards Carbon Monoxide (E. G. Adams and N. T. Simmons), 1104
Influence of Light on Germination: Factors modifying the (Prof. Michael Evenari, Dr. Gert Neumann and Dr. Gabriel Stein), 452
Influenza Strains: Absence of 'Incomplete' Virus Production in certain (Dr. S. Fazekas de St. Groth and Miss Doris M. Graham), 1193
Influenza Virus and Receptor-destroying Enzyme: Turbidity-reducing Activity of, on Sheep Submandibular Mucoid (Dr. J. F. McCrea), 912, 1173
Influenza Viruses: A Host-Protein Component of (Prof. Wilson Smith, G. Belyavin and F. W. Sheffield), 669
Information (Specialized): Directory of Sources of, in Great Britain and Ireland (Aslib), 613
Information Service (Aslib Residential Conference on), 18
Information Theory (Dr. P. M. Woodward), 58
Infra-Red Dichroism in Synthetic Polypeptides (Dr. A. Elliott), 359
Infra-Red Spectra (Report of the Joint Committee of the Royal Society, the Chemical Society, the Physical Society, the Faraday Society, the Institute of Petroleum, and the Society of Public Analysts and other Analytical Chemists on), 795
Infra-Red Spectra: Specificity of (L. D. P. Wootton), 954
Infra-Red Spectra of Proteins—the 6·5-μ Band: Contribution of Side-Chains to the (Dr. Gert Ehrlich and Prof. G. B. B. M. Sutherland), 671
Infra-Red Spectrometers employing Rotating Twin Cells: A Double-Beam System for (N. H. E. Ahlers and H. P. Freedman), 260
Ingold, Prof. C. K.: Honorary degree of D.Sc. of the University of Sheffield to be conferred on, 1085
Ingram, J. S.: The *Luffa* Plant and its Uses, 612
Inhibition of *Fusarium culmorum* by *Streptomyces albidoflavus* (F. A. Skinner), 1191
Inhibition of Superovulation in the Rabbit (C. E. Adams), 82
Inhibitor: An Irreversible Choline-esterase, in White Clover (D. F. Heath and P. O. Park), 206
Inhibitory Action of Cocaine (Brenda E. Ryman and Dr. E. O'F. Walsh), 679
Inhibitory Effects in Nodule Formation: Mutual (P. S. Nutman), 570
Initiation and Growth of Explosion: Size Effects in the (Dr. F. P. Bowden and K. Singh), 378
Injury: Cortisone and the Metabolic Response to (Rosa M. Campbell, Gillian Sharp, A. W. Boyne and Dr. D. P. Cuthbertson), 158
Innes (John) Horticultural Institution: Appointment of W. J. C. Lawrence as acting director, 613
Inorganic Sulphate: Influence of, on the Copper–Molybdenum Interrelationship in Sheep (A. T. Dick), 637
Insect: Secretion of an Orthodiphenol in the Corpus Cardiacum of the (M. L. Cameron), 349
Insect Cuticular Waxes: A New Method for Determining the Transition Temperature of (P. J. Judge), 405
Insect Tracheoles: Motility of (Prof. V. B. Wigglesworth), 247
Insecticide Manufacturers (British), Association of, and others: National Weed Control Conference, 442
Insecticides: Action of, on a Stem Borer of Oats—the Frit Fly (P. T. Walker), 916
  Organo-Phosphorus (Crop Protection Panel of the Society of Chemical Industry, the Association of Applied Biologists, the Biological Methods Group of the Society of Public Analysts and other Analytical Chemists, and the Pharmacological Society Symposium on), 944
  Specifications for (World Health Organization Expert Committee on Insecticides), 142
Insects: Adrenaline, Noradrenaline and Hydroxytyramine in Extracts from (Dr. Eric Östlund), 1042
  Hydrolysis of Esters by Extracts of (K. A. Lord and Dr. C. Potter), 679
  Occurrence and Endodermal Origin of the Peritrophic Membrane in some (D. F. Waterhouse), 676
Institut pour l'Encouragement de la Recherche Scientifique dans l'Industrie et l'Agriculture: Rapport Annuel, Exercice 1952, 387
Institut Français du Caoutchouc, and others: Revised System of Classification of Information on Rubber, 144
Institut International du Froid: Joint Meeting of the First and Second Commission to be held at Zurich, 18
Institut National pour l'Étude Agronomique du Congo Belge: Essences Forestières et Bois du Congo, Fasc. 1, Introduction (Jean Louis et Joseph Fouarge), 1177
Instrument Industries' Exhibition: British, 184
Insulation: Electrical (Institution of Electrical Engineers Symposium on), 8
Insulators: Effect of Temperature on the Conductivity Induced in, by X-Rays (N. W. Ramsey), 214
Insulin: Effect of, on the Adrenergic Amines of Blood (Dr. H. Weil-Malherbe), 396
  Intra-Helix S—S Linked Structures for (Dr. U. W. Arndt and Dr. D. P. Riley), 245
  Structure of (Dr. Conmar Robinson), 773
  Structure of, as indicated by Atomic Models (Dr. Conmar Robinson), 27
Insulin Molecule: Experimental Data and Model Structures for the (Dr. Barbara W. Low), 1146
Intellectual Freedom: The Defence of, 217
Interaction: Morphogenetic, between Embryonic Mouse Tissues separated by a Membrane Filter (Dr. Clifford Grobstein), 869
Interaction between Crystal Slip and Grain Boundary Movement (D. McLean), 300
Interaction of Science and Society, 1014
Interaction between Surfaces in Close Proximity (L. F. Evans), 776
Interactions (Antigen–Antibody): Detection of, by an Interferometric Method (E. J. Ambrose and G. C. Easty), 811
Interactions in Polyelectrolyte Solutions: Effects of Salts on (Prof. J. A. V. Butler and Dr. B. E. Conway), 153
Intercalated Disks of Heart Muscle Fibres: Enzymes of the (Dr. Geoffrey H. Bourne), 588
Interchange of Technical Publications, Sheffield Organization for the: Twentieth Annual Meeting, 382
Interconversion of Porphyrins in a Tissue System: Porphobilinogen as a Porphyrin Precursor, and (J. E. Falk, E. I. B. Dresel and C. Rimington), 292
Interfaces (Dielectric–Air): Thin Metallic Films for Anti-Reflexion Coatings on (F. H. Smith), 462
Interference Fringes: Use of High Contrast in the Photography of (J. M. Hough and B. J. Goldsmith), 1105
Interference Methods (Optical): A Comparison between the X-Ray Absorption and, for the Mass Determination of Biological Structures (Dr. H. G. Davies, Prof. A. Engstrom and Dr. B. Lindstrom), 1041
Interference and Diffraction of Light from Finite Sources: A Macroscopic Theory of (Dr. E. Wolf), 535
Interferometer for Simultaneous Observation of Concentration and Concentration Gradient in Liquid Columns (Dr. W. Weinstein), 461
Interferometric Method: Detection of Antigen–Antibody Interactions by an (E. J. Ambrose and G. C. Easty), 811
Intermedin: Chromatographic Behaviour of, as determined by *in vitro* Assays (Robert R. Kahn), 1185
Intermedin and Adrenocorticotrophic Hormone: Non-Identity of (Prof. A. O. M. Stoppani, P. F. Pieroni and A. Murray), 547
Internal Combustion Engine Research Association, British: Re-election of H. Norman G. Allen as chairman of Council, 280
International Affairs, Royal Institute of: Booklet on World Production of Raw Materials, new revised edition, 442
  Booklet on Springs of Canadian Power, 442
International Association of Gerontology: Third Congress, 1131
International Association of Limnology: Twelfth International Congress of Limnology, 888
  Election of Officers, 889
International Association on Quaternary Research: Appointment of a Committee on Pleistocene Correlation and Nomenclature, 942
International Botanical Congress to be held in Paris in 1954, 840
International Commission on Glass: Annual Meeting, 287
  Election of Dr. B. P. Dudding as president, 287
  Election of Prof. W. E. S. Turner as honorary president, 287
International Commission on Illumination: Special Meeting of the Technical Committee on Daylight, 59
International Committee of Acoustics: International Electro-Acoustics Congress, 189, *corrigendum*, 384
International Conference on Cosmic Radiation (University of Toulouse), 477
International Conference on Electron Microscopy, 334
International Conference on Ionization Phenomena in Gases (Physical Society, the Institute of Physics and the Electrical Research Association), 798

International Conference on Oil Pollution of the Sea, 1025
International Conference of Parapsychological Studies, 444
International Conference on the Science and Applications of Photography (Royal Photographic Society), 145, 1121
International Conference on Theoretical Physics—Meeting in Japan (Prof. N. F. Mott), 886
International Congress of Alpine Meteorology : Third, 840
International Congress of Botany . Eighth, 583
International Congress of Chronometry (Société Chronométrique de France), 942
International Congress on Crystallography (International Union of Crystallography), 613
International Congress of Electroencephalography and Clinical Neurophysiology Third, 145
International Congress of Genetics : Ninth (Dr. G. Pontecorvo), 756, 840
International Congress on Glass : Third, 287
International Congress of Limnology . Twelfth (Prof. F. E. Fritsch), 888
International Congress on Rheology . Second (Dr. G. W. Scott Blair), 487
International Congress of Science and Freedom, 445
International Congress of Zoology Fourteenth (Dr. L. Harrison Matthews), 829
International Control of Atomic Energy : Proposals for the (President Eisenhower), 1129
International Co operation in African Botany (J P M. Brenan), 987
International Co-operation in Science . Development of (A Symposium held in conjunction with the Third Annual Meeting of the Executive Board, International Council of Scientific Unions), 21
International Council for Electrodeposition : Conference in London, 754
International Council of Scientific Unions Development of International Co operation in Science, a Symposium held in conjunction with the Third Annual Meeting of the Executive Board, 21
    Formation of a Joint Commission on Electron Microscopy, 334
    Report of the Abstracting Board, 991
International Electro Acoustics Congress, 189, *corrigendum*, 384
International Federation of University Women : Eleventh Conference, 103, 475
    Election of Officers for 1953–56, 475
    Public Lectures on Human Values in the Technical World, 475
International Geophysical Year 1957–58 (Prof. Sydney Chapman), 327
International Hydrographic Bureau : Limits of Oceans and Seas, third edition, 484
International Institute of Refrigeration : Joint Meeting at Zurich of Commissions I and II, 708
International Laboratory for Nuclear Research (D. W. Fry), 646
International Physiological Congress, Montreal : XIX (Dr. W. L. M. Perry), 1071
International Phytogeographical Excursion . Tenth (Prof. P. W. Richards), 566
International Radio Consultative Committee : Forthcoming Plenary Assembly in London, 107
International School of Physics (Italian Physical Society), 146
International Scientific Abstracting, 991
International Scientific Film Association . Seventh Congress, 145
    Annual Congress in London (J. Stewart Cook), 1133
    Election of Officers for 1953–54, 1134
International Scientific Radio Union (Commission VI), and others : Symposium on Microwave Optics, 615
International Scientific Unions Activities of, 440
International Society for the Study of Biological Rhythms Fourth Conference, 943
International Union of Chemistry : Symposium on Geochemistry, 659
    Election of Prof. H. C Urey as a member of the Commission on Geochemical Localization of the Elements, 659
    Election of Officers of the Commission on Geochemical Localization of the Elements, 659
International Union of Crystallography : Third General Assembly and International Congress, 613
International Union of Pure and Applied Physics, and others : Conference on Optics and Microwaves, 102
International Union of Physiological Sciences : Formation of an, 1074
International Wool Secretariat World Wool Map, 18
Interparticle Interference in Rayons Small Angle X-Ray Scattering and (Prof A. N J Heyn), 1000
Interpretation of Nuclear Data, *review* by Dr. K. J Le Couteur, 785
Inter-relations between Filarial and Malarial Infections in *Anopheles gambiae* (Dr. R. C. Muirhead-Thomson), 352
Interrelationships of the Erythrocytes of various Species with Plant Agglutinins : Some (Lieut.-Colonel G. W. G. Bird), 401
Intersexuality in *Asellus aquaticus* L. parasitized by a Larval Acanthocephalan (W. R. Munro), 313
Interstitial Atoms in the Layer Structure $ZnMn_3O_7 3H_2O$ (Chalcophanite), (A. D Wadsley), 1103, *erratum*, 1173
Intertidal Animals Isolation of, by Sea Barriers (Dr. D. J. Crisp and Dr. A. J. Southward), 208
Intertidal Height Rate of Activity as a Function of, within Populations of some Littoral Molluscs (Earl Segal, K. Pampapathi Rao and Thomas W. James), 1108
Intestinal Amoebae Rapid Staining of, on Wet Mounts (C. P. Nair), 1051
Intestine (Small) Mucus-producing Goblet Cells of the (H Moe), 309
Intra-Helix S—S Linked Structures for Insulin (Dr. U. W. Arndt and Dr. D. P. Riley), 245
Intracellular Distribution of Rhodanese in Cardiac Muscle (Jennifer M. Moyle), 508
Intracellular Distribution of Vitamin A Esterase Activity in Rat Liver (Dr. J. Ganguly and Prof. H. J. Deuel, jun.), 120
Intranuclear Inclusions in Virus-diseased Cells of Lepidopterous Larvae : Development of (N Xeros), 309
Intranuclear Proteins of the Oocytes in *Artemia salina* L. (N. Fautrez-Firlefyn and Prof. J Fautrez), 163
Intravenously Administered Polysaccharides : Promotion of Infection by (M. Shilo, D. Feingold and Shlomo Hestrin), 765
Intrinsic Value of Science, 417
Invariant : An Extended Smith–Lagrange (Dr. G. L. Rogers), 118
Inventions and Designs (Crown Use) Bill, 1130
Iodine Pentoxide towards Carbon Monoxide : Influence of some Impurities, notably Potassium, upon the Reactivity of (E. G. Adams and N. T. Simmons), 1104
p-Iodophenylhydroxylamine (Radioactive) . Studies with Erythrocytes labelled with (Dr. Harold Jackson), 80
Ion : The 'Protactinyl' (G. A. Welch), 458
Ion Exchange Importance of, with the Solvent in Kinetic Studies (Dr. J W. Baker and A. J. Neale), 583
Ion-exchanged Forms of Chabazite : Structure of (I. R. Beattie), 999
Ionian Sea Earthquake Swarm in the (Ernest Tillotson), 332
Ionium : Angular Correlation of *a*-Particle and Conversion-Electron from the Decay of (Dr R. R. Roy and Miss M L. Goes), 360
Ionization produced by Positrons and Electrons : Specific (R. R. Roy and M Edenne), 953
Ionization of Nitrogen Molecules . Recombination Coefficient in the *F*-Regions—a Possible New Process of (R. B. Banerji), 953
Ionization Phenomena in Gases (Physical Society, the Institute of Physics and the Electrical Research Association International Conference on), 798
Ionosphere : Die (Dr. Karl Rawer), *review* by C. M. Minnis, 514
Ionosphere Investigation of Travelling Disturbances in the, by Continuous-Wave Radio (Y V. Somayajulu), 818 ; (B. Ramachandra Rao and E. Bhagiratha Rao), 819
    Physics of the, *review* by C. M. Minnis, 514
    Travelling Disturbances in the (R. E. Price), 155
Ionosphere observed in Great Britain during 1930–1946 . Characteristics of the (Department of Scientific and Industrial Research, Special Report No. 23), 617
Ions : Identification of Flavones by the Ultra-Violet Absorption Spectra of their (G. H. Mansfield, Dr. T. Swain and C. G. Nordstrom), 23
Ions (Ethoxide and Hydroxide) : Equilibrium between, in Ethanol (Dr. E. F. Caldin and G. Long), 583
Ions (Ferrous) Activation of Fumaric Hydrogenase by (K. Harrison), 509
Iphita limbata Stal . Thoracic Glands of (Dr K. K. Nayar), 768
Ireland Directory of Sources of Specialized Information in Great Britain and (Aslib), 613
    Index to Theses accepted for Higher Degrees in the Universities of Great Britain and (Aslib), Vol. I, 985
Ireland (Northern) Occurrence of the Enteropneust *Glossobalanus sarniensis* Koehler in (C. Edwards), 343
Irish National Committee for Geodesy and Geophysics, 142
Irish Sea Marine Biology in the, 58
    Occurrence of *Phoronis mülleri* in the (Eva C. Judges), 439
Iron at High Pressures The Melting of (Prof. F E. Simon), 746
Iron in Tunicin-forming Blood Cells of an Ascidian : Discovery of (R. Endean), 123
Iron Laminations at Magnetic Saturation : Alternating-Current Energy Losses in (Dr. P. Brailsford and C. G. Bradshaw), 35
$^{54}Fe(n,p)^{54}Mn$ Reaction (G. H. Stafford and L. H. Stein), 1103
Iron and Steel Institute : Annual General Meeting, 840
    Symposium on the Process of Sintering, 840
Iron and Steel Research Association, British Appointment of J. Savage as head of the Physics Department, 442
    New laboratories at Sheffield to be opened by the Duke of Edinburgh, 797
Irradiated Cytoplasm Action of, on Untreated Chromosomes of the Silkworm (Prof. Yoshio Nakao), 625
Irradiation of Hexavalent Chromium in an Atomic Pile Szilard and Chalmers Effect by (Dr. B. Ottar), 362
Irradiation of Polymers by High-Energy Electrons (E J. Lawton, A. M. Bueche and J. S Balwit), 76
Irregularities in the Rotation of the Earth : On the Geophysical Interpretation of (Walter Munk and Roger Revelle), 707
Irreversible Choline-esterase Inhibitor in White Clover (D. F. Heath and P. O. Park), 206
Irreversible Electrochemical Phenomena Thermodynamics of (Prof. S. R. de Groot, P. Mazur and H. A. Tolhoek), 497 ; (Peter H. Kemp), 498
Irritant Responses in Marine Fish : Relation of Chemical Structure to (Prof. Robert W Hiatt, Prof. John J. Naughton and Prof. Donald C. Matthews), 904
Irwin, Dr J. O. Statistical Method in Biological Assay, *review*, 925
Isaacs, Dr. A Nature and Constitution of Viruses, 106
Isaacs, N , and others Friedrich Froebel and English Education (edited by Evelyn Lawrence), *review* by Miss P. M. Pickard, 219
Isard, Walter, and Whitney, Vincent Atomic Power, an Economic and Social Analysis, *review* by B. L. Goodlet, 369
Iso-Immunization of Pregnancy : Hæmolytic Disease of New-born Pigs caused by (J. C Buxton and N. H. Brooksbank), 355
Isolating Soft-rotting Bacteria from Soils : A Method of (Allen Kerr), 1155
Isolation of Intertidal Animals by Sea Barriers (Dr. D. J Crisp and Dr. A. J. Southward), 208
Isolation of a Mixed Disulphide of Glutathione and Cysteinylglycine from a Partial Hydrolysate of Glutathione (Dr. Eskil Wikberg), 398
Isolation of a New Strain of *Plasmodium knowlesi* (Colonel Jaswant Singh, A. P. Ray and C. P. Nair), 122
Isolation of Penicillaminic Acid and D-*a*-Aminoadipic Acid from Cephalosporin *N* (G. G. F. Newton and Dr. E. P. Abraham), 395
Isolation of *l*-Quinic Acid from the Peach Fruit (E. F. L. J. Anet and T. M. Reynolds), 1188
Isolation of Thorium B (Lead)-binding Substance from the Erythrocytes of Rabbit Blood (Dr K. K. Reddi), 202
Isolation and Biochemical Function of the Golgi Substances (Dr. Walter C. Schneider, A. J. Dalton, Edward L Kuff and Marie Felix), 161
Isomer of Chlorogenic Acid from Peaches . A New (Joseph Corse), 771
γ-Isomer of Benzene Hexachloride in Cattle Dipping-Fluids Depletion of (W J. Roulston and L F Hitchcock), 546
Isomeric States of Molybdenum-93 (Prof. L. Katz and J. Goldemberg), 723
Isotope Abundance in Mercury : A Method of Changing the (E. Haeffner), 775
Isotopes (Radioactive) : Standardization of, in Great Britain (W. E. Perry), 1026
Isotopic Boron and Lithium from Nuclear Research Emulsions : Recovery of (M. L. Smith), 1054
Isotopic Spin Selection Rules (Dr. D. H. Wilkinson), 576
Isoxanthopterin (Prof. Adrien Albert and Dr. H. C. S. Wood), 118

Israel: New Erythrean Fishes from the Mediterranean Coast of (Dr. A. Ben-Tuvia), 464
Italian National Science Museum at Milan (W. T. O'Dea), 377
Italian Physical Society: International School of Physics, 146
Italian Society of Geophysics and Meteorology: Scholarship in Meteorology or Geophysics, 571
Itterbeek, Prof. A. van: Recent Developments in Ultrasonics and Optics, 443
Ivens, G. W.: Appointed senior scientific officer (botanist), Colonial Insecticide Research Unit, Tanganyika, 571
Ives, Dr. Herbert E.: Death of, 1081

Lillie, Dr. H. Oil Pollution of the Sea, 1026
Limnology Twelfth International Congress of (Prof F E. Fritsch), 888
Limnology, International Association of : Twelfth International Congress of Limnology, 888
  Election of Officers, 889
Limpet (*Crepidula fornicata*) The American Slipper, in Milford Haven (Dr. H A. Cole and R. H. Baird), 687
Lincoln, B. : Elastic Deformation and the Laws of Friction, 169, *erratum*, 234
Lind's Treatise on Scurvy, a Bicentenary Volume containing a reprint of the first edition of A Treatise of the Scurvy by James Lind, with additional Notes (edited by Dr. C. P. Stewart and Dr. Douglas Guthrie), 50
Lindegren, Prof. Carl C., and others : Heterosis in Saccharomyces, 800
Lindley, A. L. G. Appointed to the board of directors of the General Electric Co., Ltd., 101 ; work of, 101
Lindstrom, Dr. B , and others A Comparison between the X-Ray Absorption and Optical Interference Methods for the Mass Determination of Biological Structures, 1041
Linear Accelerator . Effect of Anomalous Attenuation in a (C. W. Miller and G. Saxon), 463
Linkage between Pulmonary Tumours and Vestigial Tail in the House Mouse (Dr. W. E. Heston), 1007
Linschitz, Dr. Henry, and Abrahamson, Edwin W. : Kinetics of Porphyrin-catalysed Chemiluminescent Decomposition of Peroxides, and the Mechanism of Photosensitized Oxidation, 909
Linser, Dr H. : Chemical Structure in relation to Plant Growth-Regulating Activity, 710
Lipase Pancreatic—a Scheme of its Specificity and a Hypothesis of the Mechanism of its Action (J. E. Scott), 777
'Lipase' in Gland Duct Epithelium and in Mucus-secreting Cells (B. F. Martin), 1048
Lipid Chemistry Progress in, *review* by Dr. J. A. Lovern, 740
Lipid Extractor : A Micro (Dr. Peter Mitchell), 124
Lipids : Biochemical Problems of (Royal Flemish Academy of Sciences Colloquium on), 573
  Progress in the Chemistry of Fats and other (edited by Prof. R. T. Holman, W. O. Lundberg and T. Malkin), Vol. 1, *review* by Dr. J. A. Lovern, 740
Lipmann, Dr. Fritz (Krebs, Prof. H A , and) : Awarded jointly the Nobel Prize for Medicine and Physiology for 1953, 837 ; work of, 837
Lipoid Pattern of the Adrenal Cortex of the Rat following Hypophysectomy : Changes in the Vascular and (J. D. Lever, Dr. D. B Cater and M. P. Stack-Dunne), 33
Lipshitz, Miss Rakoma, and others : Separation of Calf Thymus Deoxyribonucleic Acid into Fractions of Different Composition, 289
Lipson, Dr. H. : Imperfections in Metals, *review*, 266
Liquefier (Helium) A New Type of (H. M Long and Prof. F E. Simon), 581
Liquid Columns An Interferometer for Simultaneous Observation of Concentration and Concentration Gradient in (Dr. W. Weinstein), 461
Liquid Flow in Paper Electrophoresis : Reduction of (M A Jermyn and R. Thomas), 728
Liquid Scintillation Detectors : Determination of Total Body Radioactivity using (F. Reines, R. L. Schuch, C. L. Cowan, Jun., F. B. Harrison, E. C. Anderson and F. N. Hayes), 521
Liquids (Thick), Pastes and Slurries : The Mixing of (British Society of Rheology Symposium on), 384, 846
Listeria Infection in the Guinea Pig caused by Feeding with Aureomycin (Prof. Paavo Roine, Aune Raitio and Unto Vartiovaara), 767
Literature (Rubber) : Classification of, 144
Literature for an Age of Science (Prof Hyman Levy and Helen Spalding), *review* by W L Sumner, 49
Literature for the Medical Man Lighter, 101
Literature and Science : Lecture-recitals of sound-recordings in the study of Music, Drama, (British Institute of Recorded Sound, Ltd., in conjunction with the Department of Extra Mural Studies of the University of London), 526
Litherland, A E. Appointed by the Royal Society to a Rutherford Memorial Scholarship at the Atomic Energy of Canada, Ltd., Chalk River, Canada, 185
Lithium (Isotopic Boron and) : Recovery of, from Nuclear Research Emulsions (M L. Smith), 1054
Little, Dr K. : Use of Fission-Product Radiation, 148
Little, P. F Ionization Phenomena in Gases, 798
Little, W. A. : Awarded a Postgraduate Scholarship by the Shell Petroleum Co., Ltd., 485
Littlefield, Dr T. A : Recent Developments in Ultrasonics and Optics, 443
Littoral Molluscs Rate of Activity as a Function of Intertidal Height within Populations of some (Earl Segal, K Pampapathi Rao and Thomas W. James), 1108
Liver (Mouse) : Growth Cycle of Ectromelia Virus in (G J V. Nossal and Prof P M de Burgh), 671
Liver (Rat) Intracellular Distribution of Vitamin A Esterase Activity in (Dr. J Ganguly and Prof. H. J. Deuel, jun), 120
Liver of the Chicken Embryo : Glycogen in the Dividing Cells of the (R. J. O'Connor), 678
Liver Fluke, *Fasciola hepatica* L : Maturation and Probable Gynogenesis in the (Dr. Ann R. Sanderson), 110
Liversidge, Miss Joan Excavations at Margidunum, 192
Livesley, R. K. : Utilization of Digital Computing Machines in Engineering and Industry, 650
Livestock : Quality and Quantity of Protein for Man and (Dr. D. P. Cuthbertson), 434
Livestock (Britain's) Problems in providing Rations for (Scottish Group of the Nutrition Society Conference on), 844
Livestock (Farm) : Preventive Medicine among (British Association for the Advancement of Science, Section M (Agriculture), Discussion on), 561
Living Body (Prof. Charles Herbert Best and Prof. Norman Burke Taylor), third edition, *review* by Sir Charles Lovatt Evans, 4
Living Cells . Determination of Dry Mass, Thickness, Solid and Water Concentration in (Dr R. Barer), 1097
Living Organism . A Contribution to the Theory of the (Prof. W. E. Agar), second edition, *review*, 223
Livingstone, David . Statue of, unveiled at the Royal Geographical Society, 795
Lloyd, Geoffrey Use of Atomic Energy in Britain for Electrical Power, 894
Localization of Tobacco Mosaic Virus Antigen : Radioautographic Study of the (Dr. F. Gavosto and Mrs. A. Ficq), 406
Locher-Ernst, Prof. Louis . Einfuhrung in die freie Geometrie ebener Kurven, *review* by Prof. H. T. H. Piaggio, 269
Lochte Holtgreven, Prof. W. Ionization Phenomena in Gases, 798
Lochte Holtgreven, Prof W. and others : Production of Magnetic Fields in Liquid Mercury by Mechanical Motion, 1053
Lochte-Holtgreven, Prof. W. (Schilling, P , and) . Magnetic Fields measured within Flames brought mechanically into Rotational Motion, 1054
Lockley, R. M. . Puffins *review* by Frances Pitt, 375
Lockspeiser, Sir Ben Fifty Years of Powered Flight, 742
  New building for biochemical research at the Pest Infestation Laboratory opened by, 894
Locomotion of Animals, *review* by Dr L. Harrison Matthews, 698
Locust (African Migratory) : Possibility of Movements of the, in the Solitary Phase and the Dynamics of its Outbreaks (J. T. Davey), 720
Locust (Desert) (*Schistocerca gregaria* Forsk) (Acrididae) : Thelytokous Parthenogenesis for Four Generations in the (Dr. A. G. Hamilton), 1153
Locust Swarms (Flying) : Some Recent Developments in the Use of Aircraft against (Dr. R. C. Rainey and H. J. Sayer), 224
Locustana pardalina during Embryogenesis Activity of the Incretory Centres of—Function of the Prothoracic Glands (Dr. Bryn M Jones), 551
Locusts : Formation of Glucosides from Phenols in (Celia M. Myers and Dr. J. N. Smith), 32
  'Slow' and 'Fast' Nerve Fibres in (G. Hoyle), 165
Lodge, S. M. (Burrows, E M., and) : Culture of *Fucus* Hybrids, 1009
Löffler, Alfred, and Ginsburg, David : A New Synthesis of Carbazoles, 820
Logic : Methods of (Prof. Willard van Orman Quine), *review* by F. I. G. Rawlins, 884
Logic of Personality (Bernard Mayo), *review* by Prof. John Cohen, 698
Logic, Philosophy and Psychology of Business Decision-making under Uncertainty (British Association for the Advancement of Science, Section F (Economics), Symposium on), 701
Logic and Probability . Studies in (George Boole), *review* by S. A. S., 325
Logics . Many-valued (Prof. J. Barkley Rosser and Prof. Atwell R. Turquette), *review* by F. I. G. Rawlins, 928
London Mint : The, *review* by Prof F. C Thompson, 221
London School of Economics and Political Science Re-appointment of Sir Alexander Carr-Saunders as deputy vice-chancellor of the University of London, 18
  Title of reader in psychology in the University of London conferred on Dr. Hildegard T. Himmelweit, 1085
London School of Hygiene and Tropical Medicine Appointment of Dr. J H F. Brotherston to the University of London readership in public health, 103
  Title of reader in entomology, as applied to hygiene, in the University of London conferred on Dr. J. R. Busvine, 1085
London Town (Sir Henry Self), 476
London Weather : A Century of (W. A. L. Marshall), *review*, 1020
Long, G. (Caldin, Dr. E F , and) Equilibrium between Ethoxide and Hydroxide Ions in Ethanol, 583
Long, H. M., and Simon, Prof. F. E. : A New Type of Helium Liquefier, 581
Long, W M. (Bronowski, Dr. J., and) : The Australopithecine Milk Canines, 251
Long Ashton Research Station—Jubilee Celebrations (R. W. Marsh), 273
Longitudinal Elastic Waves in Cylindrical Rods (R E D. Bishop), 169
Loosemore, R. : Ionization Phenomena in Gases, 799
Lorand, Dr. L. 'Adenosine Triphosphate–Creatine Transphosphorylase' as Relaxing Factor of Muscle, 1181
Lord, Dr. K. A., and Potter, Dr. C. Hydrolysis of Esters by Extracts of Insects, 679
  Organo Phosphorus Insecticides, 944
Lord, Dr. Mary P. : Eye Movements in connexion with Television Viewing, 964
Lorentz, H. A. (1853–1928), 157
Loring, Hubert S., and others (edited by) Annual Review of Biochemistry, Vols 20 and 21, *review* by Prof F. G. Young, 928
Lorises : Comparative Anatomy and Taxonomy of the Lemurs and, *review* by Prof. S. Zuckerman, 880
Lort, W. R. V Appointed cultivation officer, Department of Science and Agriculture, Barbados, 753
Loudon, Dr. J. D : Organic Chemistry for the Honours Student, *review*, 135
Louis, Jean, et Fouarge, Joseph : Essences Forestieres et Bois du Congo, Fasc. 1, Introduction, 1177
Lousley, J. E. (edited by) The Changing Flora of Britain, 708
Love Waves in Earthquakes (Yasuo Sato), 280
Lovell, Prof. Bernard, and Clegg, Dr. J. A. : Radio Astronomy, *review* by J. A Ratcliffe, 47
Lovern, Dr. J. A. : Progress in Lipid Chemistry, *review*, 740
Low, A R. W. : Use of Atomic Energy in Britain for Electrical Power, 894
Low, Dr. Barbara W. Experimental Data and Model Structures for the Insulin Molecule, 1146
Low-Frequency Noise in the Range 0 5–20 cycles per sec. (Jules Aaron and Martha Henissart), 682

Low Pressures : Velocity of Sound in Air at (D. E. Caro and Prof. L. H. Martin), 363
Low Temperatures : Crystal Structure and Magnetic Properties of Cobalt Ferrite at (H. P. Rooksby and B. T. M. Willis), 1054
Lowe, D. N : Appointed secretary of the Carnegie United Kingdom Trust, 754, 794 ; work of, 794
Lowe, J. S., and others : Aspects of Vitamin A Deficiency in Rats, 716
Lowenstein, Prof. Otto · Protozoology, *review*, 323
  Effect of Galvanic Polarization on the Impulse Discharge from the Horizontal Ampulla of the Isolated Elasmobranch Labyrinth, 549
Lowes, Dr. F. J. : Magnetic Properties of the Earth's Interior, 787, *erratum*, 895
Lowndes, Dr. A. G. : Nosean as a Tracer Mineral, 636
Lowy, Dr. J. : Appointed lecturer in experimental zoology at Queen's University, Belfast, 1173
Loyalties : Conflicts of (Present Question Conference on), 1172
Lubbock, David (Boyd-Orr, Lord, with the co operation of) : The White Man's Dilemma, Food and the Future, *review*, 371
Lucas, Arthur, and Bromelle, Norman : Synthetic Materials in Picture Conservation, 752
Luck, J. Murray, and others (edited by) . Annual Review of Biochemistry, Vols. 20 and 21, *review* by Prof. F. G. Young, 928
Luckey, Dr. G. W. : Impurity Phenomena, 386
Lodenitz, D. : Biological Rhythms, 944
Ludlam, F. H. : Orographic Cirrus Clouds, 339
Luffa Plant and its Uses (J. S. Ingram), 612
Lugeon, Prof. M. : *Obituary* by Sir Edward Bailey, 891
Lukens, F. D. W. : Metabolic Influence of Insulin, 1073
Lumb, Dr. M. · Antibiotics, their Production and Use in Industry, 330
Luminescence (Electronics Group of the Institute of Physics Conference on), 796
Lumsden, Dr. T. W. : *Death of*, 1081
Lundbak, A : At the fourth meeting of the European Association of Exploration Geophysicists, 190
Lundberg, W. O., and others (edited by) : Progress in the Chemistry of Fats and other Lipids, Vol. I, *review* by Dr. J. A. Lovern, 740
Lundegårdh, Prof. H. : Complex Reactions of Cytochrome c, 303
Lundquist, Dr. Frank : Glycerophosphoryl Choline as a Precursor of Free Choline in Mammalian Semen, 587
Lundsgaard, Dr. E. : Honorary doctorate in science of McGill University conferred on, 1074
Lundy Field Society : Sixth Annual Report, 16
Lyman, C. P. : At the XIX International Physiological Congress, Montreal, 1073
Lynas, J : Physiology of Athletic Training, 936
Lynch, A. C. : Electrical Insulation, 9
Lyon, D. C. . Appointed assistant conservator of forests, Uganda, 1085
Lyon, G. : Triennial award of the Coopers Hill War Memorial Prize and Medal made by the Institution of Electrical Engineers to, 187
Lyons, Dr. Harold . High-Frequency Electrical Measurements, 52
Lyttelton, Oliver : Statue of David Livingstone at the Royal Geographical Society unveiled by, 795

MCBURNEY, Dr. C. B. M., and others · A Fossil Human Mandible from a Levalloiso-Mousterian Horizon in Cyrenaica, 889
Maccabaeans, Society of Meldola Medal for 1954, 840
McCain, C. C Elected a Salters' Scholar for 1953–54 by the Salters' Institute of Industrial Chemistry, 59
McCalla, A. G. · Elected a Fellow of the Royal Society of Canada, 1176
McCance, Prof. R. A. (Hervey, Dr. G. R., and) : Provisioning of Expeditions in the Field, 974
McCann, Neil Frank : Appointed agricultural adviser (technical) in the United States, 654
McCartan, Miss L. M. C. : Awarded a Nature Conservancy Research Studentship in Zoology, 708
McCleery, R. M. · Awarded a British Memorial Fund Fellowship of the State of Victoria, Australia, 59
Maccoll, Dr. Allan . Title of reader in chemistry in the University of London conferred on, 60
McCrea, Dr. J F. · Turbidity-reducing Activity of Influenza Virus and Receptor-destroying Enzyme on Sheep Submandibular Mucoid, 912, 1173
McCrea, Prof. W. H. . Jordan's Cosmology, *review*, 3
  Precision in Astrophysics, *review*, 924
MacDougall, Dr. John D. B. : Toxicity Studies on Silicone Rubber and other Substances, 124
McDowell, D. M. . Appointed a lecturer in civil engineering (hydraulics) at Queen's University, Belfast, 60
McElroy, Dr. William D., and others : Effect of Molybdenum Deficiency on Nitrate Reductase in Cell-free Extracts of *Neurospora* and *Aspergillus*, 34
MacEwan, Dr D. M. C. : Advances in Methods of Studying Clays, 288
McFadyean, Sir Andrew : Address at the Annual Conference of the Institute of Personnel Management, 1086
Macfadyen, W. A. : Sulphates in African Inland Waters, 595
Macfarland, I. MacL. : Appointed veterinary officer, Nigeria, 234
McFarlane, Dr. A. S. . Nature and Constitution of Viruses, 106
MacFarlane, Dr. G. G. Promoted a Deputy Chief Scientific Officer in the Scientific Civil Service, 657
McFarlane, J. . Appointed Hugh Wood Memorial Fellow in the Department of Mining in the University of Leeds, 895
McGill University, Montreal . Symposium on Microwave Optics, under the joint sponsorship of the Eaton Electronic Research Laboratory, of Commission VI of the International Scientific Radio Union in Canada and the United States, and the Electronic Research Directorate, Air Force Cambridge Research Center, U.S.A., 615
  Honorary doctorates in science conferred on Sir Henry Dale, Dr. E. Lundsgaard and Dr. W. R. Hess, 1074
McGill University and the Arctic Institute of North America : Fellowship and Scholarships for Arctic or Sub-Arctic Research, 1085
MacGinitie, Harry D. . Fossil Plants of the Florissant Beds, Colorado, 1090
Machine-Tool Industry of the U.S.S.R. : Research Development in the (W. G. Cass), 64
Machines : Calculating, *review* by Dr. V. Vand, 371
Machines à penser (Louis Couffignal), *review* by Dr. V. Vand, 371
McIlrath (William) Fellowship for research and teaching in Animal Husbandry (Commonwealth Scientific and Industrial Research Organization), 794
MacIntosh, F. C. : At the XIX International Physiological Congress, Montreal, 1072
MacIntyre, A. K. : Physiological Theories of Learning, 1074
Mackay, Donald, and others : Science and Faith To day, *review* by R. Brightman, 557
MacKay, Dr. D. M. : Cybernetics, 648
McKay, H. A. C. : Solutions of Electrolytes in Organic Solvents, 149
Mackay, J. H. : Appointed conservator of forests, Northern Rhodesia, 60
Mackay, M., and others : Albumin, an Unexpected Physiological Activity, 79
Mackay, Dr. M. E., and others : Susceptibility of the Guinea Pig to Pharmacological Factors from its own Serum, 714
McKenna, T. A. : Honorary degree of LL.D. of the University of Sheffield to be conferred on, 1085
Mackenzie, Dr. C. J. : International Co-operation in Science, 21
McKenzie, H. A. (Badger, Dr. G. M., and) : Bond-Orders in Aromatic Compounds, 458
Mackenzie, Dr. Robert C. : Advances in Methods of Studying Clays, 287, *erratum*, 1085
Mackey, Dr. S. : On leave for a year from the University of Leeds to go as professor of civil engineering at the Indian Institute of Technology at Kharagpur, 983
Mackinney, Gordon, and others (edited by) · Annual Review of Biochemistry, Vols. 20 and 21, *review* by Prof. F. G. Young, 928
Mackintosh, Dr. N. A. : A Whale-marking Expedition, 933
Mackworth, Dr. N. H. : Appointed director of the Applied Psychology Research Unit of the Medical Research Council, 278
  Physiology of Cold, 1074
Mackworth-Praed, C. W., and Grant, Capt. C. H. B. : Birds of Eastern and North Eastern Africa, *review* by Sir Landsborough Thomson, 92
McLaren, Anne : Protective Effect of Aged Vaccines on a Neurotropic Virus Infection in Mice, 38
McLaughlin, Dr. R. J. W. : Awarded a Leverhulme Research Grant for 1953, 17
McLean, D. : Interaction between Crystal Slip and Grain Boundary Movement, 300
  Plastic Deformation of Metals, 572
McLeod, James Archie (Wardle, Robert A., and) : The Zoology of Tapeworms, *review* by Dr. J. N. Oldham, 6
Macmillan, Comdr D. H. (Russell, R. C. H., and) : Waves and Tides, *review* by K. F. Bowden, 268
Macmillan, R. H. : An Introduction to the Theory of Control in Mechanical Engineering, *review* by Prof. J. Greig, 91
  Teaching of Mechanics in British Universities, 898
McMullen, M. J., and others . Sterilization of Timber with Methyl Bromide, 532
Macphail, M. S. : Elected a Fellow of the Royal Society of Canada, 1176
MacPherson, D. P. : Awarded a Leverhulme Research Grant for 1953, 17
McPhillips, J. (Breyer, Dr. B., and) : An Indirect Polarographic Determination of Calcium, 257
MacRae, T. P., and others : Structure of Wool, 673
Macroscopic Theory of Interference and Diffraction of Light from Finite Sources (Dr. W. Wolf), 535
McWeeny, Dr. R. : Recent Developments in Ultrasonics and Optics, 444
Maecker, H. · Ionization Phenomena in Gases, 798
Magma Basic, chilled against Acid Magma (Prof. L. R. Wager and Sir Edward Bailey), 68 ; (Dr. Doris L. Reynolds), 69
Magnesium · Slow-Neutron Scattering Cross-Sections of (P. A. Egelstaff and R. Jackson), 415
Magnetic Field Separation of Racemic Mixtures by Electrophoresis in a Strong Centrifugal or (Prof. Frederick C. Leadrum), 499
Magnetic Field in the E-Layer : Measurements of the Terrestrial (Dr. M. Cutolo), 774
Magnetic Fields measured within Flames brought mechanically into Rotational Motion (P. Schilling and Prof. W. Lochte-Holtgreven), 1054
Magnetic Fields in Liquid Mercury : Production of, by Mechanical Motion (P. Burhorn, H. Griem and Prof. W. Lochte-Holtgreven), 1053
Magnetic Materials of High Coercivity : New (Prof. L. F. Bates), 97
Magnetic Properties of Cobalt Ferrite at Low Temperatures . Crystal Structure and (H. P. Rooksby and B. T. M. Willis), 1054
Magnetic Properties of the Earth's Interior (British Association for the Advancement of Science, Section A (Mathematics and Physics), Discussion on), 786, *erratum*, 895
Magnetic Resonance Spectrograms (Nuclear) : A Rapid Method of obtaining (K. Taylor), 722
Magnetic Saturation : Alternating-Current Energy Losses in Iron Laminations at (Dr. F. Brailsford and C. G. Bradshaw), 35
Magnetic Study of Amethyst (M. Leela), 464
Magnetic Survey of the Pacific and other Oceans : Meteorological and (Dr. B. M. Cwilong), 839
Magnetically Attracted Bodies : Electrical Contact Resistance between (C. W. Wilman), 917
Magnetism : Nuclear (Prof. E. M. Purcell), 338
  Remanent, of Varved Clays from Sweden (D. H. Griffiths), 539
Magnetism (Reverse Thermo-remanent) : Origin of, of Igneous Rocks (Prof. T. Nagata, S. Akimoto and S. Uyeda), 630
Magnetization of Igneous Rocks : Self-Reversal of Thermo-remanent (Prof. Takesi Nagata), 850
Magni, Prof. G. E. : 'Sex-Ratio,' a Non-Mendelian Character in *Drosophila bifasciata*, 81
Magoun, H. W. : Postural Mechanisms, 1074
Magrath, D. I., and others : Structure of Adenylic Acids *a* and *b*, 1184
Mahalanobis, Prof. P. C. : Organization and Personality, 476
Mahler, Prof. K. : Abelian Modular Functions, *review*, 323
Mahlman, H. A. : Impurity Phenomena, 386
Maistre, C. D. le : *Obituary* by J. F. Stanley, 140
Maize . 'Affinity' in (Prof. D. G. Catcheside), 112 ; (Dr. Donald Michie), 113 ; (Mrs. M. E. Wallace), 113
  Indolepyruvic Acid in (Bruce B. Stowe and Prof. Kenneth V. Thimann), 764
  Pre-Columbian, in Africa (Dr. M. D. W. Jeffreys), 965
Maize Rust, *Puccinia polysora* Underw. : Resistance to the (W. R. Stanton and R. H. Cammack), 505

Makino, Katashi, and Rih-ching, Hong : Substances in Bone-Marrow Extract accelerating Coagulation of the Blood, 205
Makino, Katashi, and others : Orotic Acid as One of the Growth-factors of Mice, 914
Malachite Green : Reconstitution of Virus X-saturated Potato Varieties with (Dr. D. Norris), 816
Malarial Infections in *Anopheles gambiae* : Inter-relations between Filarial and (Dr. R. C. Muirhead-Thomson), 352
Malaya : Tree-Spotting in, *review* by Dr. N. L. Bor, 827
  Wayside Trees of (E. J. H. Corner), second edition, *review* by Dr. N. L. Bor, 827
Male Germ-Cells of *Vaginula maculata* : Golgi Bodies in the (Dr. M. D. L. Srivastava), 689 ; (Dr. John R. Baker), 690
Malkin, T., and others (edited by) : Progress in the Chemistry of Fats and other Lipids, Vol. 1, *review* by Dr. J. A. Lovern, 740
Mallick, Lieut.-Colonel S. M. K. : Medicine—a Technology or a Profession, 482
Mallyon, S. A. : 'Rabbit-Gait' in the House Mouse, 312
Mammalian Adaptive Enzyme System : Influence of Hypophysectomy and of Adrenocorticotropic Hormone on a (Dr. Irving I. Geschwind and Prof. Choh Hao Li), 732
Mammalian Blood : Formation of Thromboplastin in Shed (Dr. P. Fantl and R. A. Hayes), 303
Mammalian Enterochromaffin Cells : Detection of 5-Hydroxytryptamine in (Dr. R. Barter and Dr. A. G. Everson Pearse), 810
Mammalian Semen : Glycerophosphoryl Choline as a Precursor of Free Choline in (Dr. Frank Lundquist), 587
Mammals : Polyspermy in (C. R. Austin and A. W. H. Braden), 82
  Sub-Diploid Chromosome Variation in Man and other (Dr. Leo Sachs), 205
  Ventricular Nerve Cells in (Prof. G. A. G. Mitchell, R. Brown and F. B. Cookson), 812
Mammoth Hunters in Austria, 570
Man : Piltdown (Dr. J. S. Weiner, Dr. K. P. Oakley and Prof. W. E. Le Gros Clark), 981
  Race Crossing in (J. C. Trevor), *review* by Dr. H. Gruneberg, 137
  Toxic Hazards of Pesticides to (Dr. George C. Decker), 1125
  Utilization of Purines for Nucleic Acid Synthesis in (Dr. Leonard Hamilton), 457
Man's Dilemma : The White—Food and the Future (Lord Boyd-Orr, with the co-operation of David Lubbock), *review*, 371
Man (Fossil) : A New, from South Africa (Dr. J. C. Trevor), 652
Man (Modern) : Modern Science and (James B. Conant), *review* by R. Brightman, 557
Man and Animals : Chemotherapy of, *review* by Dr. R. A. Shooter, 644
  Organic Manures and Fertilizers and the Production and Composition of Food for (Section of Comparative Medicine of the Royal Society of Medicine Discussion on), 11
  The Sulphonamides and Antibiotics in (Dr. J. Stewart Lawrence and Prof. John Francis), second edition, *review* by Dr. R. A. Shooter, 644
Man and Livestock : Quality and Quantity of Protein for (Dr. D. P. Cuthbertson), 434
Man and other Mammals : Sub-Diploid Chromosome Variation in (Dr. Leo Sachs), 205
Man-power : Scientific, and Science-teaching, 1113
Management : Education for, 795
  Effect of Two Systems of, on Milk Yield and Body Temperature of Dairy Cattle (Dr. K. A. Alim), 1195
  Forest, *review* by Prof. H. M. Steven, 370
  Philosophy for (Triplex Safety Glass Co., Ltd., Booklet on), 612
  Training for (British Association for the Advancement of Science, Sections F (Economics) and L (Education), Discussion on), 693
Management, British Institute of : Annual Conference, 656
  Survey of Administrative Studies in Britain, 795
  Executive Development Programme, 796
Management of Forests : Planned (N. V. Brasnett), *review* by Prof. H. M. Steven, 370
Management under Nationalisation, Studies in Decentralisation (Acton Society Trust), 694
Managers for British Industry : Supply and Education of, 714
Managers (Industrial Directors and) : Report of the Third Conference of (Federation of British Industries), 757
Mandible : A Fossil Human, from a Levalloiso-Mousterian Horizon in Cyrenaica (Dr. C. B. M. McBurney, Dr. J. C. Trevor and Dr. L. H. Wells), 889
Manley, Prof. G. : Climatic Change, 1167
Manley, N. : Appointed meteorologist, Trinidad, 1085
Mann, Dr. Frederick George, and Saunders, Dr. Bernard Charles : Practical Organic Chemistry, third edition, *review* by Dr. C. Buchanan, 49
Manning, P. P. : Elected a Salters' Fellow for 1953–54 by the Salters' Institute of Industrial Chemistry, 59
Mannkopff, R. : Ionization Phenomena in Gases, 798
Manogue, B., and Moss, M. S. : Resistant Membranes from Wool and Hair Fibres, 806
Manoleon, P. : Appointed veterinary officer, British Honduras, 1085
Mansfield, G. H., and others : Identification of Flavones by the Ultra-Violet Absorption Spectra of their Ions, 23
Mansfield, W. W. : Effect of Surface Films on the Evaporation of Water, 1101

Measurement of Colonization and Survival of Soil *Fusaria* in Detached Plant Tissue (Dr. R. H. Stover), 465
Measuring Oxygen consumed in the Metabolism of Small Animals : A New Method of (Prof. V. Capraro), 815
Mechanical Engineering : An Introduction to the Theory of Control in (R. H. Macmillan), *review* by Prof. J. Greig, 91
Mechanical Engineers, Institution of : Presidential Address (A. Roebuck), 1088
Mechanical Motion : Production of Magnetic Fields in Liquid Motion by (F. Burhorn, H. Griem and Prof. W. Lochte-Holtgreven), 1053
Mechanics (Prof. J. L. Meriam), Part 2, Dynamics, *review* by Dr. R. E. D. Bishop, 973
Mechanics : Engineering, *review* by Dr. R. E. D. Bishop, 973
Mechanics in British Universities : Teaching of (R. H. Macmillan), 898
Mechanism of the Incorporation of Adenine into Adenosine Monophosphate (Murray Saffran and Eduardo Scarano), 949 ; A New Phosphokinase, 5-Phosphoribokinase (Eduardo Scarano), 951
Mechanism of Phage Action (Margaret A. Jesaitis and Walther F. Goebel), 622
Mechanism of Phosphorylation in the Respiratory Chain (Dr. E. C. Slater), 975
Mechanism of Photosensitized Oxidation : Kinetics of Porphyrin-catalysed Chemiluminescent Decomposition of Peroxides, and the (Dr. Henry Linschitz and Edwin W. Abrahamson), 909
Mechanisms and Industrial Processes : Automatic Control of, *review* by Prof. J. Greig, 91
Medawar, Prof. P. B., and others : 'Actively Acquired Tolerance' of Foreign Cells, 603
Medical Bulletin (May and Baker, Ltd), 101
Medical Man : Lighter Literature for the, 101
Medical Research in the United States (K. M. Endicott and E. M. Allen), 1172
Medical Research Council : Appointment of Dr. N. H. Mackworth as director of the Applied Psychology Research Unit, 278
  Report for the Year 1951–1952, 444
  Appointment of new members, 485
  Grant of £600 for the maintenance of a research worker and the expenses of research in microbiological chemistry in the Department of Biochemistry in the University of Leeds, 895
  Appointment of a Clinical Research Board, 1130
Medical Research Council (Laboratory Animals Bureau) : Memorandum on Myxomatosis in Rabbits, 1085
Medical and Veterinary Science, Institute of, Adelaide : Appointment of Dr. W. Roman as head of the Division of Biochemistry, 942
Medicine—a Technology or a Profession (Lieut.-Colonel S. M. K. Mallick), 482
Medicine : Preventive, among Farm Livestock (British Association for the Advancement of Science, Section M (Agriculture), Discussion on), 561
Medicine, Royal Society of : Jenner Medal awarded to A. T. Glenny, 794
  Wellcome Research Library to be opened by the Marquess of Salisbury, 942
Medicine, Royal Society of (Section of Comparative Medicine) : Discussion on Organic Manures and Fertilizers and the Production and Composition of Food for Man and Animals, 11
Medieval Science in Asia : Ancient and, *review* by Dr. Joseph Needham, 1018
Mediterranean Coast of Israel : New Erythrean Fishes from the (Dr. A. Ben-Tuvia), 464
Mediterranean Sea : Seismic Refraction Experiments in the Indian Ocean and in the (Dr. T. F. Gaskell and J. C. Swallow), 535
Medium-Energy Nuclear Physics (University of Pittsburgh Conference on), 527
Medullary Bone : Avian (T. G. Taylor and Dr. J. H. Moore), 504
Meek, J. M., and Saxe, Dr. R. F. : Ionization Phenomena in Gases, 798
Megaspores : A Stauropteris with two (K. R. Surange), 233
Meggy, Dr. A. B. : Dyeing and Tanning, 1031
Mehrotra, Dr. R. C. : Preparation of Aluminium Tri-Soaps, 74
Mehta, P. R., and others : Varietal Reaction of Jowar to Grain Smut, 591
Mela, P., and others : Glutamotransferase in the Chick Embryo during Incubation, 253
Melanophore Hormone : Effect of, on Regeneration of Visual Purple in Solution (Prof. Toshimasa Hanaoka), 866
Meldau, Dr. Robert, and Robertson, Robert H. S. : Thermal Decomposition of Dolomite, 998
Meldola Medal of the Society of Maccabaeans, 840
Mellanby, Sir Edward : Provisioning of Expeditions in the Field, 974
Melting of Iron at High Pressures (Prof. F. E. Simon), 746
Melts : The Physical Chemistry of (Institution of Mining and Metallurgy), *review* by Prof. F. C. Thompson, 1067
Meltzer, B. : Recent Research in Electron Optics, 61
Melville, L. G. : Appointed vice-chancellor of the Australian National University, Canberra, 103
Melville, R. V. : Treatise of Palaeontology, *review*, 560
Membrane Filter : Morphogenetic Interaction between Embryonic Mouse Tissues separated by a (Dr. Clifford Grobstein), 869
Membranes : Resistant, from Wool and Hair Fibres (B. Manogue and M. S. Moss), 806
Men of the Trees, Society of the : Summer Issue of the *Journal*, 484
Mendelssohn, Dr. K. : Superconductivity, 896
Meng, H. C. : At the XIX International Physiological Congress, Montreal, 1073
Menon, Dr. M. G. K. : Awarded a Senior Studentship for 1953 by the Royal Commission for the Exhibition of 1851, 17
Menon, M. K., and others : A Plasmodium in Common Indian Partridges, 687
Menstrual Cycle : Variations in the Content of Deoxyribonucleic Acid in the Human Uterine and Vaginal Receptors during the (R. Vokaer, Cl. Gompel and A. Ghilain), 31
Menter, J. W. : Recent Research in Electron Optics, 62
Mentzer, Dr. C. : Chemical Structure in relation to Plant Growth-Regulating Activity, 710
Menzel, Prof. Donald H. : Flying Saucers, *review* by Dr. C. E. P. Brooks, 220
Menzel, H. : At the fourth meeting of the European Association of Exploration Geophysicists, 190
Menzel, Prof. W. : Biological Rhythms, 943
Mercer, E. H. : Resistant Components of the Cortex of Animal Hair, 164
Merck and Co., Inc. : The Merck Index of Chemicals and Drugs, sixth edition, *review* by Prof. J. W. Cook, 220
Mercuric Oxychloride as Tri-chlormercury-oxonium Chloride (D. Grdenić and S. Šćavničar), 584
Mercury : A Method of Changing the Isotope Abundance in (E. Haeffner), 775
Mercury (Liquid) : Production of Magnetic Fields in, by Mechanical Motion (F. Burhorn, H. Griem and Prof. W. Lochte-Holtgreven), 1053
Meredith, F. W. : Awarded the Wakefield Gold Medal of the Royal Aeronautical Society, 381
Meredith, Prof. G. P. : Uncertainty, Expectation and Decision in Business Affairs, 701
Meredith, Dr. Sheila S. : Marine Biology in the Irish Sea, 58
Meriam, Prof. J. L. : Mechanics, Part 2, Dynamics, *review* by Dr. R. E. D. Bishop, 973
Merk, H. L., and others : Heat Transfer from Water to Ice by Thermal Convection, 460
Merry, A. O. : Appointed veterinary officer, Sarawak, 1085
Merseyside : A Scientific Survey of (edited by Prof. Wilfred Smith, assisted by F. J. Monkhouse and H. R. Wilkinson), *review*, 420
Mesenchymal Cells of the Tail Tip of *Rana pipiens* Tadpoles : Regular Occurrence of the Haploid Number of Chromosomes in (Dr. Elizabeth Ufford Green), 766
Mesomeric Effect of the Sulphonic Acid Group (Dr. Hch. Zollinger), 257
Mesomorphic and Polymorphic Transition Temperatures : A Heating Instrument for the Accurate Determination of (Dr. G. W. Gray), 1137
Mesoplodon europaeus, Gervais : First Record of the Rare Beaked Whale, from the West Indies (J. J. Rankin), 873
Messier 81 (Spiral Nebula) : Radio-Frequency Radiation from the (R. Hanbury Brown and C. Hazard), 853
Meta-aminophenol : Structure of (M. N. Dutt), 498
Metabolic Products of *Aspergillus nidulans* : Nidulin and 'Ustin', Two Chlorine containing (Dr. F. M. Dean, Prof. A. Robertson, Dr. John C. Roberts and Dr. K. B. Raper), 344
Metabolic Response to Injury : Cortisone and the (Rosa M. Campbell, Gillian Sharp, A. W. Boyne and Dr. D. P. Cuthbertson), 158
Metabolism : Tryptophane, in Rice Moth Larva (*Corcyra cephalonica* St.), (T. K. Sundaram and P. S. Sarma), 627
Metabolism (Acid) : Zymasis and, in Higher Plants (Dr. S. L. Ranson), 252
Metabolism (Nitrogen and Phosphorus) : Some Effects of Mosaic Virus on, in Tobacco Plants (Dr. Rupert J. Best and H. P. C. Gallus), 347
Metabolism (Tryptophan) : A Disturbance of, in Congenital Hypoplastic Anaemia (Prof. K. I. Altman and Gerald Miller), 868
Metabolism of Small Animals : A New Method of measuring Oxygen consumed in the (Prof. V. Capraro), 815
Metabolism Studies (Soil) : Use of the Warburg Apparatus in (A. D. Rovira), 29
Metabolites : Tryptophane, in Human Urine (Dr. M. Špaček), 204
Metal : Quantitative Paper Chromatography of Traces of, with the Aid of Radioactive Hydrogen Sulphide (P. C. van Erkelens), 357
Metal Finishing, Institute of : Election of Officers for 1953–54, 336
  Westinghouse Brake and Signal Co., Ltd., Prize for 1952–53 awarded jointly to Dr. A. E. Davies, R. M. Angles and Dr. J. W. Cuthbertson, 656
  Hothersall Memorial Lecture for 1953–54 (Dr. William Blum), 754
Metal Physics : Progress in (edited by Dr. Bruce Chalmers), Vol. 3, *review* by Dr. R. W. K. Honeycombe, 94
  Progress in (edited by Dr. Bruce Chalmers), Vol. 4, *review* by Dr. W. Hume Rothery, 223
Metallic Cations : Avidity of Terramycin and Aureomycin for (Prof. Adrien Albert), 201
Metallic Complex Formation : A Colorimetric Method based on, for the Detection of Aureomycin in presence of Amino-Acids and Proteins (Dr. A. E. Oxford), 395
Metallic Films : Thin, for Anti-Reflexion Coatings on Dielectric–Air Interfaces (F. H. Smith), 462
Metallurgists, Institution of : Platinum Metals Exhibition to be opened by the Duke of Edinburgh, 384
  The Metallurgy of the Rarer Metals, *review* by Prof. F. C. Thompson, 1067
Metallurgy : Research Fellowship in (Established by the United Steel Companies, Ltd., in the University of Sheffield), 753
Metallurgy (Modern) : Aspects of, *review* by Prof. F. C. Thompson, 1067
Metallurgy of the Rarer Metals (Institution of Metallurgists), *review* by Prof. F. C. Thompson, 1067
Metals : Imperfections in, *review* by Dr. H. Lipson, 266
  Plastic Deformation of (Conference at the University of Bristol), 572
  The Platinum (A. R. Powell), 700
Metals, Institute of : Equipment for the Thermal Treatment of Non-Ferrous Metals and Alloys, *review* by Prof. F. C. Thompson, 1067
  Medal Awards for 1954, 1173
Metals (Bearing) : Score Resistance of (Arvid E. Roach, Carl L. Goodzeit and Paul A. Totta), 301
Metals (Rarer) : The Metallurgy of the (Institution of Metallurgists), *review* by Prof. F. C. Thompson, 1067
Metals and Alloys (Non-Ferrous) : Equipment for the Thermal Treatment of (Institute of Metals), *review* by Prof. F. C. Thompson, 1067
Metamathematics of Algebra : On the (Prof. Abraham Robinson), *review*, 137
Metcalfe, C. E. : Appointed agricultural officer, Nigeria, 1085
Metcalfe, Dr. C. R. : Effects of Atmospheric Pollution on Vegetation, 659

Meteor Spectrum · The Typical Perseid (Dr. Peter M. Millman), 853
Meteor Streams · Comets and (Dr. J. G. Porter), *review* by Dr. M. Davidson, 883
Meteor Streams in 1952 Radio Echo Observations of the Daytime (Mary Almond, K. Bullough and G. S. Hawkins), 751
Meteorites : Production by Cosmic Rays of Helium-3 in (Prof. F. A. Paneth, Dr P Reasbeck and Dr K I Mayne), 200
Meteorites and their Ages . Cosmic-Ray Production of Helium in (Dr. J. C. Dalton, Prof. F. A. Paneth, Dr. P. Reasbeck, Dr. S. J. Thomson and Dr. K. I. Mayne), 1168
Meteorological Conference (American Meteorological Society, the Royal Meteorological Society and the Canadian Branch of the Royal Meteorological Society), 103
Meteorological Conference at Toronto (Prof. P. A. Sheppard), 1166

Natural Conditions . Control of a Seed-borne Disease by *Chaetomium cochliodes* Pall., under (M. Tvert), 39
Natural History of Infectious Disease (Sir Macfarlane Burnet), second edition, *review* by Sir Philip Manson-Bahr, 927
Natural Knowledge : The Growth of (Dr. E. D. Adrian), 1023
Natural Philosophy at Edinburgh, 1882
Natural Radiocarbon : Use of an Acetylene-filled Counter for (Dr. A. R. Crathorn), 632
Naturalist : The Country, *review* by L. J. F. Brimble, 324
Naturalist in Southern Ethiopia (R. E. Moreau and E. Milne-Redhead), 388
Nature . A New Method of Estimating the Survival-Rate of Anopheline Mosquitoes in (C. C Draper and G. Davidson), 503
  Occurrence in, of an Alternative Host (*Leersia hexandra* Sw.) of *Helminthosporium oryzae* Breda de Haan (Dr. S. B. Chattopadhyay and N K. Chakraborti), 550
Nature of Culture (A. L. Kroeber), *review* by Dr. Paul Bohannan, 972
Nature Conservancy : New Nature Reserves, 15
  Awards of Research Studentships, 708
Nature Reserves in Britain · New, 15
Nature and Constitution of Viruses (Society for Visiting Scientists Symposium on), 105
Naughton, Prof. John J., and others Relation of Chemical Structure to Irritant Responses in Marine Fish, 904
Naumann Medals of the International Association of Limnology awarded to Prof. Lenz and Dr. L. Findenegg, 889
Naval Research, United States Office of, and others : Symposium on Plasticity, 17
Naval Research, United States office of, and the University of Pennsylvania . Symposium on the Origins of Resistance to Drugs, 754
Navigation, Institute of : Election of Officers for 1953–54, 753
Nayar, Dr. K. K. : Thoracic Glands of *Iphita limbata* Stal., 768
Neale, A. J. (Baker, Dr. J. W., and) : Importance of Ion Exchange with the Solvent in Kinetic Studies, 583
Neave, R M. S. · Appointed chief veterinary officer, Cyprus, 753
Nebula Messier 81 : Radio-Frequency Radiation from the Spiral (R. Hanbury Brown and C. Hazard), 853
Needham, Dr. James · An Introduction to Embryology, *review*, 739
  Agricultural Sanitation in Asia, *review*, 826
  Ancient and Medieval Science in Asia, *review*, 1018
  Biological Philosophy, *review*, 1119
Needham, L. W : Appointed an honorary lecturer in mineral dressing and coal preparation in the University of Leeds, 895
Néel, Prof. L · Elected a non-resident member of the Paris Academy of Sciences, 183
Negresco, P. E. : *Death of*, 750
Negri Bodies in Histological Brain Sections : A Selective Method for the Staining of (Dr. L Zlotnik), 962
Nematacea, a Moss Family New to Australia (J. H. Willis), 127
Neoplasia . Œstrogens and (Harold Burrows and Eric S. Horning), *review* by Prof. W. S. Bullough, 1066
Nerve Cells · Ventricular, in Mammals (Prof. G. A. G. Mitchell, R. Brown and P. B. Cookson), 812
Nerve Fibres in Locusts : 'Slow' and 'Fast' (G. Hoyle), 165
Nervous Activity : Physics and Physiology of, *review* by Prof. D. Whitteridge, 515
Nervous System : Research in Psychiatry, and the Biochemistry and Pharmacology of the (Grant of £28,000 from the Rockefeller Foundation of New York to the Department of Experimental Psychiatry of the University of Birmingham), 145
Nervous System (Central) : Thyroid Hypofunction and the Development of the (Dr. J. T. Eayrs), 403
Nests : Finding (Bruce Campbell), *review* by Frances Pitt, 828
Network Analysis : General (Prof. Wilbur R. LePage and Prof. Samuel Seely), *review* by Prof. H. T. H. Piaggio, 325
Neuberger, Dr. A., and Scott, J. J. : Aminolævulinic Acid and Porphyrin Biosynthesis, 1093
Neumann, Dr. B. S. : Advances in Methods of Studying Clays, 289
Neumann, Dr. Gert, and others : Factors modifying the Influence of Light on Germination, 452
Neumark, Dr. S. : Promoted a Senior Principal Scientific Officer in the Scientific Civil Service, 658
Neurofibrils in the Brain of a Human Foetus 28 Weeks Old : Formation of (M. C. H. Dodgson), 404
Neurohæmal Organs in Crustaceans (David B. Carlisle and Dr. Francis G. W. Knowles), 404
Neurohypophysis (Posterior Pituitary Gland) : Reflex Stimulation of the, and the Nature of Posterior Pituitary Hormone(s), (Prof. G. W. Harris and Dr. V. R. Pickles), 1049
Neurophysiological Basis of Mind (Prof. John Carew Eccles), *review* by Prof. D. Whitteridge, 515
Neurophysiology (Clinical) Third International Congress of Electroencephalography and, 145
Neurospora and *Aspergillus* : Effect of Molybdenum Deficiency on Nitrate Reductase in Cell-free Extracts of (D. J. Donald Nicholas, Alvin Nason and Dr. William D. McElroy), 34
Neurotic Illness in Twins · Psychotic and (Eliot Slater, with the assistance of James Shields), *review* by Dr. Clifford Allen, 739
Neurotropic Virus Infection in Mice : Protective Effect of Aged Vaccines on a (Anne McLaren), 38
Neutron Diffusion : Basic Methods in Transfer Problems—Radiative Equilibrium and (V Kourganoff, with the collaboration of I. W. Busbridge), *review* by Prof. W. H. McCrea, 924
Neve, R. A. (Bowden, J , and)· Sorghum Midge and Resistant Varieties in the Gold Coast, 551
New Zealand : Earthquakes in, during 1951 (R. C Hayes), 233
New Zealand Antarctic Society (A Mid-Century Survey by the) : The Antarctic Today (edited by Frank A. Simpson), *review* by J. D. M. Blyth, 372
New Zealand Department of Scientific and Industrial Research : Appointment of L. W. Tiller and I. D. Dick as assistant secretaries, 333
Newble, G. M. : Appointed meteorologist, Nigeria, 1085
Newbound, R. : Electrical Insulation, 11
Newcombe, Dr. A. G., and Reid, Dr. S. G. : Chromatographic Separation, using Chemically Treated Paper, of Aldehydes and Ketones on the Basis of their Reactivity, 455
Newhook, F. J , and Davison, R. M. · Combined Hormone-Fungicide Sprays for Control of *Botrytis* Fruit-Rot in Glasshouse Tomatoes, 351
Newitt, Prof. D. M. : Hydrodynamical Theory of Detonation and Shock Waves, *review*, 699
  Superconductivity, 896
Newman, J F : Organo-Phosphorus Insecticides, 946
Newman, J. F., and others : Amount of Gamma-Benzene Hexachloride picked up by Resistant Houseflies bred on a Medium containing Benzene Hexachloride, 1052
Newman and Science (Prof. T. S. Wheeler), 530
Newman, John Henry, and Science (W. L. Sumner), 530
Newman, L. H., and others · An Unknown Acid from Brain Extracts Chromatographed on Silica Gel, 1191
Newman, Prof. M. H. A. : Elements of the Topology of Plane Sets of Points, second edition, *review* by Dr. R. G. Cooke, 325
Newman, R. P. : Appointed chief administrative officer of the Engineering Research Station of the British Welding Research Association, 656
Newt's Eggs · Transplantation of Nuclei in (Prof. C. H. Waddington and E. H. Pantelouris), 1050
Newton, B. A. : Reversal of the Antibacterial Activity of Polymyxin by Divalent Cations, 160
Newton, G. G. F., and Abraham, Dr. E. P. · Isolation of Penicillaminic Acid and D-α-Aminoadipic Acid from Cephalosporin *N*, 395
Newton, Isaac · Gregory's 'Notæ in Isaaci Newtoni Principia Philosophiæ' (Dr. William P. D. Wightman), 690
Newton, Prof. Lily A Fresh Approach to Intermediate Botany, *review*, 882
Nicholas, D. J. Donald, and others . Effect of Molybdenum Deficiency on Nitrate Reductase in Cell-free Extracts of *Neurospora* and *Aspergillus*, 34
Nicholls, Dr. J. R. : Organo-Phosphorus Insecticides, 945
Nickels, K. : Chemical Processes and Chemical Engineering Techniques, 711
Nicotine : Biogenesis of (Dr. K. Bowden), 768
Nicotine, Tropane and Hygrine Bases : A Possible Common Biogenetic Origin of the (P. I. Mortimer), 74
Nidulin and 'Ustin', Two Chlorine-containing Metabolic Products of *Aspergillus nidulans* (Dr. F. M. Dean, Prof. A. Robertson, Dr. John C. Roberts and Dr. K. B. Raper), 344
Nield, P., and others : Amount of Gamma-Benzene Hexachloride picked up by Resistant Houseflies bred on a Medium containing Benzene Hexachloride, 1052
Nigerian Forest Administration · Annual Report for 1950–51, 382
Nigrosine : Application of, to the Study of the Salivary Chromosomes (Ramon Pardé), 1151
Nijkamp, H. J. : A Simple Chromatographic Method for the Determination of the C_{14}–C_{24} Saturated Straight-Chain Fatty Acids, 1102
Nilakantan, Dr. P. : Elected president of the Rajasthan Academy of Sciences for 1953–54, 613
Ninhydrin on Keratin : Action of (R. Cockburn, Dr. L. G. Jagger and Prof. J. B. Speakman), 75
Ninhydrin Reaction for the Determination of Amino-Acids · Influence of Cations on the (Dr. Hanan Meyer and Emanuel Riklis), 543
Nitrate (Lead) : Photo-elastic Effect in (Dr. S. Bhagavantam and K. V. Krishna Rao), 415
Nitrate Reductase in Cell-free Extracts of *Neurospora* and *Aspergillus* Effect of Molybdenum Deficiency on (D. J. Donald Nicholas, Alvin Nason and Dr. William D. McElroy), 34
Nitric Oxide : Reaction of, with Gaseous Hydrocarbon Free Radicals (H. T. J. Chilton and Dr. B. G. Gowenlock), 73
Nitrites (Organic) : Hydrolysis of (A. D. Allen), 301
Nitrocellulose–Water Gels : Dielectric Properties of (Dr. Hugo Fricke), 1106
Nitrogen (Microbial) : Conversion of Plant Nitrogen to, in the Rumen of the Sheep (F. V. Gray, A. F. Pilgrim and R. A. Weller), 347
Nitrogen (Plant) · Conversion of, to Microbial Nitrogen in the Rumen of the Sheep (F. V. Gray, A. F. Pilgrim and R A. Weller), 347
Nitrogen in the Life of Plants (Dr. Dimitrii Prianishnikov), translated by S. A. Wilde, *review* by Prof. A. C. Chibnall, 513
Nitrogen in Plants . Role of, *review* by Prof. A. C. Chibnall, 513
Nitrogen-13 · Half-value Periods for the Decay of Aluminium-26, Aluminium-25 and (J. L. W. Churchill, W. M. Jones and S. E. Hunt), 460
Nitrogen Heterocycles : Polycyclic, *review* by Prof. J. W. Cook, 882
Nitrogen Molecules · Recombination Coefficient in the *F*-Regions—a Possible New Process of Ionization of (R. B. Banerji), 953
Nitrogen Mustard . Influence of Cysteinamine, Methylamine and Cortisone on the Toxicity and Activity of (Dr. O. Peczenik), 454, *erratum*, 942
Nitrogen Trichloride : Explosions in Mixtures of Hydrogen, Chlorine and (Dr. P. G. Ashmore), 449
Nitrogen and Phosphorus Metabolism in Tobacco Plants : Some Effects of Mosaic Virus on (Dr. Rupert J. Best and H. P. C. Gallus), 347
Nitrosyl Chloride : Compounds of Tertiary Amines with, and with Dinitrogen Tetroxide (Dr. Alan E. Comyns), 491
Nobel Prize for Chemistry for 1953 awarded to Prof. Herman Staudinger, 893
Nobel Prize for Medicine and Physiology for 1953 awarded jointly to Prof. H. A. Krebs and Dr. Fritz Lipmann, 837
Nobel Prize for Physics for 1953 awarded to Prof. F. Zernicke, 938
Nodule Formation : Mutual Inhibitory Effects in (P. S. Nutman), 570
Noise : Low-frequency, in the Range 0·5–20 cycles per sec. (Jules Aaron and Martha Hennssart), 682
Noise-Burst (Radio) : Eruptive Prominence of February 26, 1953, and Associated (Dr. K. Das and K. Sechamadhavan), 446; Radio Observations at the Time of an Ascending Solar Prominence (R. D. Davies), 447
Noise-bursts : Radio, from Solar *M*-Regions (Dr. A. K. Das and B. N. Bhargava), 855

Nombres : La définition des, par leur valeur numérique et par leur origine—rôle de ce concept en philosophie mathématique (Prof. D. Riabouchinsky), 752
Nomenclature . Zoological—Amendments to the International Code of Zoological Nomenclature (Francis Hemming), 830, 966, 1010
Nomenclature of *cyclo*Hexane Bonds (Prof D. H. R. Barton, Prof. O. Hassel, Prof K. S. Pitzer and Prof. V Prelog), 1096
Non-geometrical Perspective in the Two dimensional Representation of Solid Objects : Use of (Philip Short), 1002
Non-Identity of Intermedin and Adrenocorticotrophic Hormone (Prof. A. O. M. Stoppani, P. F. Pieroni and A. Murray), 547
Non-Mendelian Character in *Drosophila bifurcata* : 'Sex Ratio', a (Prof. G. E Magni), 81
Non-standard Radio Propagation (P. G. Forsyth), 966
Noradrenaline and Hydroxytyramine in Extracts from Insects : Adrenaline, (Dr. Eric Östlund), 1042
Norbury, Christopher P. Address at the Jubilee Celebrations of the Long Ashton Research Institute, 274
Nordstrom, C. G., and others · Identification of Flavones by the Ultra-Violet Absorption Spectra of their Ions, 23
Normand, Sir Charles Atmospheric Ozone and the Upper-Air Conditions, 241
  Ozone and the High Atmosphere, 1166
  Elected an honorary member of the American Meteorological Society, 1168
Norris, Dr. D. . Reconstitution of Virus X-saturated Potato Varieties with Malachite Green, 816
Norrish, Prof. R. G. W., and others · Chemiluminescent Phenomena during Hydrocarbon Combustion, 71

Phillips, C. E. : Plastic Deformation of Metals, 572
Philology and the 'Kon-Tiki' Theory : Comparative (Prof. Alan S. C. Ross), 365
Philology and Polynesian Studies : Comparative (Prof. Alan S. C. Ross), 661
Philosophie mathématique : La définition des nombres par leur valeur numérique et par leur origine—role de ce concept en (Prof. D. Riabouchinsky), 752
Philosophy : Biological, *review* by Dr. Joseph Needham, 1119
Philosophy, Royal Institute of : Lecture programme for 1953–54, 656
Philosophy for Management (Triplex Safety Glass Co., Ltd., Booklet on), 612
Philosophy of Numbers, 752
Philosophy of Science, British Journal for the : Special Berkeley Number, 326
Philosophy and Psychology of Business Decision-making under Uncertainty : Logic, (British Association for the Advancement of Science, Section F (Economics), Symposium on), 701
Phloem Sap : Amino-Acids in, and their Excretion by Aphids (T. E. Mittler), 207
Phoronis mulleri in the Irish Sea : Occurrence of (Eve C. Judges), 409
Phosphatase (Alkaline) : Mode of Action of Beryllium on (Th. A. Veerkamp and G. Smits), 589
Phosphatase Activity (Alkaline) : Extremely High, in the Vaginal Mucus of the Cow (Dr. G. A. van Klinkenberg), 397
Phosphate Absorption and Utilization by Barley (R. Scott Russell and R. P. Martin), 335
Phospholonase : A New, 5-Phosphoribolonase (Eduardo Scarano), 951
5-Phosphoribolonase : A New Phospholonase (Eduardo Scarano), 951
Phosphorus Metabolism in Tobacco Plants : Some Effects of Mosaic Virus on Nitrogen and (Dr. Rupert J. Best and H. P. C. Gallus), 347
Phosphorus-32 : Mutagenic Possibilities of (W. R. Stanton and W. K. Sinclair), 484
Phosphorylation in the Respiratory Chain : Mechanism of (Dr. E. C. Slater), 973
Photochemical Oxygen Production from Isolated Algal Chloroplast Fragments (Dr. Thomas Punnett and Dr. Akinyele Fabiyi), 947
Photo-elastic Effect in Lead Nitrate (Dr. S. Bhagavantam and K. V. Krishna Rao), 415
Photoelasticity : Designing by (Dr. R. B. Heywood), *review* by E. K. Frankl, 926
Photoelasticity and Engineering Design, *review* by E. K. Frankl, 926
Photoelectric Raindrop Spectrometer (B. J. Mason and R. Ramanadham), 1176
Photoelectric Spectrophotometer at Kodaikanal Observatory : Recording (A. K. Das, R. Ananthakrishnan and B. N. Bhargava), 383
Photographic Society, Royal : International Conference on the Science and Applications of Photography, 145, 1121
Photography : Science and Applications of (Royal Photographic Society International Conference on), 145, 1121
Photography of Interference Fringes : Use of High Contrast in the (J. M. Hough and B. J. Goldsmith), 1105
Photomultipliers : Current Types of (Dr. W. E. Turk), 279
Detection and Recording of Optical Transients by (Dr. R. F. Saxe), 1198
Photoneutron Effect : An Analysis for Deuterium based on the (Dr. C. P. Haigh), 359
Photosensitized Oxidation : Kinetics of Porphyrin-catalysed Chemiluminescent Decomposition of Peroxides, and the Mechanism of (Dr. Henry Linschitz and Edwin W. Abrahamson), 909
Photosensitized Oxidation of Alcohols (J. L. Bolland and H. R. Cooper), 413
Phylloglossum drummondii, Kunze : Chromosomes of (M. Blackwood), 591
Physical Applications of High-Speed Rotation, 22
Physical Conditions : Soil, and Plant Growth (compiled by the Joint Committee on Soil Tilth, American Society of Agronomy, American Society of Agricultural Engineers, edited by Byron T. Shaw), *review* by Dr. H. L. Penman, 48
Physical Constants : Qualitative Organic Micro-analysis based on—Identification of Amino-Acids (Dr. A. Lacourt, G. Sommereyns, C. Francotte and N. Delande), 906
Physical Society : Report for 1952, 21
Symposium on Recent Research in Electron Optics, 61
Seventh Charles Chree Medal and Prize awarded to Prof. J. Bartels, 442
Summer Provincial Meeting on Recent Developments in Ultrasonics and Optics, 443
Thirty-eighth Annual Exhibition of Scientific Instruments and Apparatus, 571
Physical Society (Low Temperature Group) : Discussion on Superconductivity, 896
Physical Society, and others : Report of the Joint Committee on Infra-red Spectra, 795
International Conference on Ionization Phenomena in Gases, 798
Physical Standards : Maintenance of, 335
Physical Systems : Heat Transfer Phenomena, the Flow of Heat in (Dr. R. C. L. Bosworth), *review*, 375
Physicians of Philadelphia, College of : Alvarenga Prize for 1953 awarded to Dr. F. D. Moore, 146
Physico-Chemical Properties : Hydration Structure of Deoxyribonucleic Acid and its (Dr. Bertil Jacobson), 666
Physics : Developments in, *review* by S. Weintroub, 559
High-Energy, *review* by Prof. J. C. Gunn, 472
International School of (Italian Physical Society), 146
Medium-Energy Nuclear (University of Pittsburgh Conference on), 527
Nuclear (Conference in the University of Birmingham), 59
Reports on Progress in, Vol. 15, 1952 (executive editor, A. C. Stickland), *review* by S. Weintroub, 559
Soil, in Agronomy, *review* by Dr. H. L. Penman, 48
Theoretical Nuclear (Prof. John M. Blatt and Prof. Victor F. Weisskopf), *review* by Dr. K. J. Le Couteur, 785
A University Text-Book of, Vol. 3, Heat, being the eleventh edition and a largely rewritten version of Poynting and Thomson's 'Text-Book of Physics', Vol. 3 (J. H. Awbery), *review* by H. L., 1069
Physics in Queen Mary College, London, 100
Physics (Metal) : Progress in (edited by Dr. Bruce Chalmers), Vol. 3, *review* by Dr. R. W. K. Honeycombe, 94
Progress in (edited by Dr. Bruce Chalmers), Vol. 4, *review* by Dr. W. Hume-Rothery, 223
Physics (Theoretical) : International Conference on—Meeting in Japan (Prof. N. F. Mott), 886
Physics, Institute of : Annual General Meeting, 242
Election of Officers, 242
Physics, Institute of (Electronics Group) : Conference on Luminescence, 796
Physics, Institute of (X-Ray Analysis Group) : Annual Conference and Exhibition of X-Ray Crystallographic Equipment, 336, 656
Physics, Institute of, and others : International Conference on Ionization Phenomena in Gases, 798
Physics (Pure and Applied), International Union of, and others : Conference on Optics and Microwaves, 102
Physics of Fibrous Materials (Dutch Physical Society Symposium on), 144
Physics beyond General Physics for Non-Physics Majors (American Association of Physics Teachers Discussion on), 339
Physics of the Ionosphere, *review* by C. M. Minnis, 514
Physics of Synthetic Fibres : Chemistry and (Plastics and Polymer Group of the Society of Chemical Industry Symposium on), 656
Physics and Chemistry : Impurity Phenomena in (W. Gratidge), 385
Physics and Physiology of Nervous Activity, *review* by Prof. D. Whitteridge, 515
Physiological Activity : Albumin, an Unsuspected (M. W. Blewett, Sir Alan Drury and M. Mackay), 79
Physiological Approach to the Lower Animals (Dr. J. A. Ramsay), *review* by Dr. J. A. Kitching, 92
Physiological Congress, Montreal : XIX International (Dr. W. L. M. Perry), 1071
Physiological Phenomenon in the Human Electroencephalogram : The Lambda Wave as a Normal (Dr. Martin Roth and Joy Green), 864
Physiological Races of Wheat Stem Rust in Egypt (Dr. T. Abdel-Hak), 802
Physiological Sciences, International Union of : Formation of an, 1074
Physiology : Adventures in (a Selection from the Scientific Publications of Sir Henry Hallett Dale), *review* by Prof. J. H. Gaddum, 825
Post-doctoral Fellowships in Biochemistry, Biophysics and (Lalor Foundation), 1085
Physiology' ('Animal) : Applications of, to Agriculture (Dr. John Hammond), 437
Physiology (Human) : Introduction to, *review* by Sir Charles Lovatt Evans, 4
Physiology of Athletic Training (British Association for the Advancement of Science, Section I (Physiology), Symposium on), 934
Physiology of Lower Animals : Comparative, *review* by Dr. J. A. Kitching, 92
Physiology of Nervous Activity : Physics and, *review* by Prof. D. Whitteridge, 515
Physiology of Song in Cicadas (Dr. J. W. S. Pringle), 248
Phytophthora fragariae : A New Method for testing the Pathogenicity of (Dr. C. J. Hickman and Pamela M. Goode), 211
Phytogeographical Excursion : Tenth International (Prof. P. W. Richards), 566
Pi-Sunyer, N. : At the XIX International Physiological Congress, Montreal, 1073
Piaggio, Prof. H. T. H. : Foundations of Analysis, *review*, 7
Introduction to Modern Prime Number Theory, *review*, 137
Einführung in die freie Geometrie ebener Kurven, *review*, 269
General Network Analysis, *review*, 325
Algebraic Projective Geometry, *review*, 741
Pickard, Miss P. M. : Froebel's Influence on English Education, *review*, 219
Pickford, Dr. M. : Anticholinesterases, 843
Pickford, Dr. R. W. : A Pedigree for Three Types of Colour-Vision Defect, 1010
Pickles, Dr. V. R. (Harris, Prof. G. W., and) : Reflex Stimulation of the Neurohypophysis (Posterior Pituitary Gland) and the Nature of Posterior Pituitary Hormone(s), 1049
Pickthorn, Dr. K. W. M. : Education in Science, 1029
Picture Conservation : Synthetic Materials in (Arthur Lucas and Norman Bromelle), 752
Pienaar, E. : Appointed superintendent of agriculture, Tanganyika, 753
Pierach, A. : Biological Rhythms, 944

Pieroni, P F, and others Non-Identity of Intermedin and Adrenocorticotrophic Hormone, 547
Pig : Proprioceptive Fibres in the Ocular Muscles of the (F. Kane and Mary E Law), 1049
Pig Food Aureomycin and Penicillin in (Agricultural Research Council, Report No. 13), 382
Pigeons (Homing) · Aeroplane Observations of (Donald Griffin), 192
Pigs (New-born) · Hæmolytic Disease of, caused by Iso-Immunization of Pregnancy (J. C Buxton and N. H. Brooksbank), 355
Pilgrim, A. F., and others Conversion of Plant Nitrogen to Microbial Nitrogen in the Rumen of the Sheep, 347
Piltdown Implements · Chemical Examination of the (Dr. K. P. Oakley and Dr. J. S. Weiner), 1110
Piltdown Man (Dr. J. S Weiner, Dr K. P. Oakley and Prof. W. E. Le Gros Clark), 981
Pinus radiata (D. Don) . Heartwood Formation in (J. Maddern Harris), 552
Pippard, Dr. A. B. Superconductivity, 896
Pitt, Frances A Sanctuary Planted, *review*, 325
  Puffins, *review*, 375
  Obituary of the Duke of Bedford, 749
  Finding Nests, *review*, 828
Pitt-Rivers, Rosalind Mechanism of Formation of the Thyroid Hormone, 1074
Pituitary Body of Chordates Origin of the (David B. Carlisle), 1098
Pitzer, Prof. K. S, and others Nomenclature of *cyclo*Hexane Bonds, 1096
Piveteau, Prof. Jean (publié sous la direction de) Traité de paléontologie, Tome I, Les stades inférieurs d'organisation du règne animal, Tome 2, Problèmes d'adaptation et de phylogenèse, *review* by R. V. Melville, 560
Piwowarsky, Prof. E. *Death* of, 938
Planck (Max) Association for the Advancement of Science, 334
Plane Sets of Points · Elements of the Topology of (Prof. M. H. A Newman), second edition, *review* by Dr. R. G. Cooke, 325
Plane Stress Problems A Resistance-Network Analogue Method for solving (G. Liebmann), 78
Planned Management of Forests (N. V. Brasnett), *review* by Prof. H. M. Steven, 370
Plant Agglutinins : Some Interrelationships of the Erythrocytes of various Species with (Lieut.-Colonel G. W. G. Bird), 401
Plant Biophysics at Leeds, 231
Plant Disease · Genetical Aspects of (British Mycological Society Conference on), 989
  Resistance to a, associated with High Glucose Content of Leaf (L. C. Hughes and H. D Fowler), 316
Plant Diseases (Dr. F. T Brooks), second edition, *review* by Dr. S. G Jones, 368
Plant Enzyme Extract · Synthesis of Sucrose by a (J. F. Turner), 1149
Plant Growth · Soil Physical Conditions and (compiled by the Joint Committee on Soil Tilth, American Society of Agronomy, American Society of Agricultural Engineers, edited by Byron T. Shaw), *review* by Dr. H. L Penman, 48
Plant Growth Substances (Prof. L. J. Audus), *review* by Prof. R. L. Wain, 1117
  Chemistry of (Prof R. L. Wain), 710
Plant Growth-Regulating Activity · Chemical Structure in relation to (Symposium at the University of Lund), 710
Plant Growth-Regulating Substances, *review* by Prof. R. L. Wain, 1117
Plant Material A New Method for the Quantitative Determination of Chloride in (S. Samson), 1042
  Preservation of the Virus of Tomato Spotted Wilt in Dried (Dr. Rupert J. Best and H. P. C. Gallus), 315
Plant Nitrogen : Conversion of, to Microbial Nitrogen in the Rumen of the Sheep (F. V Gray, A. F. Pilgrim and R. A. Weller), 347
Plant Pathology Genetics and (Prof. K Mather), 989
Plant Pathology at the Imperial College of Science and Technology, 838
Plant Seeds · Hæmagglutinin Anti-N in (F. Ottensooser and K Silberschmidt), 914
Plant Surfaces Distribution of Copper Fungicide Deposits on (Dr. J. T Martin), 313
Plant Tissue Measurement of Colonization and Survival of Soil *Fusaria* in Detached (Dr. R. H. Stover), 465
Plants · Mineral Nutrition of, *review* by Prof. W Stiles, 422
  Nitrogen in the Life of (Dr Dimitrii Prianischnikov), translated by S A Wilde, *review* by Prof A C. Chibnall, 513
  Role of Nitrogen in, *review* by Prof. A. C Chibnall, 513
Plants (Garden) The Genetics of (M. B. Crane and W J C. Lawrence), fourth edition, *review* by Prof S. C Harland, 7
Plants (Green) Vanadium as an Essential Element for (Prof. Daniel I. Arnon and Gunilla Wessel), 1039
Plants (Guar and Cucurbit) : Ozonium Wilt of, in Bihar (J. N. Mishra), 209
Plants (Higher) Lignin Chemistry and the Taxonomy of (G. H. N. Towers and Prof. R Darnley Gibbs), 25
  Zymasis and Acid Metabolism in (Dr. S. L. Ranson), 252
Plants (Perennial) Field Experimentation with Fruit Trees and other (S. C. Pearce), *review* by H D. Patterson, 221
Plants (Tobacco) · Some Effects of Mosaic Virus on Nitrogen and Phosphorus Metabolism in (Dr. Rupert J. West and H. P. C. Gallus), 347
Plants (Vascular) : Comparative Observations on the Shoot Apices of (Prof. C. W. Wardlaw), 1172
  Spores and Tracheids of, from the Vindhyan System, India—the Advent of Vascular Plants (Dr. K. Jacob, Mrs. Chinna Jacob and R. N. Shrivastava), 166
Plants of the Bible (Dr. Harold Nr Moldenke and Alma L Moldenke), *review* by Dr. H. R. Fletcher, 1162
Plants of the Florissant Beds, Colorado Fossil (Harry D MacGinitie), 1090
Plasmagenes · Role of, *review* by Prof. C. H. Waddington, 784
Plasmodium in Common Indian Partridges (A P. Ray, V. N. Bhatnagar and M. K. Menon), 687
Plasmodium knowlesi . Isolation of a New Strain of (Colonel Jaswant Singh, A. P. Ray and C. P. Nair), 122
Plastic Deformation of Metals (Conference at the University of Bristol), 572
Plastic Sulphur (J. Schenk and Prof J A. Prins), 957
Plasticity (Brown University, Providence, R I, the Engineering Mechanics Division of the American Society of Civil Engineers, and the Office of Naval Research Symposium on), 17
Plastics Industry Education Fund Scholarships at the Borough Polytechnic, 18
Plastics and Allied Industries Postgraduate Research Scholarships in the Textile, (Courtaulds' Scientific and Educational Trust Fund Awards) 383
Platinum Medal for 1954 of the Institute of Metals awarded to Dr. Lesli Aitchison, 1173
Platinum Metals (A. R. Powell), 700
Platinum Metals Exhibition of the Institution of Metallurgists to be opene by the Duke of Edinburgh, 384
Platt, Prof B. S., and Fox, Dr. R. H. . Provisioning of Expeditions in th Field, 974
Platt, Prof. Robert : Appointed a member of the Medical Research Council 485
Pledge, Dr. H. T · Library Co-operation in Great Britain, 60
Pleistocene Correlation and Nomenclature (Appointment of a Committee on, by the International Association on Quaternary Research), 942
Pleistocene Marine Beds : Correlation of Pliocene and (D. F. W. Baden-Powell), 762
Plenderleith, Dr. H. J., and Organ, R M. : Preservation of Museum Objects 441
Pliocene and Pleistocene Marine Beds · Correlation of (D. F. W. Baden-Powell), 762
Podzolized Soils Sesquioxide Immobilization and Clay Movement in (Dr. C. Bloomfield), 958
Pohl, Prof. R. · Honorary membership of the American Association o Physics Teachers conferred on, 339
Points Elements of the Topology of Plane Sets of (Prof. M. H A. Newman), second edition, *review* by Dr R. G. Cooke, 325
Poirault, A. P. At the fourth meeting of the European Association o Exploration Geophysicists, 190
Poisons (Mitotic) . Carbon Dioxide Fixation and (Dr. S. Aronoff and G. E Graf), 1043
Polak, E. Jan · At the fourth meeting of the European Association of Exploration Geophysicists, 190
Polani, Dr. Paul Group Discussion, 800
Polar Gases near the Critical Point : Restricted Rotation in (Frank E. Harris and Berni J. Alder), 774
Polarization (Galvanic) : Effect of, on the Impulse Discharge from the Horizontal Ampulla of the Isolated Elasmobranch Labyrinth (Prof. Otto Lowenstein), 549
Polarized Light (Plane) · Motor Responses evoked by the Dorsal Ocelli of *Sarcophaga aldrichi* Parker, and the Orientation of the Fly to (Dr. W. G. Wellington), 1177
Polarographic Determination of Calcium : An Indirect (Dr. B. Breyer and J McPhillips), 257
Polarographic Effect of Carbon Dioxide in Solutions of Ethyl Alcohol (Dr. A. A. Vlček), 861
Pole and Equator of the Sun : Difference of Temperature between (Dr A. K. Das and K. D. Abhyankar), 496
Polinard, Prof E · Biochemical Problems of Lipids, 573
Polish Mathematical Congress, 1033
Polish Mathematicians · Congress of, 1033
Polished Mineral Surfaces . Electron Microscope Photographs of (J. Kenyon), 114

  Intranuclear, of the Oocytes in *Artemia salina* L. (N. Fautrez-Firlefyn and Prof. J. Fautrez), 163
  Origin of the Absorption Band at 1,500 cm.$^{-1}$ in (H. Lenormant and E. R. Blout), 770
Proteins (Grass Pollen) : Precipitins to (Dr. Rosa Augustin), 307
Prothoracic Glands : Activity of the Incretory Centres of *Locustana pardalina* during Embryogenesis—Function of the (Dr. Bryn M. Jones), 551
Prothrombin (Purified) : Identification of Amino-Acids present in, by Circular Paper Chromatography (Gauganga Ray, N. C. Ganguli and S. C. Roy), 809
Proton Acceptor Properties of Deeply Coloured *Cyclopentadiene* Polymers (B. Elder and Dr. A. Wassermann), 73
Proton Synchrotron of the University of Birmingham, 704
Protons (1-MeV.) : Formation of Hydrogen Peroxide in Water by (Dr. R. J. Shalek and Prof. T. W. Bonner), 259
Protozoa : Hæmoglobin in (Prof. D. Keilin and Dr. J. F. Ryley), 451, *erratum*, 526
Protozoologists, Society of : To Publish the *Journal of Protozoology*, 984
Protozoology, *review* by Prof. Otto Lowenstein, 323
Protozoology, Journal of (Society of Protozoologists), 984
Provisioning of Expeditions in the Field (Nutrition Society and the Royal Geographical Society Symposium on), 974
Prowse, Dr. W. A. : Ionization Phenomena in Gases, 798
Prowse, Dr. W. A., and Lane, P. E. : Breakdown of a Gas subject to Crossed Electric Fields, 116
Prozenttabellen organischer Verbindungen, C—H—O, C—H—N, C—H—O—N, C—H, C—H—S, C—H—O—S, C—H—N—S, C—H—O—N—S (Dr. H. Gysel), *review* by Prof. J. W. Cook, 48
Pryor, A. W. : Recent Developments in Ultrasonics and Optics, 443
Przibram, Prof. K. : Colour Bands in Fluorspar, 860
Pseudomonas fluorescens : A Cytochrome Peroxidase from (Howard M. Lenhoff and Dr. Nathan O. Kaplan), 730
Pseudomonas syringae : Control of, with Streptomycin (D. W. Dye), 683
Pseudotuberculosis among Stock-Doves in Hampshire (Dr. P. A. Clapham), 353
Psychiatry, and the Biochemistry and Pharmacology of the Nervous System Research in (Grant of £28,000 from the Rockefeller Foundation of New York to the Department of Experimental Psychiatry of the University of Birmingham for), 145
Psychiatry of Twins, *review* by Dr. Clifford Allen, 739
Psychical Research   Statistical Significance in (G. Spencer Brown), 154, 594 ; (Dr. S. G. Soal, Prof. F. J. M. Stratton and Dr. R. H. Thouless), 594
Psychoanalytical School : A Truant from the, *review* by Dr. Clifford Allen, 827
Psychological Problems in the Recognition of Excellence (Prof. D. W. Harding), 435
Psychology (American) : History of (A. A. Roback), *review* by Prof. John Cohen, 599
Psychology of Business Decision-making under Uncertainty : Logic, Philosophy and (British Association for the Advancement of Science, Section F (Economics), Symposium on), 701
Psychology of Personality, *review* by Prof. John Cohen, 698
Psychology and Psychotherapy of Otto Rank (Dr. Fay B. Karpf), *review* by Dr. Clifford Allen, 827
Psychotherapy of Otto Rank : The Psychology and (Dr. Fay B. Karpf), *review* by Dr. Clifford Allen, 827
Psychotic and Neurotic Illness in Twins (Eliot Slater, with the assistance of James Shields), *review* by Dr. Clifford Allen, 739
Pterophyllum in the Parsora Beds, South Rewa, India : Occurrence of (K. M. Lele), 1195
Public : Museums and the (Museums Association Conference on), 106
  Relations with the (Acton Society Trust, Nationalized Industry Series 12), 151
Public Accounts, Committee of : Third Report for the Session 1952–53, 555
Public Analysts and other Analytical Chemists, Society of : To publish *Analytical Abstracts*, 984
Public Analysts and other Analytical Chemists, Society of, and others : Report of the Joint Committee on Infra-red Spectra, 795
Public Analysts and other Analytical Chemists, Society of (Biological Methods Group), and others : Symposium on Organo-Phosphorus Insecticides, 944
Puccinia polysora Underw. : Resistance to the Maize Rust (W. R. Stanton and R. H. Cammack), 505
Puffins (R. M. Lockley), *review* by Frances Pitt, 375
Pugh, Dr. L. G. C. E. : Provisioning of Expeditions in the Field, 974
Pugh, Dr. W. J. : Geological Survey Boring in Great Britain, 12
Pulling, M. J. L., and others : Technical Arrangements for the Sound and Television Broadcasts of the Coronation Ceremonies on 2nd June, 1953, 1129
Pulmonary Tumours and Vestigial Tail in the House Mouse : Linkage between (Dr. W. E. Heston), 1007
Pulsford, M. F.   Possible *P-Q* Type Variation in Infectious Laryngotracheitis Virus, 1193
Punnett, Dr. Thomas, and Fabryl, Dr. Akinyele : Production of Oxygen from Chloroplast Preparations—Photochemical Oxygen Production from Isolated Algal Chloroplast Fragments, 947
Purcell, Prof. E. M. : Nuclear Magnetism (Eleventh Richtmyer Memorial Lecture of the American Association of Physics Teachers), 338
Purchon, Prof. R. Denison : Library Classification of Zoology Books, 940
Puri, Dr. B. R. (Lakhanpal, M. L., and) : Boiling Point of Capillary-condensed Water, 917
Purification of Secretin by Freezing Out of Impurities from Methanolic Solution at −80° C. (J. E. Jorpes and V. Mutt), 124
Purines in Grassland Herbage (W. S. Ferguson and R. A. Terry), 346
Purines for Nucleic Acid Synthesis in Man : Utilization of (Dr. Leonard Hamilton), 457
Pteridosperms : Evolution of the Ovule in (Prof. John Walton), 436
Ptychoderidæ (British) : Records of (Dr. C. Burdon-Jones), 342 ; Occurrence of the Enteropneust *Glossobalanus sarniensis* Koehler in North Ireland (C. Edwards), 343
Purple : Human Visual (Dr. F. Crescitelli and Dr. H. J. A. Dartnall), 195
Purple (Visual) : Effect of Lenophore Hormone on Regeneration of, in Solution (Prof. Toshimasa Hanaoka), 866
Purpose of a University, 131
Pursey, H. : Thermal Anomaly in the Elastic Constants of Chromium, 864
Pyridine : Action of Thionyl Chloride on Carboxylic Acids in the presence of (J. A. Cade and Dr. W. Gerrard), 29
Pyrimidines : A New Synthesis of (Dr. G. Shaw and Mrs. G. Sugowdz), 955
Pyrophosphate : Effect of, on the Shortening of Muscle-Fibre Models in presence of Adenosine Triphosphate (J. R. Bendall), 586
Pythium Parasites of Sitka Spruce Seedlings (J. H. Warcup), 280

QUALITATIVE Organic Micro-analysis based on Physical Constants—Identification of Amino-Acids (Dr. A. Lacourt, G. Sommereyns, C. Francotte and N. Delande), 906
Quality and Quantity of Protein for Man and Livestock (Dr. D. P. Cuthbertson), 434
Quantitative Aspects of the Function of the Sympathico-Adrenal System (Olov Celander), 812
Quantitative Aspects of the Indirect Action of X-Radiation at various Concentrations on *E. coli* (C. Biagini), 868
Quantitative Determination of Chloride in Plant Material : A New Method for the (S. Samson), 1042
Quantity of Protein for Man and Livestock : Quality and (Dr. D. P. Cuthbertson), 434
Quartz Clocks of the Greenwich Time Service (H. M. Smith), 984
Quastel, Prof. J. H. : Elected a Fellow of the Royal Society of Canada, 1176
Quaternary Research, International Association on : Appointment of a Committee on Pleistocene Correlation and Nomenclature, 942
Queen Mary College, London : Retirement of Prof. H. R. Robinson from the chair of physics, 100
  Appointment of Dr. G. O. Jones to the chair of physics, 100
  Title of professor emeritus of physics in the University of London conferred on Prof. H. R. Robinson, 234
Queen's University, Belfast : Appointment of Dr. W. M. Gibson and Dr. E. B. Armstrong as lecturers in physics, 60
  Appointment of D. M. McDowell as a lecturer in civil engineering (hydraulics), 60
  Appointment of Dr. H. G. Heal as lecturer in chemistry, 1173
  Appointment of J. G. Stuart as lecturer in soil mechanics, 1173
  Appointment of Dr. J. Lowy as lecturer in experimental zoology, 1173
Quenouille, M. H. : The Design and Analysis of Experiment, *review*, 785
Quickfit and Quartz, Ltd. : Glassware for the Laboratory, 754
Quine, Prof. Willard van Orman : Methods of Logic, *review* by F. I. G. Rawlins, 884
l-Quinic Acid from the Peach Fruit : Isolation of (E. F. L. J. Anet and T. M. Reynolds), 1188

RABBIT : Inhibition of Superovulation in the (C. E. Adams), 82
Rabbit (Australian Wild) : Changes in the Mortality-rate due to Myxomatosis in the (Prof. Frank Fenner), 228
Rabbit Blood : Isolation of Thorium B (Lead)-binding Substance from the Erythrocytes of (Dr. K. K. Reddi), 202
'Rabbit-Gait' in the House Mouse (S. A. Mallyon), 312
Rabbit Ova (Unfertilized) : Storage of—Subsequent Fertilization and the Probability of Normal Development (Dr. M. C. Chang), 353
Rabbits : Myxomatosis in (Laboratory Animals Bureau of the Medical Research Council Memorandum on), 1085
Race Crossing in Man (J. C. Trevor), *review* by Dr. H. Gruneberg, 137
Racemic Mixtures : Separation of, by Electrophoresis in a Strong Centrifugal or Magnetic Field (Prof. Frederick C. Landrum), 499
Rachitogenic Factor in Green-feeds : Carotene, a (A. B. Grant), 627
Radar : Radio Techniques for, *review* by Dr. R. A. Smith, 602
Radar Research Establishment, Malvern : Amalgamation of the Telecommunications Research Establishment and the Radar Research and Development Establishment, 277
  Appointment of W. J. Richards as director, 277
Radar-Sonde Meteorological Station at Crawley (Mullard, Ltd.), 440
Radar Technique : Radio and (Dr. A. T. Starr), *review* by Dr. R. A. Smith, 602
Radiation   Solar, a Leading Weather Element (Dr. C. G. Abbot), 1089
Radiation (Fission-Product) : Use of (Chemistry Division of the Atomic Energy Research Establishment Symposium on), 147
Radiation (Solar) : Forecasting Weather from (Dr. C. E. P. Brooks), 1089
Radiation at Radio Frequencies   Cosmic Origin of (F. Hoyle), 296
Radiation from the Spiral Nebula Messier 81 : Radio-Frequency (R. Hanbury Brown and C. Hazard), 853
Radiation from the Supergalaxy : Radio (Prof. J. D. Kraus and H. C. Ko), 538
Radiation Chemistry : The Development of Radiochemistry and (Sir John Cockcroft), 895
Radiation-produced Hydrogen Peroxide : Effects of Commercial and (Tikvah Alper), 957
Radiative Equilibrium and Neutron Diffusion : Basic Methods in Transfer Problems— (V. Kourganoff, with the collaboration of I. W. Busbridge), *review* by Prof. W. H. McCrea, 924
Radicals   Reaction of Nitric Oxide with Gaseous Hydrocarbon Free (H. T. J. Chilton and Dr. B. G. Gowenlock), 73
Radicle   Stimulation of the Growth of the, after Treatment of Tomato Seed with Bromine Water (William G. Boll), 963
Radio (Continuous-Wave) : Investigation of Travelling Disturbances in the Ionosphere by (Y. V. Somayajulu), 818 ; (B. Ramachandra Rao and E. Bhagiratha Rao), 819
Radio Astronomy (Prof. Bernard Lovell and Dr. J. A. Clegg), *review* by J. A. Ratcliffe, 47

Radio-Astronomy in the Tropics (Prof. H. E. Huntley), 108
Radio Communication : Modulation Theory in, *review* by F. Horner, 5
Radio Consultative Committee, International : Forthcoming Plenary Assembly in London, 107
Radio Duct : Ultra-short-wave Field-strength in a Ground-based (R. S. Unwin), 856
Radio Echo Observations of the Daytime Meteor Streams in 1952 (Mary Almond, K. Bullough and G. S. Hawkins), 751
Radio Engineers, British Institution of : Re-election of William E. Miller as president, 384
  Clerk Maxwell Premium for 1952 awarded to Dr. Charles Susskind, 384
  Election of Sir Noel Ashbridge as an honorary member, 797
Radio Engineers, Institute of, and others : Conference on High-Frequency Electrical Measurements, 52
Radio Frequencies : Cosmic Origin of Radiation at (F. Hoyle), 296
Radio-Frequency Radiation from the Spiral Nebula Messier 81 (R. Hanbury Brown and C. Hazard), 853
Radio-frequency Source of Extra-galactic Origin : An Extended (R. Hanbury Brown and C. Hazard), 997
Radio Instruments : Catalogue of (Marconi Instruments, Ltd.), 985
Radio Interference Suppression (G. L. Stephens), second edition, *review* by Dr. B. G. Pressey, 94
Radio Noise-Burst : Eruptive Prominence of February 26, 1953, and Associated (Dr. K. Das and K. Sethumadhavan), 446 ; Radio Observations at the Time of an Ascending Solar Prominence (R. D. Davies), 447
Radio Noise bursts from Solar *M*-Regions (Dr. A. K. Das and B. N. Bhargava), 855
Radio Observations at the Time of an Ascending Solar Prominence (R. D. Davies), 447
Radio Outburst (Solar) : Evidence of Harmonics in the Spectrum of a (J. P. Wild, J. D. Murray and W. C. Rowe), 533
Radio Propagation : Non-standard (P. G. Forsyth), 966
Radio Radiation from the Supergalaxy (Prof. J. D. Kraus and H. C. Ko), 538
Radio Source Cygnus I : Fine Structure of the Extra-terrestrial (R. C. Jennison and M. K. Das Gupta), 996, *erratum*, 1030
Radio Star : Determination of the Position of a (F. G. Smith), 241
Radio Techniques for Radar, *review* by Dr. R. A. Smith, 601
Radio Waves : The Use of (J. A. Ratcliffe), 986
Radio and Radar Technique (Dr. A. T. Starr), *review* by Dr. R. A. Smith, 602
Radioactive Colchicine : Fixation of, by Ehrlich Ascites Carcinoma Cells (A. Back and E. J. Walaszek), 202
Radioactive Cortisone and Hydrocortisone, 187
Radioactive Hydrogen Sulphide : Quantitative Paper Chromatography of Traces of Metal with the Aid of (P. C. van Erkelens), 357
Radioactive *p*-Iodophenylhydroxylamine : Studies with Erythrocytes labelled with (Dr. Harold Jackson), 80
Radioactive Isotopes in Great Britain : Standardization of (W. E. Perry), 1026
Radioactive Materials : Catalogue of (Radiochemical Centre, Amersham), 1130
  Laboratory Experiments with, *review* by R. L. Fortescue, 1163
  Techniques of Using and Handling (Courses at the Isotope School of the Atomic Energy Research Establishment), 656, 1084
Radioactive Substances : Two dimensional Paper Chromatography of (F. P. W. Winteringham), 727
Radioactivity (Body) : Determination of Total, using Liquid Scintillation Detectors (F. Reines, R. L. Schuch, C. L. Cowan, jun., F. B. Harrison, E. C. Anderson and F. N. Hayes), 521
Radioautographic Study of the Localization of Tobacco Mosaic Virus Antigen (Dr. F. Gavosto and Mrs. A. Ficq), 406
Radiocarbon (Natural) : Use of an Acetylene-filled Counter for (Dr. A. R. Crathorn), 632
Radiocarbon Dating—Large-scale Preparation of Acetylene from Organic Material (Dr. H. Barker), 631
Radiochemical Centre, Amersham : Catalogue of Radioactive Materials, 1130
Radiochemical Practice : Modern (Dr. G. B. Cook and Dr. J. F. Duncan), *review* by G. R. Martin, 267
Radiochemistry : Techniques of, *review* by G. R. Martin, 267
Radiochemistry and Radiation Chemistry : The Development of (Sir John Cockcroft), 895
Radioiodine (^{131}I) by the Thyroid : Effect of Diuresis on Uptake of (Dr. J. Pahaut, Dr. J. Govaerts and Dr. P. Bonhomme), 545
Radioisotope Conference (Atomic Energy Research Establishment), 986
Radiosensitivity at Different Levels of Biological Complexity (Dr. A. Glucksmann), 442
Radiostrontium in Monkeys : Toxicity of (G. M. Edington, J. M. Judd and Dr. A. H. Ward), 122
Radley, J. A. : Starch and its Derivatives, third edition revised, Vol. 1, *review* by Prof. E. L. Hirst, 972
Radoslovich, E. W. : Advances in Methods of Studying Clays, 288
Rae, F. W. : Arctic Meteorology, 1167
Raikes, Dr. H. R. : Higher Technological Education, 270
Rain : Reduction in Light accompanying Exceptionally Heavy (Dr. W. R. G. Atkins and Pamela G. Jenkins), 79
Rain Forest : The Tropical, an Ecological Study (Prof. P. W. Richards), *review* by Dr. W. B. Turrill, 177
Raindrop Spectrometer : Photoelectric (B. J. Mason and R. Ramanadham), 1176
Rainey, Dr. R. C., and Sayer, H. J. : Some Recent Developments in the Use of Aircraft against Flying Locust Swarms, 224
Raitio, Aune, and others : *Listeria* Infection in the Guinea Pig caused by Feeding with Aureomycin, 767
Rajasthan Academy of Sciences : Election of Officers for 1953–54, 613
Rajputana Desert : Symposium on the, 58
Ram Spermatozoa : Dark-Ground Illumination of (H. M. Dott), 626
Ramachandra Rao, B., and Bhagiratha Rao, E. : Investigation of Travelling Disturbances in the Ionosphere by Continuous-Wave Radio, 819
Ramana Murthy, Bh. V. (Ramanathan, Dr. K. R., and) : Daily Variation of Amount of Ozone in the Atmosphere, 633
Ramanadham, R. (Mason, B. J., and) : Photoelectric Raindrop Spectrometer, 1176
Ramanathan, Dr. K. R. : Commemoration of the sixtieth birthday of, 1130
Ramanathan, Dr. K. R., and Ramana Murthy, Bh. V. : Daily Variation of Amount of Ozone in the Atmosphere, 633
Ramnarayan Chellaram College of Commerce : Construction of the, 441
Ramsay, Dr. J. A. : A Physiological Approach to the Lower Animals, *review* by Dr. J. A. Kitching, 92
Ramsey, J. M. : Appointed a senior assistant conservator of forests, Gold Coast, 234
Ramsay Memorial Fellowships for research in Chemistry : Awards, 103
Ramsey, N. W. : Effect of Temperature on the Conductivity induced in Insulators by X-Rays, 214
Rana pipiens Tadpoles : Regular Occurrence of the Haploid Number of Chromosomes in Mesenchymal Cells of the Tail Tip of (Dr. Elizabeth Ufford Green), 766
Ranatra elongata : Sex Chromosomes of (Dr. M. D. L. Srivastava and C. C. Das), 505
Randall, J. B. : Appointed director of veterinary services and animal husbandry, Uganda, 60
Randhawa, M. S. : Beautifying India, *review*, 49
Random Choice in the Chemotherapy of Tuberculosis, *review* by Dr. Vincent C. Barry, 322
Ranganathan, B. (Subramaniam, Dr. M. K., and) : Are *Torulae* Haploid ?, 628
Rank, Prof. D. H. : High-Frequency Electrical Measurements, 52
Rank, Otto : The Psychology and Psychotherapy of (Dr. Fay B. Karpf), *review* by Dr. Clifford Allen, 827
Rankin, J. J. : First Record of the Rare Beaked Whale, *Mesoplodon europaeus*, Gervais, from the West Indies, 873
Ransom Fellowship of the Pharmaceutical Society awarded to Keith Henry Palmer, 280
Ranson, Dr. S. L. : Zymasis and Acid Metabolism in Higher Plants, 252
Rao, B. Ramachandra, and Rao, E. Bhagiratha : Investigation of Travelling Disturbances in the Ionosphere by Continuous-Wave Radio, 819
Rao, E. Bhagiratha (Rao, B. Ramachandra, and) : Investigation of Travelling Disturbances in the Ionosphere by Continuous-Wave Radio, 819
Rao, K. Pampapathi, and others : Rate of Activity as a Function of Intertidal Height within Populations of some Littoral Molluscs, 1108
Raper, C. R. : Appointed agricultural officer, Federation of Malaya, 753
Raper, Dr. K. B., and others : Nidulin and 'Ustin', Two Chlorine-containing Metabolic Products of *Aspergillus nidulans*, 344
Rapid Staining of Intestinal Amoebae on Wet Mounts (C. P. Nair), 1051
Rat : Changes in the Vascular and Lipoid Pattern of the Adrenal Cortex of the, following Hypophysectomy (J. D. Lever, Dr. D. B. Cater and M. P. Stack-Dunne), 33
  Effect of 2,2-*bis*(Parachlorophenyl)-1,1-Dichloroethane (DDD) on the Adrenal Cortex of the (H. B. Stoner), 1044
Rat Behaviour (Association for the Study of Animal Behaviour Symposium on), 488
Rat Liver : Intracellular Distribution of Vitamin A Esterase Activity in (Dr. J. Ganguly and Prof. H. J. Deuel, jun.), 120
Rat Thymocytes : Effect of Ultra-violet Light on Deoxyribonucleic Acid in (S. J. de Courcy, jun., J. O. Ely and M. H. Ross), 119
Rat's Stomach : Autoradiographic Detection of Sulphur-35 Synthesis by the Mucous Neck Cells of the (Prof. Leonard F. Bélanger), 1150
Ratcliffe, J. A. : Outline of Radio Astronomy, *review*, 47
  The Use of Radio Waves, 986
Rate of Flow of Polycrystalline Ice (J. W. Glen), 721
Rations for Britain's Livestock : Problems in providing (Scottish Group of the Nutrition Society Conference on), 844
Rats : Aspects of Vitamin A Deficiency in (J. S. Lowe, Prof. R. A. Morton and Prof. R. G. Harrison), 716
Rats (Hyperthyroid) : An Unidentified Growth-Factor for Yeast and (Dr. E. Tria and Dr. O. Barnabei), 203
Rats under Normal and Post-Irradiation Conditions : Urinary Excretion of Acid and Neutral Deoxyribonuclease by (O. D. Kowlessar, Prof. K. I. Altman and L. H. Hempelmann), 867
Rats and Mice on the Farm (Ministry of Agriculture and Fisheries, Bulletin No. 30), eighth edition, 335
Rauwolscine : Effect of, on the Action of Adrenaline on Blood Pressure (J. N. Mukherjee), 867
Raveau, Camille : *Death* of, 15
Ravin, Dr. A. W. : Adaptation in Micro-organisms, 235
Raw Materials : World Production of (Royal Institute of International Affairs), new revised edition, 442
Rawer, Dr. Karl : Die Ionosphäre, *review* by C. M. Minnis, 514
Rawlins, F. I. G. : George Berkeley, 1685–1753, 326
  Methods of Logic, *review*, 884
  Many-valued Logics, *review*, 928
  Introduction to the Foundations of Mathematics, *review*, 1020
Ray, A. P., and others : Isolation of a New Strain of *Plasmodium knowlesi*, 122
  A Plasmodium in Common Indian Partridges, 687
Ray, D. L. : Digestion of Wood by *Limnoria lignorum*, 830
Ray, Gauranga, and others : Identification of Amino-Acids present in Purified Prothrombin by Circular Paper Chromatography, 809
Raymont, T. : *Death* of, 439 ; *obituary* by A. E. Dean, 480
Rayons : Small-Angle X-Ray Scattering and Interparticle Interference in (Prof. A. N. J. Heyn), 1000
Reaction : The Fries (Abdel Fattah Marey, Dr. Fawzy G. Baddar and William I. Awad), 1186
  The ^{54}Fe(n,p)^{54}Mn (G. H. Stafford and L. H. Stein), 1103
Reaction (Ninhydrin) : Influence of Cations on the, for the Determination of Amino-Acids (Dr. Hanan Meyer and Emanuel Riklis), 543
Reaction of Nitric Oxide with Gaseous Hydrocarbon Free Radicals (H. T. J. Chilton and Dr. B. G. Gowenlock), 73
Reactions of Cytochrome c : Complex (Prof. H. Lundegårdh), 303
Reactivity : Chromatographic Separation, using Chemically Treated Paper, of Aldehydes and Ketones on the Basis of their (Dr. A. G. Newcombe and Dr. S. G. Reid), 455
Reactivity of Iodine Pentoxide towards Carbon Monoxide : Influence of some Impurities, notably Potassium, upon the (E. G. Adams and N. T. Simmons), 1104
Read, Prof. John : Science in Education, 101
  Kindly Fruits, *review*, 264
  Obituary of Prof. H. E. Fierz-David, 523
  Awarded the David Anderson-Berry Prize for 1953 of the Royal Society of Edinburgh, 1085
  Fluorine in the Human Skeleton, 1156
Reagent : A Chromatographic Colour, for a Group of Amino-Acids (Dr. G. Curzon and J. Giltrow), 356

Reagent for Keto-Sugars: New Specific (R. Johanson), 956
Reasbeck, Dr. P.: Appointed I.C.I. Fellow in physics at the University of Birmingham, 1084
Reasbeck, Dr. P., and others: Cosmic-Ray Production of Helium in Meteorites and their Ages, 1168
  Production by Cosmic Rays of Helium-3 in Meteorites, 200
Reason: The Counter-Revolution of Science, Studies on the Abuse of (Prof. F. A. Hayek), 367
Reavell, B. N.: Chemical Processes and Chemical Engineering Techniques, 711
Receptor-destroying Enzyme: Turbidity-reducing Activity of Influenza Virus and, on Sheep Submandibular Mucoid (Dr. J. F. McCrea), 912, 1173
Recherche Scientifique, Centre National de la: Conference on the Study of Molecules of Water in Solids, 188
Recherche Scientifique dans l'Industrie et l'Agriculture, Institut pour l'Encouragement de la: Rapport Annuel, Exercice 1952, 387
Reclamation of Deserts, 894
Recognition of Excellence: Psychological Problems in the (Prof. D. W. Harding), 435
Recombination without Sexual Reproduction in *Penicillium chrysogenum* (Dr. G. Pontecorvo and G. Sermonti), 126
Recombination Coefficient in the *F*-Regions—a Possible New Process of Ionization of Nitrogen Molecules (R. B. Banerji), 953
Reconstituted Collagen: A Soluble Form of (D. S. Jackson and J. Bell), 1046
Reconstitution of Virus X-saturated Potato Varieties with Malachite Green (Dr. D. Norris), 816
Recorded Sound, Ltd., British Institute of, in conjunction with the Department of Extra Mural Studies of the University of London: Lecture-recitals of sound-recordings in the study of Music, Drama, Literature and Science, 526
Recording of Optical Transients by Photo-multipliers: Detection and (Dr. R. F. Saxe), 1198
Recording Photoelectric Spectrophotometer at Kodaikanal Observatory (A. K. Das, R. Ananthakrishnan and B. N. Bhargava), 383
Recovery of Isotopic Boron and Lithium from Nuclear Research Emulsions (M. L. Smith), 1054
Recovery of the Sahara (R. St. Barbe Baker), 894
Recruitment of American Scientists, *review* by Sir Arthur Trueman, 373
Recruitment for the Civil Service, 990
Recruitment of Higher Personnel for the British Textile Industry, 707
Red Cells: Agglutination of, by *Cl. welchii* (E. N. Dafaalla and Dr. M. A. Soltys), 38
Red Cells (Human): Rates of Glycolysis in, in relation to Energy Requirements for Cation Transport (Ralph E. Bernstein), 911
Red Halophilic Bacterium: Aspartate–Glutamate Transaminase in a (J. Robinson and H. Katznelson), 672
Reddi, Dr. K. K.: Isolation of Thorium B (Lead)-binding Substance from the Erythrocytes of Rabbit Blood, 202
Reducing Substances in *Zostera* (E. J. Ferguson Wood), 916
Reduction in Light accompanying Exceptionally Heavy Rain (Dr. W. R. G. Atkins and Pamela G. Jenkins), 79
Reduction of Liquid Flow in Paper Electrophoresis (M. A. Jermyn and R. Thomas), 728
Reed, J. R.: Electrical Insulation, 10
Rees, W. R., and others: *D*-Enzyme, a Disproportionating Enzyme in Potato Juice, 153
Reflex Stimulation of the Neurohypophysis (Posterior Pituitary Gland) and the Nature of Posterior Pituitary Hormone(s) (Prof. G. W. Harris and Dr. V. R. Pickles), 1049
Refraction Experiments: Seismic, in the Indian Ocean and in the Mediterranean Sea (Dr. T. F. Gaskell and J. C. Swallow), 535
Refrigeration, International Institute of: Joint meeting at Zurich of Commissions I and II, 708
Regeneration of Root-Cuttings: Factors affecting the (J. P. Hudson), 411
  Seasonal Variation in the (J. Dore), 1189
Regeneration of Visual Purple in Solution: Effect of Melanophore Hormone on (Prof. Toshimasa Hanaoka), 866
Regional Farming in Britain: History of, 985
Regional History (Association of Agriculture and the British Agricultural History Society Conference on), 985
Registrar General: Statistical Review of England and Wales for the Two Years 1948–49, Text, Medical, 1135
  Statistical Review of England and Wales for the Year 1951, Tables, Part 1, Medical, 1135
Regulating System Design: Servomechanisms and (Harold Chestnut and Robert M. Mayer), Vol. 1, *review* by Prof. J. Greig, 91
Reid, R. D.: Genetical Aspects of Plant Disease, 990
Reid, Dr. S. G. (Newcombe, Dr. A. G., and): Chromatographic Separation, using Chemically Treated Paper, of Aldehydes and Ketones on the Basis of their Reactivity, 455
Reimann, H.: Biological Rhythms, 943
Rein, Prof. F. H.: *Obituary* by Prof. D. H. Smyth, 381
Reines, F., and others: Determination of Total Body Radioactivity using Liquid Scintillation Detectors, 521
Reinhardt, Prof. Wm. O.: Experimental Production of Hepatic Necrosis and Fibrosis with Water, 915
Relation of the Permittivity of Biological Cell Suspensions to Fractional Cell Volume (Dr. Hugo Fricke), 731
Relations with the Public (Acton Society Trust, Nationalized Industry Series 12), 151
Relationship between Dominance, Phenotypic Stability and Variability, and a Theory of Alternative Genetic Pathways (Dr. D. Lewis), 1136
Relativistic Treatment of Rigid Motion (T. Mitra), 858
Relativity (Special): Equations of Motion for Continuous Matter of, in the Lagrange Variables (S. F. B. Tyabji), 1147
Relaxation Processes: Dielectric, in Ethanol (F. X. Hassion and Prof. R. H. Cole), 212
Relaxing Factor of Muscle: 'Adenosine Triphosphate–Creatine Transphosphorylase' as (Dr. L. Lorand), 1181
Relaxing Factors in Muscle (M. C. Goodall and Dr. Andrew G. Szent-Gyorgyi), 84
Relf, E. F.: Awarded the Gold Medal of the Royal Aeronautical Society, 381
  Obituary of Prof. L. Prandtl, 836
Religion: Some Aspects of the Conflict between Science and (Prof. H. H. Price), 709
Religion and Science: Relation of (Very Rev. W. R. Matthews), 376
Remane, A.: Biological Rhythms, 943
Remanent Magnetism of Varved Clays from Sweden (D. H. Griffiths), 539
Rennison, B. D.: Appointed zoologist, East African Tsetse and Trypanosomiasis Research and Reclamation Organization, East Africa High Commission, 1030
Renold, Sir Charles: Training for Management, 693
Renton, C. A.: Superconductivity, 896
Renton, J. E. F.: Chemical Processes and Chemical Engineering Techniques, 711
Repressed Monetary Inflation: Open and (Prof. F. W. Paish), 433
Reproducibility of Differential Centrifugation Experiments in Tissue Fractionation (Prof. C. de Duve and J. Berthet), 1142
Reproduction (Sexual): Recombination without, in *Penicillium chrysogenum* (Dr. G. Pontecorvo and G. Sermonti), 126
Reproduction in Aphids: Flight Muscle Autolysis and (Bruce Johnson), 813
Research: Aeronautical, in Academic Institutions, 569
  Agricultural, 1953 (Lord Rothschild), 273
  Biogeographical, at High Altitudes—Journey to the Gughé Highlands (Southern Ethiopia), 1948–49— (Dr. Hugh Scott), 388
  Forest, in India and Burma, 1948–49, 233
  Medical, in the United States (K. M. Endicott and E. M. Allen), 1172
  Nuclear, in Sweden (Government of Sweden Grants for), 145
  Oil Pollution—Plotting of Currents in the North Atlantic (National Institute of Oceanography), 750
Research (Aeronautics): Documentation in, 941
Research (Arctic or Sub-Arctic): Fellowship and Scholarships for (McGill University and the Arctic Institute of North America), 1085
Research (Cancer): Progress of, 788
Research (Fisheries): Hydrography in, *review* by David Vaux, 179
Research (Industrial and Technological): American Aid for, in Britain, 15
Research (Marine): National Sovereignty, the Continental Shelf and, 1063
Research (Nuclear): An International Laboratory for (D. W. Fry), 646
Research (Psychical): Statistical Significance in (G. Spencer Brown), 154, 594; (Dr. S. G. Soal, Prof. F. J. M. Stratton and Dr. R. H. Thouless), 594
Research (Recent): Stonehenge in the Light of (R. J. C. Atkinson), 474
Research (Scientific): Industrial Efficiency and, 877
  Organizations engaged in, on an International Scale in the Pacific (Pacific Science Association), 1131
Research (Scientific and Industrial): American Aid for, in Great Britain, 528
Research at the Wellcome Foundation, 654
Research at the Zoological Station, Naples: Gabriella Zuccari Scholarship for (University of Padua), 146
Research in Chemistry: Grants for (Chemical Society), 336
Research in Electron Optics: Recent (Physical Society Symposium on), 61
Research in Industry, 1029
Research in Industry: Empirical (Acton Society Trust and the York Civic Trust Discussion on), 897
Research on Kilns in Japan, 752
Research in Psychiatry, and the Biochemistry and Pharmacology of the Nervous System (Grant of £28,000 from the Rockefeller Foundation of New York to the Department of Experimental Psychiatry of the University of Birmingham for), 145
Research in the Social Sciences: Register of, 1091
Research Appointments (Royal Society), 185
Research Development in the Machine-Tool Industry of the U.S.S.R. (W. G. Cass), 64
Research Emulsions (Nuclear): Recovery of Isotopic Boron and Lithium from (M. L. Smith), 1054
Research Essay Competition, 940
Research Fellowship: Glaxo Laboratories (Granted through the Friends of the Hebrew University to Miss Alisa Tietz), 187
  Nuffield Gerontological (Nuffield Foundation), 654
Research Fellowship in Aeronautics: English Electric (Awarded to R. G. Anderson), 280
Research Fellowship in Gerontology: Nuffield Professorial (Nuffield Foundation), 654
Research Fellowship in Metallurgy (Established by the United Steel Companies, Ltd., in the University of Sheffield), 753
Research Fellowships: Leverhulme (Awards for 1953), 17
  Wellcome Pharmaceutical (Awards), 280
Research Fellowships in the United States for Young European Scientific Workers, 569
Research Grants: Fellowship Awards and (National Science Foundation), 102
Research Grants for 1953: Completion of (National Science Foundation), 613
Research Scholarship of the Pharmaceutical Society awarded to Kenneth Albert Kerridge, 280
Research Scholarships: Postgraduate, in Textile Technology (Courtaulds' Scientific and Educational Trust Fund Awards), 383
  Postgraduate, in the Textile, Plastics and Allied Industries (Courtaulds' Scientific and Educational Trust Fund Awards), 383
Research Studentship in Chemistry founded by the Polymer Corporation, Ltd., Sarnia, Ontario, in the University College of North Staffordshire, for the support of postgraduate research on cationic polymerization, 709
Research Studentships in Chemistry (British Celanese, Ltd., Awards), 442
Research Studentships in Ecology (Nature Conservancy Awards), 708
Research Tool: Differential Thermobalance, a New (Prof. W. L. De Keyser), 364
Research and Development (Scientific): Federal Funds for, at Non-profit Institutions 1950–51 and 1951–52 (National Science Foundation, Federal Funds for Science, 1), 575
  Federal Funds for, for the Fiscal Years 1952 and 1953 (National Science Foundation, Federal Funds for Science, 2), 1171
Research and Development in British Colonial Territories, 1034
Research and Teaching in Animal Husbandry: William McIlrath Fellowship for (Commonwealth Scientific and Industrial Research Organization), 794
Resistance: Electrical Contact, between Magnetically Attracted Bodies (C. W. Wilman), 917

Resistance to Drugs: Origins of (United States Office of Naval Research and the University of Pennsylvania Symposium on), 754
Resistance to the Maize Rust, *Puccinia polysora* Underw. (W. R. Stanton and R. H. Cammack), 505
Resistance to a Plant Disease associated with High Glucose Content of Leaf (L. C. Hughes and H. D. Fowler), 316
Resistance-Network Analogue Method for solving Plane Stress Problems (G. Liebmann), 78
Resistant Components of the Cortex of Animal Hair (E. H. Mercer), 164
Resistant Houseflies bred on a Medium containing Benzene Hexachloride: Amount of Gamma-Benzene Hexachloride picked up by (F. R. Bradbury, P. Nield and J. F. Newman), 1052
Resistant Membranes from Wool and Hair Fibres (B. Manogue and M. S. Moss), 806
Resonance Spectrograms (Nuclear Magnetic): A Rapid Method of obtaining (K. Taylor), 722
Respiratory and Digestive Anatomy of a Microhylid Tadpole, *Hypopachus aguae* Stuart (R. Maxwell Savage), 354
Respiratory Chain: Mechanism of Phosphorylation in the (Dr. E. C. Slater), 975
Responsibilities: The Scientist's (Dr. R. L. M. Synge), 62
Responsibilities of Universities and their Faculties: The Rights and (Association of American Universities), 217, 598, 641
Responsibility for Atomic Energy: Parliamentary, 1083
Responsibility and Freedom: Professional and Academic, 597
Restricted Rotation in Polar Gases near the Critical Point (Frank E. Harris and Berni J. Alder), 774
Revelle, Roger (Munk, Walter, and): On the Geophysical Interpretation of Irregularities in the Rotation of the Earth, 707
Reversal of the Antibacterial Activity of Polymyxin by Divalent Cations (B. A. Newton), 160
Reversal of the Heart-beat in Tunicates (C. A. Haywood and Prof. H. P. Moon), 40; (Dr R. H. Millar), 41
Reverse Thermo-remanent Magnetism of Igneous Rocks: Origin of (Prof. T. Nagata, S. Akimoto and S. Uyeda), 630
Reversible Mutations: Theory of (Dr. D. Lewis and Leslie K. Crowe), 501
'Rex' Mutant in the Cat (A. C. Jude), 81
Rey, Jean: The Essays of (a facsimile reprint of the original edition of 1630, with an Introduction by Dr. Douglas McKie), *review* by V. A. Eyles, 1118
Reynolds, Dr. Doris L.: Basic Magma chilled against Acid Magma, 69
Reynolds, Dr. S. R. M.: A Source of Amniotic Fluid in the Lamb—the Naso-Pharyngeal and Buccal Cavities, 307
Reynolds, T. M. (Anet, E. F. L. J., and): Isolation of *l*-Quinic Acid from the Peach Fruit, 1188
Reynoldson, Dr. T. B.: Awarded a Leverhulme Research Grant for 1953, 17
Rheological Curve (A. de Waele and Mrs G. L. Lewis), 298
Rheology: Second International Congress on (Dr. G. W. Scott Blair), 487
Rheology, British Society of: Symposium on the Mixing of Thick Liquids, Pastes and Slurries, 384, 846
  Election of Officers, 709
Rhesus Monkey with B Agglutinogen in the Erythrocytes (E. C. Büchi), 873
Rhinanthus minor Ehrh.: Prochromosomes and Supernumerary Chromosomes in (David J. Hambler), 629
Rhizobium trifolii: Influence of Rhizosphere Micro-organisms on the Virulence of (J. R. Harris), 507
Rhizomorph Formation in *Armillaria mellea* (S. D. Garrett), 796
Rhizosphere Micro-organisms: Influence of, on the Virulence of *Rhizobium trifolii* (J. R. Harris), 507
Rhodanese in Cardiac Muscle: Intracellular Distribution of (Jennifer M. Moyle), 508
Rhodophyceae: Acetocarmine as a Nuclear Stain in (C. S. Prakasa Rao), 1197
Riabouchinsky, Prof. D.: La définition des nombres par leur valeur numérique et par leur origine—role de ce concept en philosophie mathématique, 752
Riboflavine and Thiamine Contents of Saffron, *Crocus sativus* Linn. (Prof. J. V. Bhat and Rajul Broker), 544
Rice Institute, Houston, Texas: Appointment of Dr. Carey Croneis as provost and Harry Carothers Weiss professor of geology, 103
Rice Moth Larva (*Corcyra cephalonica* St.): Tryptophane Metabolism in (T. K. Sundaram and P. S. Sarma), 627
Ricerche, Consiglio Nazionale delle, and others: Conference on Optics and Micro-waves, 102
Richard, H.: At the fourth meeting of the European Association of Exploration Geophysicists, 190
Richards, Dr. A. N.: Pharmacology of Renal Tubular Mechanisms, 1075
Richards, Dr. O. W.: Appointed to the University of London chair of zoology and applied entomology at the Imperial College of Science and Technology, 895, 1027; work of, 1027
Richards, Prof. P. W.: The Tropical Rain Forest, an Ecological Study, *review* by Dr. W. B. Turrill, 177
  Tenth International Phytogeographical Excursion, 566
Richards, T. C.: European Association of Exploration Geophysicists—Paris Meeting, 189
Richards, W. J.: Appointed director of the Radar Research Establishment, Malvern, 277; work of, 277
Richardson, Dr. E. G.: Sounds of Jets, 54
  Musical Acoustics, 189
  Engineering Aspects of Acoustics, *review*, 645
Richardson, Dr. L. F.: *Death of*, 750; *obituary* by Prof. P. A. Sheppard, 1127
Richter, C. P.: Biological Rhythms, 943
Richter, H. R.: Biological Rhythms, 944
Richtmyer Memorial Lecture of the American Association of Physics Teachers (Prof. E. M. Purcell), 338
Riddell Memorial Lectures, Twenty-fifth Series (Prof. C. A. Coulson), 376
Riddlestone, H. G.: Electrical Insulation, 10
Rideal, Sir Eric: Dyeing and Tanning, 1031
Rideal, Sir Eric, and others (edited by): Advances in Catalysis and related Subjects, Vols. 3 and 4, *review* by Dr. James Bell, 516
Rights and Responsibilities of Universities and their Faculties (Association of American Universities), 217, 598, 641
Rigid Motion: A Relativistic Treatment of (T. Macral), 858
Rih-ching, Hong (Makino, Katashi, and): Substances in Bone-Marrow Extract accelerating Coagulation of the Blood, 205
Riklis, Emanuel (Meyer, Dr. Hanan, and): Influence of Cations on the Ninhydrin Reaction for the Determination of Amino-Acids, 543
Riley, Dr. D. P.: Colloid Science (edited by H. R. Kruyt), Vol. I, Irreversible Systems, *review*, 741
Riley, Dr. D. P., and Arndt, Dr. U. W.: X-Ray Scattering Evidence regarding the Protein–Nucleic Acid Combination in Nucleoproteins, 294
Riley, Dr. D. P. (Arndt, Dr. U. W., and): Intra-Helix S—S Linked Structures for Insulin, 245
  Structure of Air-dry Sodium Thymonucleate, 803
Rimington, C., and others: Porphobilinogen as a Porphyrin Precursor, and Interconversion of Porphyrins, in a Tissue System, 292
Rintoul, Leonora Jeffrey (Baxter, Evelyn V., and): The Birds of Scotland, Vols. 1 and 2, *review* by Seton Gordon, 971
Rishworth, D. E. H.: Appointed geologist, Federation of Malaya, 1085
Ritchie, Sir Douglas: Oil Pollution of the Sea, 1026
Ritchie, J. C.: Awarded a Senior Studentship for 1953 by the Royal Commission for the Exhibition of 1851, 17
Ritchie, J. N.: Preventive Medicine among Farm Livestock, 561
River Floods in Great Britain, 263
Roach, Arvid E., and others: Score Resistance of Bearing Metals, 301

Seed-borne Disease by *Chaetomium cochliodes* Pall. : Control of a, under Natural Conditions (M. Tvelt), 39
Seedlings (Tree) Growth Response of, to Mycorrhizal Mycelia in the Absence of a Mycorrhizal Association (Dr. Ida Levisohn), 316
Seeds, Dr. W E., and others Helical Structure of Crystalline Deoxypentose Nucleic Acid, 759
Seeds of *Cannabis sativa* L. Action of Gamma-Rays on (J. Moutschen and Dr. J. Govaerts), 350
Seeing through the Atmosphere, *review* by Dr. John W. T. Walsh, 1118
Seelis, K. H. · At the fourth meeting of the European Association of Exploration Geophysicists, 190
Seely, Prof. Samuel (LePage, Prof. Wilbur R , and) : General Network Analysis, *review* by Prof. H. T. H. Piaggio, 325
Segal, Earl, and others : Rate of Activity as a Function of Intertidal Height within Populations of some Littoral Molluscs, 1108
Seismic Refraction Experiments in the Indian Ocean and in the Mediterranean Sea (Dr. T. F. Gaskell and J. C. Swallow), 535
Seitz, Prof. F. : Impurity Phenomena, 385
Selby, M. F. H. : Appointed a chief agricultural officer, Nyasaland, 60
Select Committee on Estimates Eighth Report from the, together with the Minutes of Evidence taken before Sub-Committee E and Appendices, Session 1952–1953, Schools, 467
Selective Method for the Staining of Negri Bodies in Histological Brain Sections (Dr. I. Zlotnik), 962
Selem, A. M. : At the fourth meeting of the European Association of Exploration Geophysicists, 191
Selenium Tetrafluoride · Structure of (H J. M. Bowen), 171 ; (F. Lachman), 499
Self, Sir Henry London Town, 476
Self-Reversal of Thermo-remanent Magnetization of Igneous Rocks (Prof. Takesi Nagata), 850
Selman, G. G., and Counce, S. J. : Abnormal Embryonic Development in *Drosophila* induced by Ultrasonic Treatment, 503
Semen (Mammalian) . Glycerophosphoryl Choline as a Precursor of Free Choline in (Dr. Frank Lundquist), 587
Semple, Prof. J G., and Kneebone, G T. Algebraic Projective Geometry, *review* by Prof. H. T. H. Piaggio, 741
Sen (H. K.) Memorial Lecture of the Institution of Chemists (India), (Dr. S. Husain Zaheer), 797
Sen, G. P. (Nandi, Dr. P., and) . An Antifungal Substance from a Strain of *B. subtilis*, 871
Sen Gupta, Dr. J. C : Elected president of the Botanical Society of Bengal, 142
Senter, General W. O. High-level Forecasting, 1167
Separation of the Methyl Esters of the C_{12}–C_{22} Fatty Acids by Vapour-Phase Chromatography · Analytical (F. R. Cropper and A. Heywood), 1101
Separation of Organic Compounds : A New Method of (R. C Vasisth and Dr. M. S. Muthana), 862
Separation of Racemic Mixtures by Electrophoresis in a Strong Centrifugal or Magnetic Field (Prof. Frederick C. Landrum), 499
Sequential Sampling in Biological Assay (Elisabeth Bukovics and F. X. Wohlzogen), 1058
Serby, J E. : Appointed director-general of guided weapons to the Ministry of Supply, 1131
Serial Correlations · Errors in the Estimation of (J. A. Pope and Dr. F. H. Marriott), 778
Series, Dr. G. W. Recent Developments in Ultrasonics and Optics, 443
Sermonti, G. (Pontecorvo, Dr. G , and) Recombination without Sexual Reproduction in *Penicillium chrysogenum*, 126

Serotonin and other Tryptamines : A Fluorescence Test for (Dr. John B. Jepson and B. J. Stevens), 772
Serpentine Minerals (J. Zussman), 126
Serum : Susceptibility of the Guinea Pig to Pharmacological Factors from its own (Dr. M. E. Mackay, Dr. A. A. Miles, Dr. M. S. Schachter and Dr. D. L. Wilhelm), 714
Service, H. : Appointed director of the Geological Survey, Federation of Malaya, 60
Servomechanisms and Regulating System Design (Harold Chestnut and Robert W. Mayer), Vol. I, *review* by Prof. J. Greig, 91
Sesquioxide Immobilization and Clay Movement in Podzolized Soils (Dr. C. Bloomfield), 958
Sethumadhavan, K. (Das, Dr. R. K., and) : Eruptive Prominence of February 26, 1953, and Associated Radio Noise-Burst, 446
Settling of Dispersions of Carbon in Organic Media : Stability and (Prof. F. H. Garner, M. F. Mohtadi and Dr. C. W. Nutt), 259
Severiens, J. C. : Impurity Phenomena, 387
Sewell, G. W. F. : Awarded a Nature Conservancy Research Studentship in Botany, 708
Sex Chromosomes of *Ranatra elongata* (Dr. M. D. L. Srivastava and C. C. Das), 505
Sex Hormones and Cancer, *review* by Prof. W. S. Bullough, 1066
Sex-limited Effects : Chromosomal Inversions with (Dr. A. Brito da Cunha), 815
Sex-Ratio, a Non-Mendelian Character in *Drosophila bifasciata* (Prof. G. E. Magni), 81
Sexual Reproduction : Recombination without, in *Penicillium chrysogenum* (Dr. G. Pontecorvo and G. Sermonti), 126
Shackle, Prof. G. L. S. : The Logic, Philosophy and Psychology of Business Decision-making under Uncertainty, 703
Shalek, Dr. R. J., and Bonner, Prof. T. W. : Formation of Hydrogen Peroxide in Water by 1-MeV. Protons, 259
Shand, Prof. S. James : Rocks for Chemists, *review* by C. O. Harvey, 137
Shapiro, Prof. Harry L. : *Obituary* of Dr. Wendell C. Bennett, 936

Sharp, Gillian, and others : Cortisone and the Metabolic Response to Injury, 158
Shaw, Dr. B., and others: The B-Vitamins in Wheat—the Unique Aleurone Layer, 993
Shaw, Byron T. (edited by) : Soil Physical Conditions and Plant Growth (compiled by the Joint Committee on Soil Tilth, American Society of Agronomy, American Society of Agricultural Engineers), *review* by Dr. H. L. Penman, 48
Shaw, Dr. G., and Sugowdz, Mrs. G. : A New Synthesis of Pyrimidines, 955
Sheep : Conversion of Plant Nitrogen to Microbial Nitrogen in the Rumen of the (F. V. Gray, A. F. Pilgrim and R. A. Weller), 347
  Influence of Inorganic Sulphate on the Copper-Molybdenum Interrelationship in (A. T. Dick), 637
Sheep Skin : Use of Cyanol in the Study of Blood-vessels in (M. L. Ryder), 125
Sheep Submandibular Mucoid : Turbidity-reducing Activity of Influenza Virus and Receptor-destroying Enzyme on (Dr. J. F. McCrea), 912, 1173
Sheffield, F. W., and others : A Host-Protein Component of Influenza Viruses, 669
Sheffield Organization for the Interchange of Technical Publications : Twentieth Annual Meeting, 382
Shell Petroleum Co., Ltd. : Venture in Education, 483
  Postgraduate Scholarship Awards, 485
Shell Spectrum of ζ Tauri : Spectrophotometric Comparison of the (Anne B. Underhill), 279
Shepherd, Dr. D. M., and others : Detection of 5-Hydroxytryptamine by Paper Chromatography, 357
  Chromaffin Bodies of various Species of Dogfish, 509
Sheppard, Prof. P. A. : *Obituary* of Dr. L. F. Richardson, 1127
  Meteorological Conference at Toronto, 1166
Sheridan, Dr. J., and others : Microwave Spectrum of Penta-1 . 3-diyne, 771
Sherman, J. K. (Bunge, Dr. R. G., and) : Fertilizing Capacity of Frozen Human Spermatozoa, 767
Shields, James (Slater, Eliot, with the assistance of) : Psychotic and Neurotic Illness in Twins, *review* by Dr. Clifford Allen, 739
Shiff, Clive, and others : Frequency of Moulting in Anura, 408
Shilo, M., and others : Promotion of Infection by Intravenously Administered Polysaccharides, 765
Shipworm Infestation *in vivo* : Use of X-Ray Spectroscopy for examining (Dr. D. J. Crisp, Dr. L. W. G. Jones and Dr. W. Watson), 408
Shivas, M. (Manton, Prof. I., and) : Two Cytological Forms of *Polypodium virginianum* in Eastern North America, 410
Shock Waves : Hydrodynamical Theory of Detonation and, *review* by Prof. D. M. Newitt, 699
Shock Waves (Weak) : Generation of (Dr. V. Timbrell), 540
Shockley, Dr. W. : Presented with the first O. E. Buckley Solid-State Physics Prize of the American Physical Society, 338
Shoot Apices of Vascular Plants : Comparative Observations on the (Prof. C. W. Wardlaw), 1172
Shooter, Dr. R. A. : Appointed to the University of London readership in bacteriology at St. Bartholomew's Hospital Medical College, 60
  Chemotherapy of Man and Animals, *review*, 644
Short, Philip : Use of Non-geometrical Perspective in the Two-dimensional Representation of Solid Objects, 1002
Shortening of Muscle-Fibre Models in presence of Adenosine Triphosphate : Effect of Pyrophosphate on the (J. R. Bendall), 586
Shrivastava, R. N., and others : Spores and Tracheids of Vascular Plants from the Vindhyan System, India—the Advent of Vascular Plants, 166
Shrubs : A New Agricultural Research Institute—Glasshouse Crops, Mushrooms and Outdoor Flowers and (Dr. E. E. Cheesman), 140
Shrubsall, E. J. : Appointed director of forests, Federation of Malaya, 571
Sibert, Prof. Harold W. : High-Speed Aerodynamics, *review*, 600
Sickle-cell Haemoglobins in Human Anaemias : Detection of Foetal and (Dr. G. H. Beaven and Dr. J. C. White), 1006
Sickle Cell Trait in Seventy-two Australian Aboriginals : Absence of the (W. R. Horsfall and Dr. H. Lehmann), 638
Siday, R. E. : Recent Research in Electron Optics, 62
Side-Chains : Contribution of, to the Infra-Red Spectra of Proteins—the 6·5-μ Band (Dr. Gert Ehrlich and Prof. G. B. B. M. Sutherland), 671
Sidebands and Transients in Communication Engineering : Harmonics, (C. Louis Cuccia), *review* by F. Horner, 5
Siegbahn, Prof. K. M. G. : Elected an Honorary Fellow of the Royal Society of Edinburgh, 57
Sieveking, G. de G. : Appointed curator, Department of Museums, Federation of Malaya, 60
Silberschmidt, K. (Ottensooser, F., and) : Haemagglutinin Anti-*N* in Plant Seeds, 914
Silent World : The (J. Y. Cousteau, with Frédéric Dumas), *review* by Dr. A. J. Brook, 370
Silica Gel : An Unknown Acid from Brain-Extracts Chromatographed on (F. Friedberg, L. M. Marshall and L. H. Newman), 1191
Siliceous Spicules in the Calcareous Sponge, *Leucandra johnstonii* (Carter), (N. B. Eales), 687
Silicone Rubber and other Substances : Toxicity Studies on (Dr. John D. B. MacDougall), 124
Silkworm : Action of Irradiated Cytoplasm on Untreated Chromosomes of the (Prof. Yoshio Nakao), 625
Silkworm, *Bombyx mori* L. : Effect of Antibiotics on the Growth of the (M. R. Venkatachala Murthy and M. Sreenivasaya), 684
Sillars, Dr. R. W. : Electrical Insulation, 9
Sillén, Prof. Lars Gunnar, and others : Problems in Physical Chemistry, *review* by Dr. J. C. Speakman, 93
Silver Benzoate–Halogen Complexes : Phenylation, Benzoyloxylation and Halogenation of Aromatic Compounds by (Dr. D. Bryce-Smith), 863
Silver Jubilee Commemoration Award of the Illuminating Engineering Society awarded to J. R. Wakefield and to Miss P. M. Excell, 709
Silver Medal of the Royal Aeronautical Society awarded to H. Grinsted, 381
Simms Gold Medal of the Royal Aeronautical Society awarded to Major P. L. Teed, 381
Simey, Prof. T. S. : Sir Edwin Chadwick, the Social Reformer, *review*, 421
Simmonds, Dr. David H. : Leucine–Isoleucine Content of Wool, 677
Simmons, N. T. (Adams, E. G., and) : Influence of some Impurities, notably Potassium, upon the Reactivity of Iodine Pentoxide towards Carbon Monoxide, 1104

Stansfield, H. : Museums and the Public, 107
Stansfield, R. G. : Empirical Research in Industry, 897
Stanton, W. R., and Cammack, R. H. : Resistance to the Maize Rust, *Puccinia polysora* Underw., 505
Stanton, W. R., and Sinclair, W. K. : Mutagenic Possibilities of Phosphorus-32, 484
Star : The Outer Layers of a (Prof. R. v. d. R. Woolley and D. W. N. Stibbs), *review* by Prof. W. H. McCrea, 924
Star (Radio) : Determination of the Position of a (F. G. Smith), 241
Starch : Chemistry of, *review* by Prof. E. L. Hirst, 972
Starch and its Derivatives (J. A. Radley), third edition revised, Vol. 1, *review* by Prof. E. L. Hirst, 972
Stark, K. H. : Electrical Insulation, 9
Starr, Dr. A. T. : Radio and Radar Technique, *review* by Dr. R. A. Smith, 602
State and Agriculture (Sir James Scott Watson), 942
State University of Florida : Research Studies No. 9, 1131
Statistical Astronomy (Robert J. Trumpler and Harold F. Weaver), *review* by Prof. W. M. Smart, 1017
Statistical Method in Biological Assay (Dr. D. J. Finney), *review* by Dr. J. O. Irwin, 925
Statistical Review of England and Wales for the Two Years 1948–49 (Registrar General), Text, Medical, 1135
Statistical Review of England and Wales for the Year 1951 (Registrar General), Tables, Part 1, Medical, 1135
Statistical Significance in Psychical Research (G. Spencer Brown), 154, 594 ; (Dr. S. G. Soal, Prof. F. J. M. Stratton and Dr. R. H. Thouless), 594
Statistical Study of the Stellar System, *review* by Prof. W. M. Smart, 1017
Statistical Year-Book of the World Power Conference, 1948–1950 (edited by Frederick Brown), *review*, 473
Statistics : Fine Particles and, *review* by P. G. W. Hawksley, 1017
  Post-doctoral Fellowships in (University of Chicago), 613
  Small Particle (Dr. G. Herdan), *review* by P. G. W. Hawksley, 1017
Staub, A. : At the XIX International Physiological Congress, Montreal, 1073
Staudinger, Prof. Herman : Awarded the Nobel Prize for Chemistry for 1953, 893 ; work of, 893
Stauropteris with two Megaspores (K. R. Surange), 233
Stead, B. D. : Awarded a postgraduate research scholarship by Courtaulds' Scientific and Educational Trust Fund, 383
Stead, Prof. Gilbert : Title of professor emeritus of physics in the University of London conferred on, 234
Stebbing, Prof. E. P. : Timber Progress and Desk Book for 1953, *review*, 374
  Forests, Catchment Areas and Water Supplies throughout the World, 524
  Federal Forest Administration in Malaya—Annual Report for 1951, 1090
  Forests of the Belgian Congo, 1177
Stedman, Dr. E. : Anticholinesterases, 842
Steel Structures : Welded (Ministry of Works, the Institution of Civil Engineers and the Institution of Structural Engineers Conference on), 485
Steers, Prof. J. A. : Penck's "Morphological Analysis", *review*, 1163
Steeves, Dr. Taylor A. (Sussex, Dr. I. M., and) : Growth of Excised Fern Leaves in Sterile Culture, 624
Stehle, Philip : Medium-Energy Nuclear Physics—Conference at the University of Pittsburgh, 527
Stein, Dr. Gabriel, and others : Factors modifying the Influence of Light on Germination, 452
Stein, L. H. (Stafford, G. H., and) : The $^{54}\text{Fe}(n,p)^{54}\text{Mn}$ Reaction, 1103
Stellar System : A Statistical Study of the, *review* by Prof. W. M. Smart, 1017
Stem Borer of Oats : Action of Insecticides on a—the Frit Fly (P. T. Walker), 916
Stephen, M. J. : Awarded a Postgraduate Scholarship by the Shell Petroleum Co., Ltd., 485
Stephens, G. L. : Radio Interference Suppression, second edition, *review* by Dr. B. G. Pressey, 94
Stephens, R. : Awarded a postgraduate research scholarship by Courtaulds' Scientific and Educational Trust Fund, 383
Sterile Culture : Growth of Excised Fern Leaves in (Dr. I. M. Sussex and Dr. Taylor A. Steeves), 624
Sterility : Prize for an Essay on Infertility and (American Society for the Study of Sterility), 656
Sterility in *Theobroma cacao* L. (R. Knight and H. H. Rogers), 164
Sterilization of Timber with Methyl Bromide (J. B. Cartwright, D. W. Edwards and M. J. McMullen), 552
Steroid (Adrenal) : A New, 1116
Stetten, De Witt : Metabolic Influence of Insulin, 1073
Steven, Prof. H. M. : Forest Management, *review*, 370
Stevens, B. J. (Jepson, Dr. John B., and) : A Fluorescence Test for Serotonin and other Tryptamines, 772
Stevens, Dr. K. W. H. : Appointed reader in theoretical physics at the University of Nottingham, 103
Steward, E. G., and Runciman, W. A. : Alkaline Earth Uranates of the R_3MX_6 Type, 75
Steward, F. C., and Caplin, S. M. : Coconut Milk Growth Factor, 102
Steward, F. C., and Muhlethaler, K. : Cell-Walls of *Valonia* and *Dictyosphaeria*, 708
Stewart, Dr. C. P., and Guthrie, Dr. Douglas (edited by) : Lind's Treatise on Scurvy, a Bicentenary Volume containing a reprint of the first edition of A Treatise of the Scurvy by James Lind, with additional Notes, 50

Streptomyces albidoflavus: Inhibition of *Fusarium culmorum* by (F. A. Skinner), 1191
Streptomycin: Control of *Pseudomonas syringae* with (D. W. Dye), 683
Streptomycins: Paper Electrophoresis of (M. C. Foster and G. C. Ashton), 958
Stress Problems (Plane): A Resistance-Network Analogue Method for solving (G. Liebmann), 78
Stretch Receptors in the Stomach: Impulses in Vagal Afferent Fibres from, and their Role in the Peripheral Mechanism of Hunger (Dr. A. S. Paintal), 1194
Streuli, C. A.: Impurity Phenomena, 386
Striations in Discharges: Origin of (Dr. G. D. Morgan), 542
Strickland, E. H.: Elected a Fellow of the Royal Society of Canada, 1176
Striga: Relation of Witchweed, to Fertility in Tropical Soils (K. Wilson Jones), 128
Strock, Dr. L.: Impurity Phenomena, 386
Structural Basis of the Cross-Striations in Muscle (Dr. Jean Hanson and Dr. Hugh E. Huxley), 530
Structural Engineers, Institution of, and others (Joint Committee): Conference on Welded Steel Structures, 485
Structure of Adenylic Acids *a* and *b* (D. M. Brown, G. D. Fasman, D. I. Magrath, Prof. A. R. Todd, W. Cochran and M. M. Woolfson), 1184
Structure of Air-dry Sodium Thymonucleate (Dr. U. W. Arndt and Dr. D. P. Riley), 803
Structure of the Atomic Nucleus (Conference at the University of Birmingham), 486
Structure of Bacitracin A (Dr. J. Porath), 871
Structure for Cellulose Triacetate: Unit Cell and Preliminary (W. J. Dulmage), 1053
Structure of Crystalline Deoxypentose Nucleic Acid: Helical (Dr. M. H. F. Wilkins, Dr. W. E. Seeds, Dr. A. R. Stokes and Dr. H. R. Wilson), 759
Structure of the Extra-terrestrial Radio Source Cygnus I: Fine (R. C. Jennison and M. K. Das Gupta), 996, *erratum*, 1030
Structure of Insulin (Dr. Conmar Robinson), 773
Structure of Insulin as indicated by Atomic Models (Dr. Conmar Robinson), 27
Structure of Ion-exchanged Forms of Chabazite (I. R. Beattie), 999
Structure of Meta-aminophenol (M. N. Dutt), 498
Structure of Poly-D-glutamic Acid isolated from Capsulated Strains of *B. anthracis* (Prof. V. Bruckner, J. Kovács and G. Dénes), 508
Structure in Polyethylene Terephthalate Fibres: Fine (A. Cobbold, R. de P. Daubeny, K. Deutsch and P. Markey), 806
Structure of Porphobilinogen (Dr. G. H. Cookson), 457
Structure of Porphyrilic Acid (Prof. Holger Erdtman and Carl-Axel Wachtmeister), 724
Structure of Selenium Tetrafluoride (H. J. M. Bowen), 171; (F. Lachman), 499
Structure of Wool (Dr. F. Happey, T. P. MacRae and G. J. Weston), 673
Structure and Texture of Catalysts (Société de Chimie Physique Conference on), 986
Structure-Activity Correlation in the Making, *review* by Prof. F. Bergel, 136
Structure Factor of Thin Tin Films from Superconductivity Measurements: Determination of the (Prof. A. Van Itterbeek, L. De Greve, L. Van Gerven and J. Schepers), 952
Strugnell, E. J.: Appointed deputy director of forestry, Federation of Malaya, 1030
Struktur des freien Molekuls (Prof. H. A. Stuart), *review* by Prof. C. A. Coulson, 423
Struthers, J. D.: Impurity Phenomena, 386
Struve, Prof. O.: Elected an Honorary Fellow of the Royal Society of Edinburgh, 57
Stuart, Prof. H. A.: Die Struktur des freien Molekuls, *review* by Prof. C. A. Coulson, 423
Stuart, J. G.: Appointed lecturer in soil mechanics at Queen's University, Belfast, 1173
Stuart, T. A.: Water Currents through Permeable Gravels and their Significance to Spawning Salmonids, etc., 407
Student (Honours): Organic Chemistry for the, *review* by Dr. J. D. Loudon, 135
Students: Movement of Postgraduate Science, 712
Studentship in Chemistry: Research (Founded by the Polymer Corporation, Ltd., Sarnia, Ontario, in the University College of North Staffordshire, for the support of postgraduate research on cationic polymerization), 709
Studentships: Senior (Royal Commission for the Exhibition of 1851 Awards), 17
Studentships in Chemistry: Research (British Celanese, Ltd., Awards), 442
Studentships in Ecology: Research (Nature Conservancy Awards), 708
Study of Animal Behaviour, Association for the: Symposium on Rat Behaviour, 488
Study and Travel in the United States: Fellowships for (Commonwealth Fund), 611
Sturrock, P. A.: Recent Research in Electron Optics, 62
Sub-Arctic Research: Fellowship and Scholarships for Arctic or (McGill University and the Arctic Institute of North America), 1085
Sub-chromatid Breakage: Chromosome Breakage Experiments with Endosperm—(L. F. La Cour and A. Rutishauser), 501
Sub-Diploid Chromosome Variation in Man and other Mammals (Dr. Leo Sachs), 205
Subject Index of British Patent Specifications, 103
Subramaniam, Dr. M. K., and Ranganathan, B.: Are *Torulae* Haploid?, 628
Substances in Bone-Marrow Extract accelerating Coagulation of the Blood (Katashi Makino and Hong Rih-ching), 205
Suckling Reflex in the Cat (Dr. A. Mohiuddin), 688
Sucrose: Synthesis of, by a Plant Enzyme Extract (J. F. Turner), 1149
Sugar Chromatography of Urine: Salt Interference in (Dr. S. Baar and Dr. J. P. Bull), 414
Sugars: A Colorimetric Estimation of, using Benzidine (Dr. J. K. N. Jones and J. B. Pridham), 161
  Paper Electrophoresis of, at High Potential Gradients (Dr. D. Gross), 908
Sugowdz, Mrs. G. (Shaw, Dr. G., and): A New Synthesis of Pyrimidines, 955
Sulphate (Inorganic): Influence of, on the Copper–Molybdenum Interrelationship in Sheep (A. T. Dick), 637
Sulphates in African Inland Waters (T. Eden), 595; (W. A. Macfadyen), 595
Sulphonamides and Antibiotics in Man and Animals (Dr. J. Stewart Lawrence and Prof. John Francis), second edition, *review* by Dr. R. A. Shooter, 644
Sulphonic Acid Group: Mesomeric Effect of the (Dr. Hch. Zollinger), 257
Sulphonphthalein Dye: Effect of Five Strains of Fowl-Plague Virus on a (Dr. M. K. Tolba and Mrs. Josephine K. Eskarous), 961
Sulphur: Plastic (J. Schenk and Prof. J. A. Prins), 957
Sulphur-35 Synthesis: Autoradiographic Detection of, by the Mucous Neck Cells of the Rat's Stomach (Prof. Leonard F. Bélanger), 1150
Sumi, F.: At the fourth meeting of the European Association of Exploration Geophysicists, 190
Summer School of Physics (Italian Physical Society), 146
Summer School in Programme Design for Automatic Digital Computing Machines (University of Cambridge Mathematical Laboratory), 18
Summers, Dr. G. H. R.: Awarded a renewal of a Ramsay Memorial Fellowship for research in Chemistry, 103
Sumner, W. L.: Literature for an Age of Science, *review*, 49
  Science News, 25, *review*, 223
  John Henry Newman and Science, 530
  Mr. Tompkins Learns the Facts of Life, *review*, 741
Sun: Difference of Temperature between Pole and Equator of the (Dr. A. K. Das and K. D. Abhyankar), 496
Sun's Variation: Long-Range Effects of the, on the Temperature of Washington, D.C. (Dr. C. G. Abbot), 1089
Sundaram, T. K., and Sarma, P. S.: Tryptophane Metabolism in Rice Moth Larva (*Corcyra cephalonica* St.), 627
Sunday Times Essay Competition, 941
Sunspot Cycle: Geomagnetic Activity and the (Dr. R. Ananthakrishnan), 854
Sunspot Observations in Spain (E. Gullón), 383
Superconductivity (Low Temperature Group of the Physical Society Discussion on), 896
Superconductivity Measurements: Determination of the Structure Factor of Thin Tin Films from (Prof. A. Van Itterbeek, L. De Greve, L. Van Gerven and J. Schepers), 952
Supergalaxy: Radio Radiation from the (Prof. J. D. Kraus and H. C. Ko), 538
Supernumerary Chromosomes in *Rhinanthus minor* Ehrh.: Prochromosomes and (David J. Hambler), 629
Superovulation in the Rabbit: Inhibition of (C. E. Adams), 82
Supersonic Aerodynamics (Edward R. C. Miles), *review*, 600
Supply, Ministry of: Golden Jubilee of the Armament Research Establishment, 1075
  Appointment of Dr. R. Cockburn as principal director of scientific research (guided weapons and electronics), 1131
  Appointment of J. E. Serby as director-general of guided weapons, 1131
Supply and Education of Managers for British Industry, 714
Suppression: Radio Interference (G. L. Stephens), second edition, *review* by Dr. B. G. Pressey, 94
Suppression by Glycine of the Phenotypic Expression of Partially Reverted Glycineless *E. coli* Mutants: Specific (Barbara E. Wright), 308
Surange, K. R.: A *Stauropteris* with two Megaspores, 233
Surface Areas of Particulate Solids: A Method for the Determination of the Approximate (D. Payne), 261
Surface Films: Effect of, on the Evaporation of Water (W. W. Mansfield), 1101
  The Physical Chemistry of (Prof. William D. Harkins), *review* by Dr. James Bell, 828

Surfaces: Elastic Deformation and the Contact of (J. F. Archard), 918
Surfaces in Close Proximity: Interaction between (L. F. Evans), 776
Surgeons, Royal College of: Custody of Downe House, Kent, transferred from the British Association to the, 482
Survival of Soil *Fusaria* in Detached Plant Tissue: Measurement of Colonization and (Dr. R. H. Stover), 465
Survival-Rate of Anopheline Mosquitoes in Nature: A New Method of Estimating the (C. C. Draper and G. Davidson), 503
Susceptibility of the Guinea Pig to Pharmacological Factors from its own Serum (Dr. M. E. Mackay, Dr. A. A. Miles, Dr. M. Schachter and Dr. D. L. Wilhelm), 714
Sussex, Dr. I. M., and Steeves, Dr. Taylor A.: Growth of Excised Fern Leaves in Sterile Culture, 624
Susskind, Dr. Charles: Awarded the Clerk Maxwell Premium for 1952 of the British Institution of Radio Engineers, 384
Sutherland, Prof. G. B. B. M. (Ehrlich, Dr. Gert, and): Contribution of Side-Chains to the Infra-Red Spectra of Proteins—the $6\cdot5$-μ Band, 671
Sutherland, K. H.: Appointed a lecturer in mechanical engineering in the University of Sheffield, 753
Sutherland, T. M.: Awarded a Postgraduate Scholarship in Husbandry by the Department of Agriculture for Scotland, 840
Sutton, Prof. O. G.: Elected president of the Royal Meteorological Society, 17
  Education in Science, 1029
Sutton, Prof. R. M.: Presented with the Oersted Medal of the American Association of Physics Teachers, 338
Sutton, Prof. W. G.: Higher Technological Education, 271
Suzuki, Tomisaburo, and others: Earthquake Damage and the Nature of the Ground, 751
Svensson, S.: Biological Rhythms, 944
Sverdrup, Prof. H. U.: Arctic Meteorology, 1167
  Elected an honorary member of the American Meteorological Society, 1168
Swain, Dr. T., and others: Identification of Flavones by the Ultra-Violet Absorption Spectra of their Ions, 23
Swain, Dr. T. (Weurman, C., and): Chlorogenic Acid and the Enzymic Browning of Apples and Pears, 678
Swallow, J. C. (Gaskell, Dr. T. F., and): Seismic Refraction Experiments in the Indian Ocean and in the Mediterranean Sea, 535
Sweden: Nuclear Research in (Government of Sweden Grants for), 145
  Remanent Magnetism of Varved Clays from (D. H. Griffiths), 539
Swindin, Norman: George E. Davis Memorial Lecture of the Institution of Chemical Engineers, 60, 848
Swine: *Eperythrozoon parvum*, a Filterable Blood Parasite of (Earl J. Splitter), 40
Swinton, Dr. W. E.: Gateways of Science, 438
  Presidential Address to Section X (Assembly of Corresponding Societies) of the British Association for the Advancement of Science, 781
Swiss Society for Natural Sciences: 133rd Annual Meeting, 187
Sycamore, *Cryptostroma corticale*: Sooty Bark Disease of (Forestry Commission, Leaflet No. 30), 947
Sykes, A. H.: Premature Oviposition in the Hen, 1098
Sykes, Dr. C.: Elected president of the Institute of Physics, 242
Sylvester, J. D., and others: A New Phenomenon in Time Judgment, 901
Symmers, Dr. W. St. C.: Appointed to the University of London chair of morbid anatomy at Charing Cross Hospital Medical School, 103
Sympathico-Adrenal System: Quantitative Aspects of the Function of the (Olov Celander), 812
Synchrotron of the University of Birmingham: Proton, 704
Synge, Dr. R. L. M.: The Scientist's Responsibilities, 62
Synthesis (Nucleic Acid): Utilization of Purines for, in Man (Dr. Leonard Hamilton), 457
Synthesis (Sulphur-35): Autoradiographic Detection of, by the Mucous Neck Cells of the Rat's Stomach (Prof. Leonard F. Bélanger), 1150
Synthesis of Carbazoles: A New (Alfred Löffler and David Ginsburg), 820
Synthesis of Components of the Vitamin B Group by *Corynebacterium diphtheriae* (Lauri Ennes), 400
Synthesis of 2-Deoxy-D-ribose: A New (P. A. J. Gorin and Dr. J. K. N. Jones), 1051
Synthesis of Pyrimidines: A New (Dr. G. Shaw and Mrs. G. Sugowdz), 955
Synthesis of Sucrose by a Plant Enzyme Extract (J. F. Turner), 1149
Synthetic Fibres: Chemistry and Physics of (Plastics and Polymer Group of the Society of Chemical Industry Symposium on), 656
Synthetic Materials in Picture Conservation (Arthur Lucas and Norman Bromelle), 752
Synthetic Polypeptides: Infra-Red Dichroism in (Dr. A. Elliott), 359
Synthetic Products of Petroleum (edited by Dr. B. T. Brooks and Dr. A. E. Dunstan), *review* by Lieut.-Colonel S. J. M. Auld, 1065
Syrett, P. J.: Ammonia Assimilation by *Chlorella*, 984
Szent-Györgyi, Dr. Andrew G. (Goodall, M. C., and): Relaxing Factors in Muscle, 84
Szigeti, Dr. B.: Dielectrics, 564
Szilard and Chalmers Effect by Irradiation of Hexavalent Chromium in an Atomic Pile (Dr. B. Ottar), 362

Taylor, J.: Detonation in Condensed Explosives, *review* by Prof. D. M. Newitt, 699
Taylor, K.: A Rapid Method of obtaining Nuclear Magnetic Resonance Spectrograms, 722
Taylor, Prof. Norman Burke (Best, Prof. Charles Herbert, and): The Living Body, third edition, *review* by Sir Charles Lovatt Evans, 4
Taylor, Sir Thomas: *Obituary* by Norman Millott, 652
Taylor, T. G., and Moore, Dr. J. H.: Avian Medullary Bone, 504
Taylor (George) of Australia Gold Medal of the Royal Aeronautical Society awarded to Group-Captain E. A. Whitely, 381
Teaching of Mechanics in British Universities (R. H. Macmillan), 898
Teague, H.: Superconductivity, 896
Technical Arrangements for the Sound and Television Broadcasts of the Coronation Ceremonies on 2nd June, 1953 (Institution of Electrical Engineers and the Engineering Institute of Canada Discussion by radio on), 1129
Technical Development: Use of Scientific and, by Industry, 87
Technical Education (Twelfth Report from the Select Committee on Estimates, Session 1952–53), 737
  Building Accommodation for, 737
Technical Libraries in Africa South of the Sahara: Directory of Scientific and (Scientific Council for Africa South of the Sahara), 233
Technical Officers in Agricultural Departments of Colonial Territories (Secretary of State for the Colonies), 187
Technical Problems of the Expansion of Television in Britain, 337
Technical Publications, Sheffield Organization for the Interchange of: Twentieth Annual Meeting, 382
Technical World: Human Values in the (Public Lectures at the Eleventh Conference of the International Federation of University Women), 475
Technical Worker in Economic Development: The Scientific and, 281
Technicians in Great Britain: Conference on the Education of Technologists and, 1029
Techniques of Radiochemistry, *review* by G. R. Martin, 267
Techniques of Using and Handling Radioactive Materials: Courses on the (Atomic Energy Research Establishment, Harwell), 656, 1084
Technological Education in Great Britain, 333; (Lincoln Gordon), 750
Technological Research in Britain: American Aid for Industrial and, 15
Technologists and Technicians in Great Britain: Conference on the Education of, 1029
Technology or a Profession: Medicine—a (Lieut.-Colonel S. M. K. Mallick), 482
Technology and Architecture: Scholarships in Science, (Massachusetts Institute of Technology), 1030
Technology and Professional Work, 482
Teed, Major P. L.: Awarded the Simms Gold Medal of the Royal Aeronautical Society, 381
  Titanium, a Metal of Engineering Importance, 608
Telegdi, V.: Medium-Energy Nuclear Physics, 527
Telephone Cable: Trans-Atlantic, 1129
Television (F. Kerkhof and W. Werner), translated by the late J. O'Connor Howe and G. Ducloux, *review* by Dr. R. L. Smith-Rose, 471
Television: Source-Book on, *review* by Dr. R. L. Smith-Rose, 471
Television in Britain: Technical Problems of the Expansion of, 337
Television Advisory Committee: First Report of the (General Post Office), 337
Television Broadcasts of the Coronation Ceremonies on 2nd June, 1953: Technical Arrangements for the Sound and (Institution of Electrical Engineers and the Engineering Institute of Canada Discussion by radio on), 1129
Television Viewing: Eye Movements in connexion with (Dr. Mary P. Lord), 964
Temperature: Difference of, between Pole and Equator of the Sun (Dr. A. K. Das and K. D. Abhyankar), 496
  Effect of, on the Conductivity induced in Insulators by X-Rays (N. W. Ramsey), 214
Temperature (High): Acceleration of Flowering in partially Vernalized Grain of Petkus Winter Rye by subsequent Treatment at (D. J. Friend and Prof. F. G. Gregory), 667
Temperature (Transition): A New Method for Determining the, of Insect Cuticular Waxes (P. J. Judge), 405
Temperature of Washington, D.C.: Long-Range Effects of the Sun's Variation on the (Dr. C. G. Abbot), 1089

Temperature Conditions : Hatching the Contents of Cysts of *Heterodera rostochiensis* with Alternating (Daphne D. Bishop), 1108
Temperature-Control in Distillation : Early Record of (Dr. F. Sherwood Taylor and Dr. C. H. Josten), 920
Temperature Phenomenon in Polymerization · *Cis-Trans* Isomerization and the Ceiling (Prof. F. S. Dainton and G. M. Bristow), 804
Temperature and Humidity Gradients in the First 100 m. over South-East England (A. C. Best, E. Knighting, R. H. Pedlow and K. Stormonth), 193
Temperatures (Low) : Crystal Structure and Magnetic Properties of Cobalt Ferrite at (H. P. Rooksby and B. T. M. Willis), 1054
Temperatures (Mesomorphic and Polymorphic Transition) · A Heating Instrument for the Accurate Determination of (Dr. G. W. Gray), 1137
Template Hypotheses · Nucleic Acid (Prof. Alexander L. Dounce), 541 ; (Dr. T. S. Work and Dr. P. N. Campbell), 541
Temple, Prof. G. : *Obituary* of Prof. R. von Mises, 333
  Stability and Control, *review*, 515
Temple-Boreham, E. W. : Appointed senior game warden, Kenya, 234
Tenebrio and *Tribolium* Occurrence of Cholinesterase in (R. D. O'Brien), 162
Terminology of Enzyme Formation (M. Cohn, Dr. J. Monod, M R. Pollock, S. Spiegelman and R. Y. Stanier), 1096
Terramycin and Aureomycin : Avidity of, for Metallic Cations (Prof. Adrien Albert), 201
Terrestrial Magnetic Field in the *E*-Layer : Measurements of the (Dr. M. Cutolo), 774
Terry, R. A. (Ferguson, W. S., and) · Purines in Grassland Herbage, 346
Tertiary Amines Compounds of, with Nitrosyl Chloride and with Dinitrogen Tetroxide (Dr. Alan E. Comyns), 491
Tertiary Floras, 1090
Tertiary Marsupial Fluorine Tests in Australia on the Keilor Skull and a (Edmund D. Gill), 409
Testing of Two Samples (Dr. P. V. Krishna Iyer), 553
Textile Industry (British) · Recruitment of Higher Personnel for the, 707
Textile Institute, Manchester Address to the Autumn Convocation (Sir E. Raymond Streat), 707
Textile Technology : Postgraduate Research Scholarships in (Courtaulds' Scientific and Educational Trust Fund Awards), 383
Textile, Plastics and Allied Industries : Postgraduate Research Scholarships in the (Courtaulds' Scientific and Educational Trust Fund Awards), 383
Texture of Catalysts Structure and (Société de Chimie Physique Conference on), 986
Thelytokous Parthenogenesis for Four Generations in the Desert Locust (*Schistocerca gregaria* Forsk) (Acrididae), (Dr. A. G Hamilton), 1153
Theobroma cacao L. : Sterility in (R. Knight and H. H. Rogers), 164
Theoretical Nuclear Physics (Prof. John M. Blatt and Prof. Victor F. Weisskopf), *review* by Dr. K. J. Le Couteur, 785
Théorie hydrothermodynamique des explosions et des chocs : État actuel et valeur de la (Dr. S. Travers), Première partie et Deuxième partie, *review* by Prof. D. M. Newitt, 699
Théories de l'univers en expansion (Paul Couderc), 571
Theory : Information (Dr. P. M. Woodward), 58
Theory of Alternative Genetic Pathways : A Relationship between Dominance, Phenotypic Stability and Variability, and a (Dr. D. Lewis), 1136
Theory of Control in Mechanical Engineering : An Introduction to the (R. H. Macmillan), *review* by Prof. J. Greig, 91
Theory of the Living Organism A Contribution to the (Prof. W. E. Agar), second edition, *review*, 223
Theory of Revertible Mutations (Dr. D. Lewis and Leslie K. Crowe), 501
Theory of Wing Sections (Ira H. Abbott and Albert E. von Doenhoff), *review*, 828
Theory and Applications of Fluid Dynamics, *review*, 600
Therapeutics . The Pharmacist and (Dr. G. R. Boyes), 651
Thermal Anomaly in the Elastic Constants of Chromium (H. Pursey), 864
Thermal Contraction of Collagen and its Dissolution with Elastase (Dr. I. Banga), 1099 ; (Dr. D. A. Hall, Prof. R. E. Tunbridge and G. C. Wood), 1100
Thermal Convection · Heat Transfer from Water to Ice by (J. M. Dumoré, H. J. Merk and Prof. J. A. Prins), 460
Thermal Decomposition of Dolomite (Dr. Robert Meldau and Robert H. S. Robertson), 998
Thermal Treatment of Non-Ferrous Metals and Alloys . Equipment for the (Institute of Metals), *review* by Prof. F. C. Thompson, 1067
Thermobalance · Differential—a New Research Tool (Prof W. L. De Keyser), 364
Thermodynamics of Irreversible Electro-chemical Phenomena (Prof. S. R. de Groot, P. Mazur and H. A. Tolhoek), 497 ; (Peter H. Kemp), 498
Thermo-remanent Magnetism (Reverse) . Origin of, of Igneous Rocks (Prof. T. Nagata, S. Akimoto and S. Uyeda), 630
Thermo-remanent Magnetization of Igneous Rocks : Self-Reversal of (Prof. Takesi Nagata), 850
Theses accepted for Higher Degrees in the Universities of Great Britain and Ireland · Index to (Aslib), Vol. I, 985
Thiamine Contents of Saffron, *Crocus sativus* Linn. : Riboflavine and (Prof. J. V. Bhat and Rajal Broker), 544
Thiamine Triphosphate in Bakers' Yeast (K.-H. Kiessling), 1187
Thick Liquids, Pastes and Slurries : Mixing of (British Society of Rheology Symposium on), 384, 846
Thickness, Solid and Water Concentration in Living Cells : Determination of Dry Mass, (Dr. R. Barer), 1097
Thilo, Prof. E. : Elected president of the Chemische Gesellschaft in der Deutschen Demokratischen Republik, 709
Thimann, Prof. K. V. Chemical Structure in relation to Plant Growth-Regulating Activity, 710
Thimann, Prof. K V. (Stowe, Bruce B., and) : Indolepyruvic Acid in Maize, 764
Thionyl Chloride · Action of, on Carboxylic Acids in the presence of Pyridine (J. A. Cade and Dr. W. Gerrard), 29
Thirumalachar, Dr. M. J. (Pavgi, M. S , and) . Angular Black Spot Disease of Mung Beans, 314
Thomas, G. : Plastic Deformation of Metals, 572
Thomas, J. Awarded a Wellcome Pharmaceutical Research Fellowship for a second year, 280
Thomas, Dr. L. F., and others : Microwave Spectrum of Penta-1 : 3-diyne 771
Thomas, L R. : Chemical Processes and Chemical Engineering Techniques 711
Thomas, Miss Mary D. · Awarded a British Memorial Fund Fellowship o the State of Victoria, Australia, 59
Thomas, R. (Jermyn, M. A., and) : Reduction of Liquid Flow in Pape Electrophoresis, 728
Thomasson, H. J. : Biochemical Problems of Lipids, 574
Thompson, B. W. (Yeo, D., and) : Deposition of a Coarse Aerosol release from a Low-flying Aircraft, 168
Thompson, Prof. F. C. : The London Mint, *review*, 221
  Aspects of Modern Metallurgy, *review*, 1067
Thompson, M. A. : Impurity Phenomena, 385
Thompson, Prof. R. H. S. : Anticholinesterases, 844
Thompson, R M. · Appointed geologist, British Solomon Islands Protectorate, 753
Thomson, Andrew · Arctic Meteorology, 1167
Thomson, Sir Landsborough · Birds of East Africa, *review*, 92
Thomson, Dr. S. J., and others : Cosmic-Ray Production of Helium i Meteorites and their Ages, 1168
Thoracic Glands of *Iphita limbata* Stal. (Dr. K. K Nayar), 768
Thorium B (Lead)-binding Substance from the Erythrocytes of Rabb Blood (Dr. K. K. Reddi), 202
Thornthwaite, Dr C. W. : Micrometeorology, 1167
Thorold, C. A. : Appointed principal research officer, Nigeria, 234
Thorotrast in the Body . Tissue Dosage from (Prof. J. Rotblat and Gillia B. Ward), 769
Thouless, Dr R. H., and others · Statistical Significance in Psychical Research, 594
Three Hundred Years of American Psychology, *review* by Prof. John Cohen 599
Three-Dimensional Films (H Dewhurst), 484
Thresh, H. R. · Appointed a Research Fellow in industrial metallurgy at the University of Birmingham, 1084
Thring, Prof. M. W. Eddies in Turbulent Jet Diffusion Flames, 634
Thromboplastin in Shed Mammalian Blood : Formation of (Dr. P. Fantl and R A. Hayes), 303
Thrush, B A., and others : Chemiluminescent Phenomena during Hydrocarbon Combustion, 71
Thunberg, Prof. T. · *Obituary* by Prof. F. G. Young, 1079
Thurmond, C. D. : Impurity Phenomena, 386
Thymocytes (Rat) · Effect of Ultra-violet Light on Deoxyribonucleic Acid in (S. J. de Courcy, Jun., J. O. Ely and M. H Ross), 419
Thyroid · Effect of Diuresis on Uptake of Radioiodine (^{131}I) by the (Dr J. Pahaut, Dr. J. Govaerts and Dr. P. Bonhomme), 545
Thyroid Hypofunction and the Development of the Central Nervous System (Dr. J T. Eayrs), 403
Thyroid-stimulating Hormone, Thyroid and Thyroid-like Substances on *Xenopus* Tadpoles Assay of (J. M. Dodd and Prof. F W Landgrebe), 121
Thyroxine Effect of, on Coenzyme A Levels (Irving I. A. Tabachnick and Prof. Desmond D. Bonnycastle), 400
Tides Between the (Philip Street), *review* by Dr D P. Wilson, 884
  Waves and (R C. H. Russell and Comdr. D. H Macmillan), *review* by K. F Bowden, 268
Tietz, Miss Alisa Granted a Glaxo Laboratories Research Fellowship through the Friends of the Hebrew University, 187
Tiffany, Lewis Hanford, and Britton, Max Edwin · The Algae of Illinois, *review* by Prof. F E. Fritsch, 268
Tilapia in East Africa . New Fish Culture Methods for (J. M Brown and Dr. Vernon D. van Someren), 330
Tilapia esculenta Graham : Feeding Mechanism of the Cichlid Fish (P. H. Greenwood), 207
Tiller, L. W. · Appointed an assistant secretary to the Department of Scientific and Industrial Research, New Zealand, 333 ; work of, 333
Tillotson, Ernest : Earthquake Swarm in the Ionian Sea, 332
Timber . Sterilization of, with Methyl Bromide (J B. Cartwright, D. W Edwards and M. J. McMullen), 552
Timber Progress and Desk Book for 1953 (edited by W. E Bruce), *review* by Prof. E. P. Stebbing, 374
Timbrell, Dr. V. : Generation of Weak Shock Waves, 540
Time Judgment A New Phenomenon in (Prof John Cohen, C. E. M. Hansel and J. D. Sylvester), 901
Time-Lag in E_k Potentials (Dr. S. D. Elek and E. S. Boatman), 1056
Time Series : A Suggested Alternative to the Correlation Coefficient for testing the Significance of Agreement between Pairs of, and its Application to Geological Data (T. P Burnaby), 210
Time Service (Greenwich) : Quartz Clocks of the (H. M. Smith), 984
Tin Films Determination of the Structure Factor of Thin, from Superconductivity Measurements (Prof A. Van Itterbeek, L. De Greve, L. Van Gerven and J. Schepers), 952
Tlone, J. E. . Appointed lecturer in bacteriology at the University of Glasgow, 1030
Tissue (Mouse Connective) . Extraction of a Heparin-like Substance from Mast Cell Granules in (Dr. M. Koksal), 733
Tissue Dosage from Thorotrast in the Body (Prof. J. Rotblat and Gilliam B. Ward), 769
Tissue Fractionation · Reproducibility of Differential Centrifugation Experiments in (Prof. C. de Duve and J. Berthet), 1142
Tissue System . Conversion of *δ*-Aminolaevulinic Acid to Porphobilinogen in a (Dr. E. I. B. Dresel and Dr. J E. Falk), 1185
  Porphobilinogen as a Porphyrin Precursor, and Interconversion of Porphyrins, in a (Dr. J E. Falk, Dr. E. I B. Dresel and C. Rimington), 292
Titanium, a Metal of Engineering Importance (Major P. L. Teed), 608
Titanium and its Alloys in Engineering : Importance of, 608
Toad (*Xenopus laevis*) (South African Clawed) . Budding of Erythrocytes in the, after Splenectomy (Marcus Jacobson), 1107
Tobacco Plants · Some Effects of Mosaic Virus on Nitrogen and Phosphorus Metabolism in (Dr. Rupert J. West and H. P. C. Gallus), 347
Tobacco Mosaic Virus Antigen · Radioautographic Study of the Localization of (Dr. F. Gavosto and Mrs. A. Ficq), 406
Tocopherol : Effect of Tri-*ortho*-cresyl Phosphate on the Absorption of (D. K. Myers and H. E. W. Mulder), 773
Todd, Prof. A. R., and others : Structure of Adenylic Acids *a* and *b*, 1184

odrick, Dr. A. · Anticholinesterases, 843
olbe, Dr. M. K., and Eskarous, Mrs. Josephine K. : Effect of Five Strains of Fowl-Plague Virus on a Sulphonphthalein Dye, 961
olerance' 'Actively Acquired, of Foreign Cells (Dr. R. E. Billingham, L. Brent and Prof. P. B. Medawar), 603
olhoek, H. A., and others · Thermodynamics of Irreversible Electrochemical Phenomena, 497
omato Seed · Stimulation of the Growth of the Radicle after Treatment of, with Bromine Water (William G. Boll), 963
omato Spotted Wilt in Dried Plant Material : Preservation of the Virus of (Dr. Rupert J. Best and H. P. C. Gallus), 315
omatoes (Glasshouse) : Combined Hormone-Fungicide Sprays for Control of *Botrytis* Fruit-Rot in (F. J. Newbook and R. M. Davison), 351
omkeieff, Dr. S. I. : Geological Structure of the Russian Platform, 751
ompkins (Mr.) Learns the Facts of Life (Prof. George Gamow), *review* by W. L. Sumner, 741
opography · Young Morainic, in Holderness (Dr. Hartmut Valentin), 919
opology of Plane Sets of Points : Elements of the (Prof. M. H. A. Newman), second edition, *review* by Dr. R. G. Cooke, 325
orrance, J. H. S. : Awarded a Postgraduate Scholarship in Agricultural Engineering by the Department of Agriculture for Scotland, 840
Torrey, Prof. Ray E. *Obituary* of Prof. E. C. Jeffrey, 653
erulae Haploid ? : Are (Dr. M. K. Subramaniam and B. Ranganathan), 628
otta, Paul A., and others : Score Resistance of Bearing Metals, 301
owers, G. H. N., and Gibbs, Prof. R. Darnley : Lignin Chemistry and the Taxonomy of Higher Plants, 25
wn and Village · Birds of (R. S. R. Fitter), *review* by L. J. F. Brimble, 324
oxic Fluorine Compounds (Dr. F. L. M. Pattison), 1139
oxic Hazards of Pesticides to Man (Dr. George C. Decker), 1125
oxicity of Dihydrostreptomycin : Protective Activity of Cysteamine against the (P. Kruyskens), 912
Toxicity of Radiostrontium in Monkeys (G. M. Edington, J. M. Judd and Dr. A. H. Ward), 122
Toxicity and Activity of Nitrogen Mustard . Influence of Cysteamine, Methylamine and Cortisone on the (Dr. O. Peczenik), 454, *erratum*, 942
Toxicity Studies on Silicone Rubber and other Substances (Dr. John D. B. MacDougall), 124
Tracer Mineral : Nosean as a (Dr. A. G. Lowndes), 636
Tracheids of Vascular Plants from the Vindhyan System, India : Spores and —the Advent of Vascular Plants (Dr. K. Jacob, Mrs. Chinna Jacob and R. N. Shrivastava), 166
Tracheoles (Insect) : Motility of (Prof. V. B. Wigglesworth), 247
Trade, Board of . Allotment of £8,455 as a Conditional Aid Project (United States) for research on the wool textile industry, to be conducted in the Department of Economics in the University of Leeds, 895
Training for Management (British Association for the Advancement of Science, Sections F (Economics) and L (Education), Discussion on), 693
Trans-Atlantic Telephone Cable, 1129
Transaminase . Aspartate-Glutamate, in a Red Halophilic Bacterium (J. Robinson and H. Katznelson), 672
Transfer Problems : Basic Methods in—Radiative Equilibrium and Neutron Diffusion (V. Kourganoff, with the collaboration of I. W. Busbridge), *review* by Prof. W. H. McCrea, 924
Transferase Activity of Hydrolytic Enzymes (Dr. R. K. Morton), 65
Transients in Communication Engineering . Harmonics, Sidebands and (C. Louis Cuccia), *review* by F. Horner, 5
Transition Temperature of Insect Cuticular Waxes : A New Method for Determining the (P. J. Judge), 405
Transition Temperatures (Mesomorphic and Polymorphic) : A Heating Instrument for the Accurate Determination of (Dr. G. W. Gray), 1137
Transmutation of the Elements (British Association for the Advancement of Science, Section B (Chemistry), Discussion on), 606
Transphosphorylation between Nucleoside Polyphosphates (P. Berg and W. K. Joklik), 1008
Transplantation of Nuclei in Newt's Eggs (Prof. C. H. Waddington and E. M. Pantelouris), 1050
Transport, Ministry of . Report of the Committee on the Prevention of Pollution of the Sea by Oil, 1013
Transverse Cracks in Glass Rod (E. R. W. Jones and P. L. Pratt), 463
Travel Grants under the Fulbright Programme (United States Educational Commission in the United Kingdom), 1030
Travelling Disturbances in the Ionosphere (R. E. Price), 155
Travelling Disturbances in the Ionosphere Investigation of, by Continuous-Wave Radio (Y. V. Somayajulu), 818 ; (B. Ramachandra Rao and E. Bhagiratha Rao), 819
Travers, Dr. S. : État actuel et valeur de la théorie hydrothermodynamique des explosions et des chocs, Première partie et Deuxième partie, *review* by Prof. D. M. Newitt, 699
Tree Seedlings · Growth Response of, to Mycorrhizal Mycelia in the Absence of a Mycorrhizal Association (Dr. Ida Levisohn), 316
Tree-Spotting in Malaya, *review* by Dr. N. L. Bor, 827
Trees of Malaya Wayside (E. J. H. Corner), second edition, *review* by Dr. N. L. Bor, 827
Treloar, Dr. L. R. G. · Polymer Science, 102
  Elected president of the British Society of Rheology, 709
Trevan, Dr. J. W. : Retirement as director of the Wellcome Research Laboratories, Beckenham, and temporary director of research in the Wellcome Foundation, Ltd., 654 , work of, 654
Trevor, Dr. J. C. : Race Crossing in Man, *review* by Dr. H. Grüneberg, 137
  A New Fossil Man from South Africa, 652
Trevor, Dr. J. C., and others : A Fossil Human Mandible from a Levalloiso-Mousterian Horizon in Cyrenaica, 889
Tri-chloromercury-oxonium Chloride : Mercuric Oxychloride as (D. Grdenić and S. Ščavničar), 584
Tri-ortho-cresyl Phosphate : Effect of, on the Absorption of Tocopherol (D. K. Myers and H. E. W. Mulder), 773
Tri-Soaps (Aluminium) · Preparation of (Dr. R. C. Mehrotra), 74
Tria, Dr. E., and Barnabei, Dr. O. : An Unidentified Growth-Factor for Yeast and Hyperthyroid Rats, 203
Tribolium · Occurrence of Cholinesterase in *Tenebrio* and (R. D. O'Brien), 162
Trichostrongylus retortaeformis : Phenomenon of Protection in Infections of (J. F. Michel), 312
Trier, P. E., and Knott, G. Appointed joint managers of the Mullard Research Laboratories, 100 ; work of, 100
Trinity College, Dublin : Appointment of Dr. W. D. Gill to the chair of geology and mineralogy, 1082
Triplex Safety Glass Co., Ltd. : Booklet on Philosophy for Management, 612
Triticum × *Secale* Hybrid : Behaviour of a, under the Action of Colchicine (Prof. Edmond Villax and Miguel Mota), 412
Tropane and Hygrine Bases : A Possible Common Biogenetic Origin of the Nicotine, (P. I. Mortimer), 74
Tropical Rain Forest, an Ecological Study (Prof. P. W. Richards), *review* by Dr. W. B. Turrill, 177
Tropical Soils Relation of Witchweed (*Striga*) to Fertility in (K. Wilson Jones), 128
Tropics : Radio-Astronomy in the (Prof. H. E. Huntley), 108
Truant from the Psychoanalytical School, *review* by Dr. Clifford Allen, 827
Trueman, Sir Arthur Recruitment of American Scientists, *review*, 373
Trump, Harold J. · Appointed director of extra-mural studies in the University of Glasgow, 1030
Trumpler, Robert J., and Weaver, Harold F. · Statistical Astronomy, *review* by Prof. W. M. Smart, 1017
Trusts and Foundations (compiled by Guy W. Keeling), edited by Thomas Landau, *review*, 1069
Trypanosomiasis (Bat) : Fortuitous Xeno-diagnosis of (Dr. R. B. Heisch and Prof. P. C. C. Garnham), 248
Tryptamines : A Fluorescence Test for Serotonin and other (Dr. John B. Jepson and B. J. Stevens), 772
Tryptic Hydrolysis of Casein *in vitro* : Action of Duck's Egg White Ovomucoid on (P. K. Vijayaraghavan and B. S. Narasinga Rao), 1152
Tryptophan Metabolism : A Disturbance of, in Congenital Hypoplastic Anaemia (Prof. K. I. Altman and Gerald Miller), 868
Tryptophane Metabolism in Rice Moth Larva (*Corcyra cephalonica* St.), (T. K. Sundaram and P. S. Sarma), 627
Tryptophane Metabolites in Human Urine (Dr. M. Spaček), 204
Tuberculosis : Random Choice in the Chemotherapy of, *review* by Dr. Vincent C. Barry, 322
Tull, Dr. V. F. G. (Burger, Dr. F. J., and) : Gas Content and Electrolytic Etching Behaviour of Aluminium, 729
Tulloch, Prof. W. J. : *Obituary* of Dr. M. H. Gordon, 438
Tumour (Carcinoid) : 5-Hydroxytryptamine in a (Dr. F. Lembeck), 910
Tumours (Pulmonary) . Linkage between, and Vestigial Tail in the House Mouse (Dr. W. E. Heston), 1007
Tunbridge, Prof. R. E., and others . Thermal Contraction of Collagen and its Dissolution with Elastase, 1100
Tunicates Reversal of the Heart-beat in (C. A. Haywood and Prof. H. P. Moon), 40 ; (Dr. R. H. Millar), 41
Tunicin-forming Blood Cells of an Ascidian . Discovery of Iron in (R. Endean), 123
Tupllin, Prof. W. A. : The Teaching of Mechanics, 898
Turbidity-reducing Activity of Influenza Virus and Receptor-destroying Enzyme on Sheep Submandibular Mucoid (Dr. J. F. McCrea), 912, 1173
Turbines (Gas) · Use of Peat for, in Scotland, 186
Turbulent Jet Diffusion Flames : Eddies in (Prof. M. W. Thring), 634
Turk, Dr. W. E. : Current Types of Photomultipliers, 279
Turner, Prof. E. E., and Harris, Dr. Margaret M. : Organic Chemistry, *review* by Dr. J. D. Loudon, 135
Turner, J. F. : Synthesis of Sucrose by a Plant Enzyme Extract, 1149
Turner, J. S. : Awarded an Overseas Scholarship for 1953 by the Royal Commission for the Exhibition of 1851, 17
Turner, Prof. W. E. S. : Elected honorary president of the International Commission on Glass, 287
Turner and Newall, Ltd. : Renewal of a gift of £600 a year for seven years to the University of Leeds for Fellowships in engineering, inorganic chemistry or physics, 983
Turney, A. : Electrical Insulation, 9
Turnock, Mrs. Dorothy : Paper Chromatography of Keto-Acids, 355
Turquette, Prof. Atwell R. (Rosser, Prof. J. Barkley, and) : Many-valued Logics, *review* by F. L. G. Rawlins, 928
Turrill, Dr. W. B. . Ecology of the Tropical Rain Forest, *review*, 177
  Methods of the Experimental Ground in relation to Taxonomy, 233
Turtles on the British Coasts : Guide to the Identification and Reporting of Stranded Whales, Dolphins, Porpoises and (F. C. Fraser and H. W. Parker), second edition, 334
Tveit, M. : Control of a Seed-borne Disease by *Chaetomium cochliodes* Pall., under Natural Conditions, 39
Twins : The Psychiatry of, *review* by Dr. Clifford Allen, 739
  Psychotic and Neurotic Illness in (Eliot Slater, with the assistance of James Shields), *review* by Dr. Clifford Allen, 739
Two-dimensional Paper Chromatography of Radioactive Substances (F. P. W. Winteringham), 727
Two-dimensional Representation of Solid Objects . Use of Non-geometrical Perspective in the (Philip Short), 1002
Tyabji, S. F. B. Classical Considerations on the Abnormal Properties of Helium-4, 849
  Equations of Motion for Continuous Matter of Special Relativity in the Lagrange Variables, 1147
Tyndall, Prof. A. M. · Dielectrics, 564

UBISCH, L. v. · Entwicklungsphysiologie, *review* by Dr. James Needham, 739
Ulmus · The European Cortina-Ulisse Prize for 1953, 60
Ultra-short-wave Field-strength in a Ground-based Radio Duct (R. S. Unwin), 856
Ultrasonic Treatment : Abnormal Embryonic Development in *Drosophila* Induced by (G. G. Selman and S. J. Counce), 503
Ultrasonics and Optics : Recent Developments in (Physical Society Summer Provincial Meeting on), 443
Ultra-Violet Absorption Spectra of their Ions : Identification of Flavones by the (G. H. Mansfield, Dr. T. Swain and C. G. Nordström), 23
Ultra-Violet Absorption Spectra and Flow Birefringence of Bovine Cervical Secretions (P. A. Glover), 255
Ultra-Violet Absorption Spectrum of Asparagine : Contribution of the, to the Problem of its Structure (Leo J. Saidel), 955
Ultra-violet Light on Deoxyribonucleic Acid in Rat Thymocytes : Effect of (S. J. de Courcy, jun., J. O. Ely and M. H. Ross), 119

Ultraviolet Spectra of Aromatic Compounds (Dr. Robert A. Friedel and Dr. Milton Orchin), *review* by Dr. E. Clar, 223
Umbellulone : Some New Derivatives of (the late Dr. A. E. Gillam and D. G. Moss), 585
Uncertainty : Logic, Philosophy and Psychology of Business Decision-making under (British Association for the Advancement of Science, Section F (Economics), Symposium on), 701
Uncertainty, Expectation and Decision in Business Affairs (Prof. G. P. Meredith), 701
Undergraduate Laboratory Teaching (American Association of Physics Teachers Discussion on), 339
Underhill, Anne B. : Spectrophotometric Comparison of the Shell Spectrum of ζ Tauri, 279
Underwater Exploration by 'Aqualung', *review* by Dr. A. J. Brook, 370
Undeveloped World : Our (L. Dudley Stamp), *review* by Sir John Russell, 266
Unesco, and others : Conference on Optics and Microwaves, 102
Unesco Science Co-operation Office for Latin America : Report for 1952, 440
Unesco South Asia Science Co-operation Office : Bibliography of Scientific Publications of South Asia, No. 7, India, Burma and Ceylon, January–June 1952, 234
Unfertilized Rabbit Ova : Storage of— Subsequent Fertilization and the Probability of Normal Development (Dr. M. C. Chang), 353
Unit Cell and Preliminary Structure for Cellulose Triacetate (W. J. Dulmage), 1053
United Kingdom : MSF—New Programme of Experimental Frequency Transmissions from the (National Physical Laboratory), 529
  Standard Frequency Transmissions from the, 529
  A Survey of Agricultural, Forestry and Fishery Products in the, and their Utilization (Development Commission), 574
United Kingdom Agricultural Representatives in the United States, 654
United Kingdom Atomic Energy Project : White Paper on the, 939
United States : Commonwealth Fund Fellowships for Study and Travel in the, 611
  Financing Higher Education in the (John D. Millett), *review* by Sir Hector Hetherington, 470
  Library Facilities in the (R. W. L. Collison), 191
  Medical Research in the (K. M. Endicott and E. M. Allen), 1172
  Research and Development at Non-profit Institutions in the, 575
  United Kingdom Agricultural Representatives in the, 654
U.S.A. : The BCSO Review of Science in, for the Year ending June 1952 (British Commonwealth Scientific Office, North America), 282
United States Economic Aid : White Paper on Programme of Expenditure of Counterpart Funds derived from, 528
United States Educational Commission in the United Kingdom : Travel Grants under the Fulbright Programme, 1030
United States Federal Research and Development Funds, 575, 1171
United States Government, Foreign Operations Administration : Research Fellowships in the United States for Young European Scientific Workers, 569
United States National Museum : Annual Reports for 1951 and 1952, 232
United States National Science Foundation : Fellowship Awards and Research Grants, 102
  Federal Funds for Science, 1, Federal Funds for Scientific Research and Development at Non-profit Institutions 1950–51 and 1951–52, 575
  Completion of Research Awards for 1953, 613
  Appointment of Dr. Laurence McKinley Gould to the Board, 709
  Finances of the, 753
  Federal Funds for Science, 2, Federal Funds for Scientific Research and Development for the Fiscal Years 1952 and 1953, 1171
United States Office of Naval Research, and others : Symposium on Plasticity, 17
United States Office of Naval Research and the University of Pennsylvania : Symposium on the Origins of Resistance to Drugs, 754
United Steel Companies, Ltd. : Establishment of a research fellowship in metallurgy in the University of Sheffield, 753
l'Univers en expansion : Les théories de (Paul Couderc), 571
Universities (British) : Teaching of Mechanics in (R. H. Macmillan), 898
Universities and their Faculties : The Rights and Responsibilities of (Association of American Universities), 217, 598, 641
Universities of the Commonwealth, Congress of : Discussion on Higher Technological Education, 270
  Discussion on Academic Mobility in the Commonwealth, 271
Universities of Great Britain : Freedom of the, 173
Universities of Great Britain—Position and Prospects, 180
Universities of Great Britain and Ireland : Index to Theses accepted for Higher Degrees in the (Aslib), Vol. 1, 985
Universities' Council for Adult Education : Report for 1951–52, 283
Universities Federation for Animal Welfare : Summer School, 336
University : Links between School and, 382
  The Output of a, *review* by Prof. F. J. M. Stratton, 825
  The Purpose of a, 131
  The Social Function of the (Sir Hector Hetherington), 132
University of Berlin : Free (Prof. W. O. L. Heubner), 942
University of Birmingham : Conference on Nuclear Physics, 59
  Postgraduate Engineering Production Courses in the (Prof. T. U. Matthew), 59
  Grant of £28,000 from the Rockefeller Foundation of New York to the Department of Experimental Psychiatry for research in Psychiatry, and the Biochemistry and Pharmacology of the Nervous System, 145
  Conference on the Structure of the Atomic Nucleus, 486
  Proton Synchrotron of the, 704
  Appointment of Prof. A. J. Murphy as director of the Combined Departments of Metallurgy, 709
  Title of University Research Fellow in physics conferred on Dr. F. Aughtie, 709
  Title of University Research Fellow in electron physics conferred on Dr. G. F. Alfrey, 709
  Appointment of A. J. Williams as a Research Fellow in the Department of Metallurgy, 709
  Title of reader in medical statistics conferred on Dr. J. A. H. Waterhouse, 1084
  Resignation of Dr. P. L. Krohn from the readership in endocrinology in order to accept a Nuffield Gerontological Research Fellowship tenable in the Department of Anatomy, 1084
  Appointment of Dr. E. J. Hamley as lecturer in physiology, 1084
  Appointment of P. Reasbeck as I.C.I. Fellow in physics, 1084
  Appointment of Dr. F. M. Mohtadi as I.C.I. Fellow in chemical engineering, 1084
  Appointment of R. T. Allsop and H. R. Thresh as Research Fellows in industrial metallurgy, 1084
  Appointment of Dr. M. A. A. Jorro as Research Fellow in metallurgy, 1084
  Appointment of Dr. R. S. Aitken as vice-chancellor, 1170
University of Bristol : Jubilee Celebrations of the Long Ashton Research Station (R. W. Marsh), 273
  Conference on Plastic Deformation of Metals, 572
University of Cambridge : Award of a Fellowship by King's College, 18
  Informal Discussions in the Department of Engineering on the Teaching of Mechanics, Vibrations and Control, 898
  Appointment of Prof. N. F. Mott to the Cavendish chair of experimental physics, 1128
University of Chicago : Post-doctoral Fellowships in Statistics, 613
University of Dacca : Appointment of Dr. W. A. Jenkins as vice-chancellor, 797
University of Durham : Retirement of Prof. F. A. Paneth as professor of chemistry, 611
  Appointment of Prof. G. E. Coates as professor of chemistry, 611
University of Edinburgh : Retirement of Prof. Max Born from the Tait professorship of natural philosophy, 1082
  Appointment of Prof. N. Kemmer to the Tait professorship of natural philosophy, 1082
University of Florida, State : Research Studies No. 9, 1131
University of Glasgow : Appointment of Harold J. Trump as director of extramural studies, 1030
  Appointment of Dr. Ian M. Dawson as senior lecturer in electron microscopy, 1030
  Appointment of R. Common as lecturer in geography, 1030
  Appointment of R. H. Cummings as lecturer in geology, 1030
  Appointment of B. E. L. Deckker as lecturer in mechanical engineering, 1030
  Appointment of W. M. Fairbairn and A. Geddes as lecturers in mathematics, 1030
  Appointment of A. Fraser as lecturer in agricultural zoology, 1030
  Appointment of K. M. Guggenheimer as lecturer in natural philosophy, 1030
  Appointment of R. G. Hemingway as lecturer in agricultural chemistry, 1030
  Appointment of G. W. Hutchinson as lecturer in experimental physics, 1030
  Appointment of J. J. Lewis as lecturer in pharmacology, 1030
  Appointment of Alfred Marr as lecturer in veterinary medicine, 1030
  Appointment of R. G. Moorhouse as lecturer in theoretical physics, 1030
  Appointment of G. H. Nancollas as lecturer in chemistry, 1030
  Appointment of J. E. Tinne as lecturer in bacteriology, 1030
  Appointment of A. H. De Borde and Derek Oldroyd as Nuffield Fellows in the Department of Natural Philosophy, 1030
  Appointment of W. G. V. Romer as D.S.I.R. Research Fellow in the Department of Natural Philosophy, 1030
University of Hong Kong : Fisheries Research Vessel *Alister Hardy* of the Fisheries Research Unit, 1170
University of Leeds : Annual Report of the Librarian, 143
  Appointment of Dr. R. D. Preston as professor of plant biophysics, 187, 231
  Absence of leave granted to Dr. W. A. Sledge for the second term of session 1953–54, 187
  Gift of £1,350 from Courtaulds, Ltd., to the Clothworkers' Departments, 187
  Gift of £1,500 from the Department of Scientific and Industrial Research to the Department of Inorganic and Physical Chemistry, 187
  Retirement of Prof. N. M. Comber as head of the Department of Agriculture and professor of agriculture, 278
  Appointment of Prof. T. L. Bywater as head of the Department of Agriculture and professor of agriculture, 278
  Booklets on the courses available in Science and Technology, 382
  Annual Report for 1951–52, 382
  Reports on the Departments of Textile Industries and Colour Chemistry and Dyeing for 1950–51 and 1951–52, 388
  Title of emeritus professor of organic chemistry conferred on Prof. F. Challenger, 895
  Title of emeritus professor of agricultural chemistry conferred on Prof. N. M. Comber, 895
  Title of emeritus professor of experimental pathology conferred on Prof. R. D. Passey, 895
  Title of emeritus professor of geography conferred on Prof. A. V. Williamson, 895
  Appointment of F. A. Leeming as lecturer in the Department of Geography, 895
  Appointment of P. H. Broadhurst as lecturer in the Department of Mining, 895
  Appointment of A. Grounds and L. W. Needham as honorary lecturers in mineral dressing and coal preparation, 895
  Appointment of J. McFarlane as Hugh Wood Memorial Fellow in the Department of Mining, 895
  Renewal by the Worshipful Company of Clothworkers of three grants (special maintenance grant, a research grant, and a Dyeing Department research grant) for the Clothworkers' Department, 895
  Grant of £350 from the British Dyewood Co., Ltd., Glasgow, for postgraduate research in the Department of Colour Chemistry and Dyeing, 895
  Grant of £600 from the Medical Research Council for the maintenance of a research worker and the expenses of research in microbiological chemistry in the Department of Biochemistry, 895
  Grant of £500 from May and Baker, Ltd., Dagenham, for research in the Department of Pharmacology, 895
  Grant of £8,455 allotted through the Board of Trade as a Conditional Aid Project (United States) for research on the Wool Textile Industry, 895
  Grant of £4,000 from the National Coal Board, 895
  Dr. S. Mackey to go on leave as professor of civil engineering at the Indian Institute of Technology at Kharagpur, 983

Renewal of a gift of £750 a year for two years to the Department of Pharmacology from the Wellcome Research Laboratories, 983
  Gift of £315 to the Department of Pharmacology from Boots Pure Drug Co., Ltd., 983
  Renewal of a gift of £600 a year for seven years from Turner and Newall, Ltd., for Fellowships in engineering, inorganic chemistry or physics, 983
  Retirement of Prof. R. D. Passey from the chair of experimental pathology and cancer research, 1028
  Appointment of Prof. H. N. Green to the chair of experimental pathology and cancer research, 1028
University of Liverpool (1903–53), (Sir Henry Cohen), 271
University of London : Election of Sir Roderic Hill as vice-chancellor, 18
  Re-appointment of Sir Alexander Carr-Saunders as deputy vice-chancellor, 18
  Appointment of Dr. R. A. Shooter to the University readership in bacteriology at St. Bartholomew's Hospital Medical College, 60
  Title of professor of organic chemistry in the University conferred on Dr. D. H. R. Barton, 60
  Title of reader in chemistry in the University conferred on Dr. Allan Maccoll, 60
  Retirement of Prof. H. R. Robinson from the chair of physics in Queen Mary College, 100
  Appointment of Dr. G. O. Jones to the chair of physics in Queen Mary College, 100
  Seminar at University College on Polymer Science, 102
  Appointment of Dr. W. St. C. Symmers to the University chair of morbid anatomy at Charing Cross Hospital Medical School, 103
  Appointment of Dr. J. H. F. Brotherston to the University readership in public health at the London School of Hygiene and Tropical Medicine, 103
  Title of professor emeritus of mathematics in the University conferred on Prof. W. G. Bickley, 234
  Title of professor emeritus of plant pathology in the University conferred on Prof. William Brown, 234
  Title of professor emeritus of zoology and applied entomology in the University conferred on Prof. J. W. Munro, 234
  Title of professor emeritus of physics in the University conferred on Prof. H. R. Robinson, 234
  Title of professor emeritus of physics in the University conferred on Prof. Gilbert Stead, 234
  Appointment of J. R. Ashby to the University readership in civil engineering at the Imperial College of Science and Technology, 234
  Appointment of Dr. C. C. Butler to the University readership in physics at the Imperial College of Science and Technology, 234
  Appointment of Dr. R. M. Goody to the University readership in meteorology at the Imperial College of Science and Technology, 234
  Title of University reader in mathematics conferred on Dr. D. B. Scott, 234
  Lectures on Geographical Exploration To-day arranged by the Department of Extra Mural Studies, 526
  Vacation School on Analysers and Computers for Electrical Systems at the Imperial College of Science and Technology, 614
  Appointment of Dr. P. H. Gregory as head of the Botanical Department and University professor of plant pathology at the Imperial College of Science and Technology, 797, 838
  Retirement of Prof. W. Brown as head of the Botanical Department and University professor of plant pathology at the Imperial College of Science and Technology, 838
  Appointment of Henry S. Darling as head of the Hop Research Department of Wye College, Ashford, 840
  Retirement of Charles Biddolph as senior technician in the Department of Zoology, King's College, 840
  Appointment of Dr. O. W. Richards to the University chair of zoology and applied entomology at the Imperial College of Science and Technology, 895, 1027
  Retirement of Prof. J. W. Munro from the chair of zoology and applied entomology at the Imperial College of Science and Technology, 1027
  Title of University reader in entomology as applied to hygiene conferred on Dr. J. R. Busvine, 1085
  Title of University reader in psychology conferred on Dr. Hildegard T. Himmelweit, 1085
  Appointment of H. Bondi to the University chair of mathematics at King's College, 1131
University of London (Department of Extra Mural Studies) (Atomic Scientists' Association and the) Lectures on Atomic Energy, 1084
University of London (Department of Extra Mural Studies) (British Institute of Recorded Sound, Ltd., in conjunction with the) : Lecture-recitals of sound-recordings in the study of Music, Drama, Literature and Science, 526
University of Lund : Symposium on Chemical Structure in relation to Plant Growth-Regulating Activity, 710
University of Montreal : Honorary doctorates in medicine conferred on Dr. A. D. Adrian and Dr. L. Binet, 1074
University of Mysore : Construction of the Ramnarayan Chellaram College of Commerce, 441
University of Natal . Report of the Wattle Research Institute for 1951–52, 231
University of Nottingham . Appointment of Dr. Rodney Hill to the chair of applied mathematics, 103, 141
  Appointment of Dr. K. W. H. Stevens as reader in theoretical physics, 103
  Gift of £100,000 from C. T. Cripps for the endowment of two professorial chairs, 1129
University of Otago Appointment of Prof. F. G. Soper as vice-chancellor, 1170
University of Oxford : New Physiological Laboratory, 755
University of Padua : Gabriella Zuccari Scholarship for research at the Zoological Station, Naples, 146
University of Pennsylvania (United States Office of Naval Research and the) : Symposium on the Origins of Resistance to Drugs, 754
University of Pittsburgh Conference on Medium-Energy Nuclear Physics, 527
University of St. Andrews : Appointment of Prof. T. M. Knox as principal, 442
  Appointment of Dr. J. Dick to the chair of engineering and drawing in University College, Dundee, 893
University of Sheffield : Appointment of Dr. R. G. Wilkins as lecturer in chemistry, 18
  Appointment of Dr. N. M. Green as lecturer in biochemistry, 18
  Resignation of Prof. E. J. Wayne from the chair of pharmacology and therapeutics, 146
  Resignation of Dr. H. J. Cowan as lecturer in civil engineering, 146
  Appointment of J. F. Fleming as lecturer in civil engineering, 146
  Establishment of a Research Fellowship in Metallurgy by the United Steel Companies, Ltd., 753
  Appointment of K. H. Sutherland and E. P. Bernat as lecturers in mechanical engineering, 753
  Appointment of Dr. W. Eastwood and C. Osgerby as lecturers in civil engineering, 753
  Appointment of F. G. West-Oram as lecturer in glass technology, 753
  New Chemistry Building to be opened by the Earl of Scarborough, 1085
  Honorary degree of LL.D. to be conferred on T. A. McKenna, 1085
  Honorary degree of D.Sc. to be conferred on Sir Cyril Hinshelwood and Prof. C. K. Ingold, 1085
University of Sydney . Appointment of Dr. H. J. Cowan to the chair of architectural science, 568
University of Toulouse . International Conference on Cosmic Radiation, 477
University Affairs in Great Britain 1951–52, 238
University College, Dundee : Appointment of Dr. J. Dick to the chair of engineering and drawing, 893
University College, Ibadan : Report of the Visitors, 231
University College, London : Title of reader in chemistry in the University of London conferred on Dr. Allan Maccoll, 60
  Seminar on Polymer Science, 102
University College of North Staffordshire : Appointment of Dr. F. W. Cope as professor of geology, 709
  Foundation of a Research Studentship in Chemistry by the Polymer Corporation, Ltd., Sarnia, Ontario, for the support of postgraduate research on cationic polymerization, 709
  Foundation of a Fellowship in Chemistry by the Blythe Colour Works, Ltd., Cresswell, for the support of fundamental investigations into inorganic colouring matters, 709
  Appointment of Dr. S. C. Nyburg as the first holder of the Blythe Colour Works, Ltd., Fellowship in Chemistry, 709
  Appointment of Prof. F. Wolverson Cope as professor of geology, 750
University College, Salisbury, Southern Rhodesia, 654
University College of Swansea : Appointment of Dr. J. G. Oldroyd to the chair of applied mathematics, 15
University Development, Report on the Years 1947–1952 (University Grants Committee), 180
University Education in Central Africa, 1
University Expenditure Control of, 535
University Grants Committee : University Development, Report on the Years 1947–1952, 180
  Returns from Universities and University Colleges in receipt of Treasury Grant, Academic Year 1951–52, 238
University Text-Book of Physics, Vol. 3, Heat, being the eleventh edition and a largely rewritten version of Poynting and Thomson's 'Text-Book of Physics', Vol. 3 (J. H. Awbery), *review* by H. L., 1069
University Women, International Federation of : Eleventh Conference, 103, 475
  Election of Officers for 1953–56, 475
  Public Lectures on Human Values in the Technical World, 475
Unknown Acid from Brain Extracts Chromatographed on Silica Gel (F. Friedberg, L. M. Marshall and L. H. Newman), 1191
Unquantized Laws of Electrodynamics . A Simple Formulation of the (Dr. O. Buneman), 859
Unused Land and Hungry People, *review* by Sir John Russell, 266
Unwin, R. S. Ultra-short-wave Field-strength in a Ground-based Radio Duct, 856
Upper-Air Conditions : Atmospheric Ozone and the (Sir Charles Normand), 241
Uptake of Radioiodine (^{131}I) by the Thyroid . Effect of Diuresis on (Dr. J. Pahaut, Dr. J. Govaerts and Dr. P. Bonhomme), 545
Uranates : Alkaline Earth, of the R_3MX_6 Type (E. G. Steward and W. A. Runciman), 75
Uranium : Phase Transformation in (B. R. Butcher and A. H. Rowe), 817
Urbach, Dr. F. . Impurity Phenomena, 386
Urban Areas . Field Studies in (Association of Agriculture and the Joint Biology Committee Conference on), 571, 1032
Urey, Prof. H. C. : Elected a member of the Commission on Geochemical Localization of the Elements of the International Union of Chemistry, 659
Uridine Triphosphate : Uridyl Transferases and the Formation of—Enzymic Production of Uridine Triphosphate, Uridine Diphosphoglucose Pyrophosphorolysis (Agnete Munch-Petersen, Dr. Herman M. Kalckar, Enrico Cutolo and Evelyn E. B. Smith), 1036 ; Uridyl Transferases and the Formation of Uridine Diphosphogalactose (Dr. Herman M. Kalckar, Beatrix Braganca and Agnete Munch-Petersen), 1038 ; Pyrophosphorolysis of Uridine Diphosphoglucose and 'UDPX' by a Rat Liver Nuclear Fraction (Evelyn E. B. Smith, Agnete Munch-Petersen and Dr. George T. Mills), 1038
Uridyl Transferases and the Formation of Uridine Triphosphate—Enzymic Production of Uridine Triphosphate, Uridine Diphosphoglucose Pyrophosphorolysis (Agnete Munch-Petersen, Dr. Herman M. Kalckar, Enrico Cutolo and Evelyn E. B. Smith), 1036 ; Uridyl Transferases and the Formation of Uridine Diphosphogalactose (Dr. Herman M. Kalckar, Beatrix Braganca and Agnete Munch-Petersen), 1038 ; Pyrophosphorolysis of Uridine Diphosphoglucose and 'UDPX' by a Rat Liver Nuclear Fraction (Evelyn E. B. Smith, Agnete Munch-Petersen and Dr. George T. Mills), 1038
Urinary Excretion of Acid and Neutral Deoxyribonuclease by Rats under Normal and Post-irradiation Conditions (O. D. Kowlessar, Prof. K. I. Altman and L. H. Hempelmann), 867
Urinary Neutral 17-Ketosteroid Conjugates : Enzymatic Hydrolysis of (S. R. Stitch and L. D. K. Halkerston), 398
Urine : Salt Interference in Sugar Chromatography of (Dr. S. Baar and Dr. J. P. Bull), 414
Urine (Human) : Tryptophane Metabolites in (Dr. M. Špaček), 204
Uses of Glycerine . Production and, *review* by Prof. T. P. Hilditch, 1066

Usher, G. : Appointed plant pathologist, Gold Coast, 571
Usher-Wilson, J. M. S. Appointed principal agricultural officer, Nigeria, 234
U.S.S.R. : Re-establishing Scientific Contacts with the (Science for Peace Meeting on), 754
  Research Development in the Machine-Tool Industry of the (W. G. Cass), 64
'Ustin' : Nidulin and, Two Chlorine-containing Metabolic Products of *Aspergillus nidulans* (Dr. F. M. Dean, Prof. A. Robertson, Dr. John C. Roberts and Dr. K. B. Raper), 344
Uterine and Vaginal Receptors during the Menstrual Cycle Variations in the Content of Deoxyribonucleic Acid in the Human (R. Vokaer, Cl. Gompel and A. Ghilain), 31
Utilization of Purines for Nucleic Acid Synthesis in Man (Dr. Leonard Hamilton), 457
Uyeda, S., and others : Origin of Reverse Thermo-remanent Magnetism of Igneous Rocks, 630

VACCINATION of School Children : B. C. G., 941
Vaccines (Aged) : Protective Effect of, on a Neurotropic Virus Infection in Mice (Anne McLaren), 38
Vaeck, S V. : New Method of Direct Quantitative Inorganic Paper Chromatography, 213
Vagal Afferent Fibres Impulses in, from Stretch Receptors in the Stomach and their Role in the Peripheral Mechanism of Hunger (Dr. A. S. Paintal), 1194
Vaginal Cornification of the Mouse produced by Œstrogens *in vitro* (Dr. Margaret H Hardy, Dr. J. D Biggers and P. J. Claringbold), 1196
Vaginal Mucus of the Cow : Extremely High Alkaline Phosphatase Activity in the (Dr. G. A. van Klinkenberg), 397
Vaginal Receptors during the Menstrual Cycle Variations in the Content of Deoxyribonucleic Acid in the Human Uterine and (R. Vokaer, Cl. Gompel and A. Ghilain), 31
Vaginula maculata : Golgi Bodies in the Male Germ-Cells of (Dr M. D. L. Srivastava), 689 ; (Dr. John R Baker), 690
Valentin, Dr. Hartmut . Young Morainic Topography in Holderness, 919
Valle, G. : Ionization Phenomena in Gases, 798
Valonia and *Dictyosphaeria* . Cell-Walls of (F. C. Steward and K. Muhlethaler), 708
Valves (Preferred) : Catalogue of (Scientific Instrument Manufacturers' Association), 985
Van Dyke, Prof E. C. Biologically Active Polypeptides, 1074
Van Gerven, L., and others : Determination of the Structure Factor of Thin Tin Films from Superconductivity Measurements, 952
Van Itterbeek, Prof. A., and others Determination of the Structure Factor of Thin Tin Films from Superconductivity Measurements, 952
Van de Kamer, J. H. : Biochemical Problems of Lipids, 574
Van Vleck, Prof. J. H. : Two Barrier Phenomena (Retiring presidential address to the American Physical Society), 338
Vanadium as an Essential Element for Green Plants (Prof. Daniel I. Arnon and Gunilla Wessel), 1039
Vand, Dr. V. : Calculating Machines, *review*, 371
Vandel, Prof. A. : Laboratoire souterrain at Moulis (Ariège), 829
Vanderplank, Dr. F. L. . Causes of Coconut Nutfall and Gumosis, 315
Vapour-Phase Chromatography : Analytical Separation of the Methyl Esters of the C_{12}–C_{22} Fatty Acids by (F. R. Cropper and A. Heywood), 1101
Vara, P. Biological Rhythms, 943
Varadarajan, S. Awarded an Overseas Scholarship for 1953 by the Royal Commission for the Exhibition of 1851, 17
Variation of Amount of Ozone in the Atmosphere : Daily (Dr. K. R. Ramanathan and Bh. V. Ramana Murthy), 633
Variation in the Incompressibility of an Elastic Material subjected to Large Hydrostatic Pressure (A. Keane), 117
Variation in the Lesser Celandine (A. Mr Perje), 58
Variation in the Regeneration of Root-Cuttings : Seasonal (J. Dore), 1189
Varietal Reaction of Jowar to Grain Smut (P. R. Mehta, Babu Singh, S. C. Mathur and S. B. Singh), 591
Vartiovaara, Unto, and others : *Listeria* Infection in the Guinea Pig caused by Feeding with Aureomycin, 767
Varved Clays from Sweden : Remanent Magnetism of (D. H. Griffiths), 539
Vascular Plants : Comparative Observations on the Shoot Apices of (Prof. C. W. Wardlaw), 1172
Vascular Plants from the Vindhyan System, India : Spores and Tracheids of —the Advent of Vascular Plants (Dr. K. Jacob, Mrs. Chinna Jacob and R. N. Shrivastava), 166
Vascular and Lipoid Pattern of the Adrenal Cortex of the Rat following Hypophysectomy : Changes in the (J. D. Lever, Dr. D. B. Cater and M. P. Stack-Dunne), 33
Vasisth, R. C., and Muthana, Dr. M. S. : A New Method of Separation of Organic Compounds, 862
Vassy, A. and E : Ionization Phenomena in Gases, 799
Vaux, David Hydrography in Fisheries Research, *review*, 179
Veerkamp, Th. A., and Smits, G. : Mode of Action of Beryllium on Alkaline Phosphatase, 589
Vegetable Resources of Great Britain : Animal and (Dr. Thomas Moore), 574
Vegetation : Effects of Atmospheric Pollution on (British Association for the Advancement of Science, Sections K (Botany) and K* (Forestry), Discussion on), 659
Veldstra, Dr. H. : Chemical Structure in relation to Plant Growth-Regulating Activity, 710
Velocity of δ Aquarid Meteors (Mary Almond), 751
Velocity of Sound in Air at Low Pressures (D. E. Caro and Prof. L. H. Martin), 363
Velocity Constant in Chemical Kinetics : Formulation of the (Dr. James C. Robb), 1055
Venables, Dr. P. H. (Heron, Dr. Alastair, and) : Empirical Research in Industry, 898
Vendrely, Dr. R., and Vendrely, C. . Arginine and Deoxyribonucleic Acid Content of Erythrocyte Nuclei and Sperms of some Species of Fishes, 30
Venkataraman, Dr. K. : Higher Technological Education, 270
Venn, Dr. J. A. (compiled by) : Alumni Cantabrigienses, Part 2, From 1752 to 1900, Vol. 5, Pace—Spyers, *review* by Prof. F. J. M. Stratton, 825
Ventricular Nerve Cells in Mammals (Prof. G. A. G. Mitchell, R. Brown an F. B. Cookson), 812
Vermeulen, R. . Sound Recording, 189
Vernalized Grain of Petkus Winter Rye : Acceleration of Flowering in partially, by subsequent Treatment at High Temperature (D. J. C Friend and Prof. F. G. Gregory), 667
Verplanck, Prof W. S. : Rat Behaviour, 489
Verster, Anna J. M. (Wit, Prof. J. J. Duyvené de, and) Observations o *Lebistes reticulatus*, 247
Verulam, Earl of Address at the Annual Conference of the Institute o Personnel Management, 1086
Vestigial Tail in the House Mouse . Linkage between Pulmonary Tumour and (Dr. W. E. Heston), 1007
Veterinary Department, Nyasaland : Appointment of F. W. Will as live stock marketing officer, 234
Vibe, Chr. : Zoogeography of Greenland, 829
Vice-Chancellorship of the University of Birmingham, 1170
Vice-Chancellorship of the University of Otago, 1170
Vijayaraghavan, P K., and Narasinga Rao, B. S. : Action of Duck's Eg White Ovomucoid on Tryptic Hydrolysis of Casein *in vitro*, 1152
Village : Birds of Town and (R. S. R. Fitter), *review* by L. J. F. Brimble, 324
Villax, Prof. Edmond, and Mota, Miguel: Behaviour of a *Triticum* × *Secale* Hybrid under the Action of Colchicine, 412
Vincent, Miss M. A *Chaloropsis* on Beech, 963
Vindhyan System, India : Spores and Tracheids of Vascular Plants from the —the Advent of Vascular Plants (Dr. K. Jacob, Mrs. Chinna Jaco and R N. Shrivastava), 166
Viral Enzyme Presence of 2-Carboxy-pyrrole in Mucoproteins and it Relation to the (Dr. A. Gottschalk), 808
Virulence of *Rhizobium trifolii* : Influence of Rhizosphere Micro-organisms on the (J. R. Harris), 507
Virus (Ectromelia) . Growth Cycle of, in Mouse Liver (G. J. V. Nossal and Prof. P. M. de Burgh), 671
Virus (Fowl Plague) Effect of Five Strains of, on a Sulphonphthalein Dy (Dr. M. K. Tolba and Mrs. Josephine K. Eskarous), 961
Virus (Infectious Laryngotracheitis) : Possible *P–Q* Type Variation in (M. F Pulsford), 1193
Virus Production . Absence of 'Incomplete', in certain Influenza Strains (Dr. S. Fazekas de St. Groth and Miss Doris M. Graham), 1193
Virus in the Cell Nucleus : Development of (Dr. Kenneth M. Smith and N. Xeros), 670
Virus of Tomato Spotted Wilt in Dried Plant Material : Preservation of the (Dr. Rupert J. Best and H. P C. Gallus), 315
Virus-diseased Cells of Lepidopterous Larvæ : Development of Intranuclear Inclusions in (N. Xeros), 309
Virus *X*-saturated Potato Varieties : Reconstitution of, with Malachit Green (Dr. D. Norris), 816
Virus Antigen (Tobacco Mosaic) Radioautographic Study of the Localization of (Dr. F. Gavosto and Mrs. A. Ficq), 406
Virus Bundles in Nuclear Polyhedroses Origin and Fate of the (N. Xeros), 548
Virus Infection in Mice : Protective Effect of Aged Vaccines on a Neurotropic (Anne McLaren), 38
Viruses . Nature and Constitution of (Society for Visiting Scientists Symposium on), 105
Viruses (Animal) : Weight Relationships among (Dr. Alfred Polson), 1154
Viruses (Influenza) A Host-Protein Component of (Prof. Wilson Smith, G. Belyavin and F W. Sheffield), 669
Vision through the Atmosphere (W. E. Knowles Middleton), *review* by Dr. John W. T. Walsh, 1118
Vision Defect (Colour-) . A Pedigree for Three Types of (Dr. R. W. Pickford), 1010
Visiting Scientists, Society for : Symposium on the Nature and Constitution of Viruses, 105
Visitors' Tables at Colonial Fisheries Research Stations (Dr. C. F. Hickling), 885
Visual Binaries : Orientation of the Orbital Planes of the (A. Opolski), 526
Visual Purple : Human (Dr F. Crescitelli and Dr. H. J. A. Dartnall), 195
Visual Purple in Solution : Effect of Melanophore Hormone on Regeneration of (Prof. Toshimasa Hanaoka), 866
Vitamin A Deficiency in Rats : Aspects of (J. S. Lowe, Prof. R. A. Morton and Prof. R. G. Harrison), 716
Vitamin A Esterase Activity in Rat Liver : Intracellular Distribution of (Dr. J. Ganguly and Prof. H. J Deuel, Jun.), 120
Vitamin B Group : Synthesis of Components of the, by *Corynebacterium diphtheriae* (Lauri Hinnes), 400
B-Vitamins in Wheat—the Unique Aleurone Layer (Dr. J. J. C. Hinton, F. G. Peers and Dr. B. Shaw), 993
Vivian, H. E. (Alexander, K. M., and) : Pozzolanic Activity of Ash produced by the Eruption of Mt. Lamington, New Guinea, 1002
Vlček, Dr. A. A. : Polarographic Effect of Carbon Dioxide in Solutions of Ethyl Alcohol, 861
Vliegenthart, J. A., and others : A Precursor of Methoxy-*para*-benzoquinone in Wheat Germ, 402
Vokaer, R., and others : Variations in the Content of Deoxyribonucleic Acid in the Human Uterine and Vaginal Receptors during the Menstrual Cycle, 31
Vortex : Axial Flow in a (John B. Nuttall), 582
Votava, E. (Amelinckx, S., and) : Relation between Frank Spirals and Spiral Pits in Crystals, 538
Vries, Miss Jeane T. de : Diacetyl as a Flower Scent, 412
Vuylsteke, C. A. . At the XIX International Physiological Congress, Montreal, 1073

WACE, Prof. A. J. B. : Excavations at Mycenæ, 525
Wacholder, K. : Biological Rhythms, 943
Wachtmeister, Carl-Axel (Erdtman, Prof. Holger, and) : Structure of Porphyrilic Acid, 724
Waddington, Prof. C. H. : Role of Plasmagenes, *review*, 784
Waddington, Prof. C. H., and Pantelouris, E. M. : Transplantation of Nuclei in Newt's Eggs, 1050
Wadsley, A D. : Interstitial Atoms in the Layer Structure $ZnMn_3O_7 3H_2O$ (Chalcophanite), 1103, erratum, 1173
